# Introduction to ASP.NET Core

6/28/2018 • 2 minutes to read • [Edit Online](#)

By [Daniel Roth](#), [Rick Anderson](#), and [Shaun Luttin](#)

ASP.NET Core is a cross-platform, high-performance, [open-source](#) framework for building modern, cloud-based, Internet-connected applications. With ASP.NET Core, you can:

- Build web apps and services, [IoT](#) apps, and mobile backends.
- Use your favorite development tools on Windows, macOS, and Linux.
- Deploy to the cloud or on-premises.
- Run on [.NET Core](#) or [.NET Framework](#).

## Why use ASP.NET Core?

Millions of developers have used (and continue to use) [ASP.NET 4.x](#) to create web apps. ASP.NET Core is a redesign of ASP.NET 4.x, with architectural changes that result in a leaner, more modular framework.

ASP.NET Core provides the following benefits:

- A unified story for building web UI and web APIs.
- Integration of [modern, client-side frameworks](#) and development workflows.
- A cloud-ready, environment-based [configuration system](#).
- Built-in [dependency injection](#).
- A lightweight, [high-performance](#), and modular HTTP request pipeline.
- Ability to host on [IIS](#), [Nginx](#), [Apache](#), [Docker](#), or self-host in your own process.
- Side-by-side app versioning when targeting [.NET Core](#).
- Tooling that simplifies modern web development.
- Ability to build and run on Windows, macOS, and Linux.
- Open-source and [community-focused](#).

ASP.NET Core ships entirely as [NuGet](#) packages. Using NuGet packages allows you to optimize your app to include only the necessary dependencies. In fact, ASP.NET Core 2.x apps targeting .NET Core only require a [single NuGet package](#). The benefits of a smaller app surface area include tighter security, reduced servicing, and improved performance.

## Build web APIs and web UI using ASP.NET Core MVC

ASP.NET Core MVC provides features to build [web APIs](#) and [web apps](#):

- The [Model-View-Controller \(MVC\)](#) pattern helps make your web APIs and web apps [testable](#).
- [Razor Pages](#) (new in ASP.NET Core 2.0) is a page-based programming model that makes building web UI easier and more productive.
- [Razor markup](#) provides a productive syntax for [Razor Pages](#) and [MVC views](#).
- [Tag Helpers](#) enable server-side code to participate in creating and rendering HTML elements in Razor files.
- Built-in support for [multiple data formats and content negotiation](#) lets your web APIs reach a broad range of clients, including browsers and mobile devices.
- [Model binding](#) automatically maps data from HTTP requests to action method parameters.
- [Model validation](#) automatically performs client- and server-side validation.

## Client-side development

ASP.NET Core integrates seamlessly with popular client-side frameworks and libraries, including [Angular](#), [React](#), and [Bootstrap](#). For more information, see [Client-side development](#).

## ASP.NET Core targeting .NET Framework

ASP.NET Core can target .NET Core or .NET Framework. ASP.NET Core apps targeting .NET Framework aren't cross-platform—they run on Windows only. There are no plans to remove support for targeting .NET Framework in ASP.NET Core. Generally, ASP.NET Core is made up of [.NET Standard](#) libraries. Apps written with .NET Standard 2.0 run anywhere that .NET Standard 2.0 is supported.

There are several advantages to targeting .NET Core, and these advantages increase with each release. Some advantages of .NET Core over .NET Framework include:

- Cross-platform. Runs on macOS, Linux, and Windows.
- Improved performance
- Side-by-side versioning
- New APIs
- Open source

We're working hard to close the API gap from .NET Framework to .NET Core. The [Windows Compatibility Pack](#) made thousands of Windows-only APIs available in .NET Core. These APIs weren't available in .NET Core 1.x.

## Next steps

For more information, see the following resources:

- [Get started with Razor Pages](#)
- [ASP.NET Core tutorials](#)
- [ASP.NET Core fundamentals](#)
- [The weekly ASP.NET community standup](#) covers the team's progress and plans. It features new blogs and third-party software.

# What's new in ASP.NET Core 2.1

6/28/2018 • 6 minutes to read • [Edit Online](#)

This article highlights the most significant changes in ASP.NET Core 2.1, with links to relevant documentation.

## SignalR

SignalR has been rewritten for ASP.NET Core 2.1. ASP.NET Core SignalR includes a number of improvements:

- A simplified scale-out model.
- A new JavaScript client with no jQuery dependency.
- A new compact binary protocol based on MessagePack.
- Support for custom protocols.
- A new streaming response model.
- Support for clients based on bare WebSockets.

For more information, see [ASP.NET Core SignalR](#).

## Razor class libraries

ASP.NET Core 2.1 makes it easier to build and include Razor-based UI in a library and share it across multiple projects. The new Razor SDK enables building Razor files into a class library project that can be packaged into a NuGet package. Views and pages in libraries are automatically discovered and can be overridden by the app. By integrating Razor compilation into the build:

- The app startup time is significantly faster.
- Fast updates to Razor views and pages at runtime are still available as part of an iterative development workflow.

For more information, see [Create reusable UI using the Razor Class Library project](#).

## Identity UI library & scaffolding

ASP.NET Core 2.1 provides [ASP.NET Core Identity](#) as a [Razor Class Library](#). Apps that include Identity can apply the new Identity scaffolder to selectively add the source code contained in the Identity Razor Class Library (RCL). You might want to generate source code so you can modify the code and change the behavior. For example, you could instruct the scaffolder to generate the code used in registration. Generated code takes precedence over the same code in the Identity RCL.

Apps that do **not** include authentication can apply the Identity scaffolder to add the RCL Identity package. You have the option of selecting Identity code to be generated.

For more information, see [Scaffold Identity in ASP.NET Core projects](#).

## HTTPS

With the increased focus on security and privacy, enabling HTTPS for web apps is important. HTTPS enforcement is becoming increasingly strict on the web. Sites that don't use HTTPS are considered insecure. Browsers (Chromium, Mozilla) are starting to enforce that web features must be used from a secure context. [GDPR](#) requires the use of HTTPS to protect user privacy. While using HTTPS in production is critical, using HTTPS in development can help prevent issues in deployment (for example, insecure links). ASP.NET Core 2.1 includes a number of

improvements that make it easier to use HTTPS in development and to configure HTTPS in production. For more information, see [Enforce HTTPS](#).

## On by default

To facilitate secure website development, HTTPS is now enabled by default. Starting in 2.1, Kestrel listens on `https://localhost:5001` when a local development certificate is present. A development certificate is created:

- As part of the .NET Core SDK first-run experience, when you use the SDK for the first time.
- Manually using the new `dotnet dev-certs` tool.

Run `dotnet dev-certs https --trust` to trust the certificate.

## HTTPS redirection and enforcement

Web apps typically need to listen on both HTTP and HTTPS, but then redirect all HTTP traffic to HTTPS. In 2.1, specialized HTTPS redirection middleware that intelligently redirects based on the presence of configuration or bound server ports has been introduced.

Use of HTTPS can be further enforced using [HTTP Strict Transport Security Protocol \(HSTS\)](#). HSTS instructs browsers to always access the site via HTTPS. ASP.NET Core 2.1 adds HSTS middleware that supports options for max age, subdomains, and the HSTS preload list.

## Configuration for production

In production, HTTPS must be explicitly configured. In 2.1, default configuration schema for configuring HTTPS for Kestrel has been added. Apps can be configured to use:

- Multiple endpoints including the URLs. For more information, see [Kestrel web server implementation: Endpoint configuration](#).
- The certificate to use for HTTPS either from a file on disk or from a certificate store.

## GDPR

ASP.NET Core provides APIs and templates to help meet some of the [EU General Data Protection Regulation \(GDPR\)](#) requirements. For more information, see [GDPR support in ASP.NET Core](#). A [sample app](#) shows how to use and lets you test most of the GDPR extension points and APIs added to the ASP.NET Core 2.1 templates.

## Integration tests

A new package is introduced that streamlines test creation and execution. The [Microsoft.AspNetCore.Mvc.Testing](#) package handles the following tasks:

- Copies the dependency file (`*.deps`) from the tested app into the test project's `bin` folder.
- Sets the content root to the tested app's project root so that static files and pages/views are found when the tests are executed.
- Provides the `WebApplicationFactory` class to streamline bootstrapping the tested app with `TestServer`.

The following test uses [xUnit](#) to check that the Index page loads with a success status code and with the correct Content-Type header:

```

public class BasicTests
    : IClassFixture<WebApplicationFactory<RazorPagesProject.Startup>>
{
    private readonly HttpClient _client;

    public BasicTests(WebApplicationFactory<RazorPagesProject.Startup> factory)
    {
        _client = factory.CreateClient();
    }

    [Fact]
    public async Task GetHomePage()
    {
        // Act
        var response = await _client.GetAsync("/");

        // Assert
        response.EnsureSuccessStatusCode(); // Status Code 200-299
        Assert.Equal("text/html; charset=utf-8",
            response.Content.Headers.ContentType.ToString());
    }
}

```

For more information, see the [Integration tests](#) topic.

## [ApiController], ActionResult

ASP.NET Core 2.1 adds new programming conventions that make it easier to build clean and descriptive web APIs. `ActionResult<T>` is a new type added to allow an app to return either a response type or any other action result (similar to `IActionResult`), while still indicating the response type. The `[ApiController]` attribute has also been added as the way to opt in to Web API-specific conventions and behaviors.

For more information, see [Build Web APIs with ASP.NET Core](#).

## IHttpClientFactory

ASP.NET Core 2.1 includes a new `IHttpClientFactory` service that makes it easier to configure and consume instances of `HttpClient` in apps. `HttpClient` already has the concept of delegating handlers that could be linked together for outgoing HTTP requests. The factory:

- Makes registering of instances of `HttpClient` per named client more intuitive.
- Implements a Polly handler that allows Polly policies to be used for Retry, CircuitBreakers, etc.

For more information, see [Initiate HTTP Requests](#).

## Kestrel transport configuration

With the release of ASP.NET Core 2.1, Kestrel's default transport is no longer based on Libuv but instead based on managed sockets. For more information, see [Kestrel web server implementation: Transport configuration](#).

## Generic host builder

The Generic Host Builder (`HostBuilder`) has been introduced. This builder can be used for apps that don't process HTTP requests (Messaging, background tasks, etc.).

For more information, see [.NET Generic Host](#).

## Updated SPA templates

The Single Page Application templates for Angular, React, and React with Redux are updated to use the standard project structures and build systems for each framework.

The Angular template is based on the Angular CLI, and the React templates are based on `create-react-app`. For more information, see [Use the Single Page Application templates with ASP.NET Core](#).

## Razor Pages search for Razor assets

In 2.1, Razor Pages search for Razor assets (such as layouts and partials) in the following directories in the listed order:

1. Current Pages folder.
2. `/Pages/Shared/`
3. `/Views/Shared/`

## Razor Pages in an area

Razor Pages now support [areas](#). To see an example of areas, create a new Razor Pages web app with individual user accounts. A Razor Pages web app with individual user accounts includes `/Areas/Identity/Pages`.

## Migrate from 2.0 to 2.1

See [Migrate from ASP.NET Core 2.0 to 2.1](#).

## Additional information

For the complete list of changes, see the [ASP.NET Core 2.1 Release Notes](#).

# What's new in ASP.NET Core 2.0

6/28/2018 • 5 minutes to read • [Edit Online](#)

This article highlights the most significant changes in ASP.NET Core 2.0, with links to relevant documentation.

## Razor Pages

Razor Pages is a new feature of ASP.NET Core MVC that makes coding page-focused scenarios easier and more productive.

For more information, see the introduction and tutorial:

- [Introduction to Razor Pages](#)
- [Get started with Razor Pages](#)

## ASP.NET Core metapackage

A new ASP.NET Core metapackage includes all of the packages made and supported by the ASP.NET Core and Entity Framework Core teams, along with their internal and 3rd-party dependencies. You no longer need to choose individual ASP.NET Core features by package. All features are included in the [Microsoft.AspNetCore.All](#) package. The default templates use this package.

For more information, see [Microsoft.AspNetCore.All metapackage for ASP.NET Core 2.0](#).

## Runtime Store

Applications that use the `Microsoft.AspNetCore.All` metapackage automatically take advantage of the new .NET Core Runtime Store. The Store contains all the runtime assets needed to run ASP.NET Core 2.0 applications. When you use the `Microsoft.AspNetCore.All` metapackage, no assets from the referenced ASP.NET Core NuGet packages are deployed with the application because they already reside on the target system. The assets in the Runtime Store are also precompiled to improve application startup time.

For more information, see [Runtime store](#)

## .NET Standard 2.0

The ASP.NET Core 2.0 packages target .NET Standard 2.0. The packages can be referenced by other .NET Standard 2.0 libraries, and they can run on .NET Standard 2.0-compliant implementations of .NET, including .NET Core 2.0 and .NET Framework 4.6.1.

The `Microsoft.AspNetCore.All` metapackage targets .NET Core 2.0 only, because it's intended to be used with the .NET Core 2.0 Runtime Store.

## Configuration update

An `IConfiguration` instance is added to the services container by default in ASP.NET Core 2.0. `IConfiguration` in the services container makes it easier for applications to retrieve configuration values from the container.

For information about the status of planned documentation, see the [GitHub issue](#).

## Logging update

In ASP.NET Core 2.0, logging is incorporated into the dependency injection (DI) system by default. You add providers and configure filtering in the *Program.cs* file instead of in the *Startup.cs* file. And the default `ILoggerFactory` supports filtering in a way that lets you use one flexible approach for both cross-provider filtering and specific-provider filtering.

For more information, see [Introduction to Logging](#).

## Authentication update

A new authentication model makes it easier to configure authentication for an application using DI.

New templates are available for configuring authentication for web apps and web APIs using [Azure AD B2C] (<https://azure.microsoft.com/services/active-directory-b2c/>).

For information about the status of planned documentation, see the [GitHub issue](#).

## Identity update

We've made it easier to build secure web APIs using Identity in ASP.NET Core 2.0. You can acquire access tokens for accessing your web APIs using the [Microsoft Authentication Library \(MSAL\)](#).

For more information on authentication changes in 2.0, see the following resources:

- [Account confirmation and password recovery in ASP.NET Core](#)
- [Enable QR Code generation for authenticator apps in ASP.NET Core](#)
- [Migrate Authentication and Identity to ASP.NET Core 2.0](#)

## SPA templates

Single Page Application (SPA) project templates for Angular, Aurelia, Knockout.js, React.js, and React.js with Redux are available. The Angular template has been updated to Angular 4. The Angular and React templates are available by default; for information about how to get the other templates, see [Create a new SPA project](#). For information about how to build a SPA in ASP.NET Core, see [Use JavaScriptServices for Creating Single Page Applications](#).

## Kestrel improvements

The Kestrel web server has new features that make it more suitable as an Internet-facing server. A number of server constraint configuration options are added in the `KestrelServerOptions` class's new `Limits` property. Add limits for the following:

- Maximum client connections
- Maximum request body size
- Minimum request body data rate

For more information, see [Kestrel web server implementation in ASP.NET Core](#).

## WebListener renamed to HTTP.sys

The packages `Microsoft.AspNetCore.Server.WebListener` and `Microsoft.Net.Http.Server` have been merged into a new package `Microsoft.AspNetCore.Server.HttpSys`. The namespaces have been updated to match.

For more information, see [HTTP.sys web server implementation in ASP.NET Core](#).

## Enhanced HTTP header support

When using MVC to transmit a `FileStreamResult` or a `FileContentResult`, you now have the option to set an

`ETag` or a `LastModified` date on the content you transmit. You can set these values on the returned content with code similar to the following:

```
var data = Encoding.UTF8.GetBytes("This is a sample text from a binary array");
var entityTag = new EntityTagHeaderValue("\"MyCalculatedEtagValue\"");
return File(data, "text/plain", "downloadName.txt", lastModified: DateTime.UtcNow.AddSeconds(-5), entityTag:
entityTag);
```

The file returned to your visitors will be decorated with the appropriate HTTP headers for the `ETag` and `LastModified` values.

If an application visitor requests content with a Range Request header, ASP.NET will recognize that and handle that header. If the requested content can be partially delivered, ASP.NET will appropriately skip and return just the requested set of bytes. You don't need to write any special handlers into your methods to adapt or handle this feature; it's automatically handled for you.

## Hosting startup and Application Insights

Hosting environments can now inject extra package dependencies and execute code during application startup, without the application needing to explicitly take a dependency or call any methods. This feature can be used to enable certain environments to "light-up" features unique to that environment without the application needing to know ahead of time.

In ASP.NET Core 2.0, this feature is used to automatically enable Application Insights diagnostics when debugging in Visual Studio and (after opting in) when running in Azure App Services. As a result, the project templates no longer add Application Insights packages and code by default.

For information about the status of planned documentation, see the [GitHub issue](#).

## Automatic use of anti-forgery tokens

ASP.NET Core has always helped HTML-encode content by default, but with the new version an extra step is taken to help prevent cross-site request forgery (XSRF) attacks. ASP.NET Core will now emit anti-forgery tokens by default and validate them on form POST actions and pages without extra configuration.

For more information, see [Prevent Cross-Site Request Forgery \(XSRF/CSRF\) attacks](#).

## Automatic precompilation

Razor view pre-compilation is enabled during publish by default, reducing the publish output size and application startup time.

For more information, see [Razor view compilation and precompilation in ASP.NET Core](#).

## Razor support for C# 7.1

The Razor view engine has been updated to work with the new Roslyn compiler. That includes support for C# 7.1 features like Default Expressions, Inferred Tuple Names, and Pattern-Matching with Generics. To use C# 7.1 in your project, add the following property in your project file and then reload the solution:

```
<LangVersion>latest</LangVersion>
```

For information about the status of C# 7.1 features, see [the Roslyn GitHub repository](#).

## Other documentation updates for 2.0

- [Visual Studio publish profiles for ASP.NET Core app deployment](#)
- [Key Management](#)
- [Configure Facebook authentication](#)
- [Configure Twitter authentication](#)
- [Configure Google authentication](#)
- [Configure Microsoft Account authentication](#)

## Migration guidance

For guidance on how to migrate ASP.NET Core 1.x applications to ASP.NET Core 2.0, see the following resources:

- [Migrate from ASP.NET Core 1.x to ASP.NET Core 2.0](#)
- [Migrate Authentication and Identity to ASP.NET Core 2.0](#)

## Additional Information

For the complete list of changes, see the [ASP.NET Core 2.0 Release Notes](#).

To connect with the ASP.NET Core development team's progress and plans, tune in to the [ASP.NET Community Standup](#).

# What's new in ASP.NET Core 1.1

6/28/2018 • 2 minutes to read • [Edit Online](#)

ASP.NET Core 1.1 includes the following new features:

- [URL Rewriting Middleware](#)
- [Response Caching Middleware](#)
- [View Components as Tag Helpers](#)
- [Middleware as MVC filters](#)
- [Cookie-based TempData provider](#)
- [Azure App Service logging provider](#)
- [Azure Key Vault configuration provider](#)
- [Azure and Redis Storage Data Protection Key Repositories](#)
- [WebListener Server for Windows](#)
- [WebSockets support](#)

## Choosing between versions 1.0 and 1.1 of ASP.NET Core

ASP.NET Core 1.1 has more features than 1.0. In general, we recommend you use the latest version.

## Additional Information

- [ASP.NET Core 1.1.0 Release Notes](#)
- To connect with the ASP.NET Core development team's progress and plans, tune in to the [ASP.NET Community Standup](#).

# Get started with ASP.NET Core

6/28/2018 • 2 minutes to read • [Edit Online](#)

1. Install the [.NET Core 2.1 SDK or later](#).
2. Create an ASP.NET Core project. Open a command shell and enter the following command:

```
dotnet new webapp -o aspnetcoreapp
```

## NOTE

In ASP.NET Core 2.1 or later, `webapp` is an alias of the `razor` argument. If the `dotnet new webapp <OPTIONS>` command loads the `dotnet new` command help instead of creating a new Razor Pages app, install the [.NET Core 2.1 SDK](#).

3. Trust the HTTPS development certificate:

- [Windows](#)
- [macOS](#)
- [Linux](#)

```
dotnet dev-certs https --trust
```

The preceding command displays the following dialog:

Select **Yes** if you agree to trust the development certificate.

1. Install the [.NET Core SDK 2.0 or later](#).
2. Create a new ASP.NET Core project.

Open a command shell. Enter the following command:

```
dotnet new razor -o aspnetcoreapp
```

- Run the app with the following commands:

```
cd aspnetcoreapp  
dotnet run
```

- Browse to <http://localhost:5000>.

- Open *Pages/About.cshtml* and modify the page to display the message "Hello, world! The time on the server is @DateTime.Now":

```
@page  
@model AboutModel  
{  
    ViewData["Title"] = "About";  
}  
<h2>@ViewData["Title"]</h2>  
<h3>@Model.Message</h3>  
  
<p>Hello, world! The time on the server is @DateTime.Now</p>
```

- Browse to <http://localhost:5000/About> and verify the changes.

## Next steps

- An ASP.NET Core app can use the .NET Core or .NET Framework Base Class Library and runtime. For more information, see [Choosing between .NET Core and .NET Framework](#).
- [Getting started tutorials](#)
- [Introduction to ASP.NET Core](#)
- [ASP.NET Core architecture and fundamentals](#).

- Install the .NET Core **SDK Installer** for SDK 1.0.4 from the [.NET Core All Downloads](#) page.

- Create a folder for a new ASP.NET Core project.

Open a command shell. Enter the following commands:

```
mkdir aspnetcoreapp  
cd aspnetcoreapp
```

- If you have installed a later SDK version on your machine, create a *global.json* file to select the 1.0.4 SDK.

```
{  
    "sdk": { "version": "1.0.4" }  
}
```

- Create a new ASP.NET Core project.

```
dotnet new web
```

- Restore the packages.

```
dotnet restore
```

## 6. Run the app.

```
dotnet run
```

The [dotnet run](#) command builds the app first, if needed.

## 7. Browse to <http://localhost:5000>.

### Next steps

- An ASP.NET Core app can use the .NET Core or .NET Framework Base Class Library and runtime. For more information, see [Choosing between .NET Core and .NET Framework](#).
- [Getting started tutorials](#)
- [Introduction to ASP.NET Core](#)
- [ASP.NET Core architecture and fundamentals](#).

# Introduction to Razor Pages in ASP.NET Core

7/6/2018 • 20 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Ryan Nowak](#)

Razor Pages is a new aspect of ASP.NET Core MVC that makes coding page-focused scenarios easier and more productive.

If you're looking for a tutorial that uses the Model-View-Controller approach, see [Get started with ASP.NET Core MVC](#).

This document provides an introduction to Razor Pages. It's not a step by step tutorial. If you find some of the sections too advanced, see [Get started with Razor Pages](#). For an overview of ASP.NET Core, see the [Introduction to ASP.NET Core](#).

## Prerequisites

Install **one** of the following:

- CLI tooling: Windows, Linux, or macOS: [.NET Core SDK 2.0 or later](#)
- IDE/editor tooling
  - Windows: [Visual Studio for Windows](#)
    - **ASP.NET and web development** workload
    - **.NET Core cross-platform development** workload
  - Linux: [Visual Studio Code](#)
  - macOS: [Visual Studio for Mac](#)

## Creating a Razor Pages project

- [Visual Studio](#)
- [Visual Studio for Mac](#)
- [Visual Studio Code](#)
- [.NET Core CLI](#)

See [Get started with Razor Pages](#) for detailed instructions on how to create a Razor Pages project using Visual Studio.

## Razor Pages

Razor Pages is enabled in *Startup.cs*:

```

public class Startup
{
    public void ConfigureServices(IServiceCollection services)
    {
        // Includes support for Razor Pages and controllers.
        services.AddMvc();
    }

    public void Configure(IApplicationBuilder app)
    {
        app.UseMvc();
    }
}

```

Consider a basic page:

```

@page

<h1>Hello, world!</h1>
<h2>The time on the server is @DateTime.Now</h2>

```

The preceding code looks a lot like a Razor view file. What makes it different is the `@page` directive. `@page` makes the file into an MVC action - which means that it handles requests directly, without going through a controller.

`@page` must be the first Razor directive on a page. `@page` affects the behavior of other Razor constructs.

A similar page, using a `PageModel` class, is shown in the following two files. The *Pages/Index2.cshtml* file:

```

@page
@using RazorPagesIntro.Pages
@model IndexModel2

<h2>Separate page model</h2>
<p>
    @Model.Message
</p>

```

The *Pages/Index2.cshtml.cs* page model:

```

using Microsoft.AspNetCore.Mvc.RazorPages;
using System;

namespace RazorPagesIntro.Pages
{
    public class IndexModel2 : PageModel
    {
        public string Message { get; private set; } = "PageModel in C#";

        public void OnGet()
        {
            Message += $" Server time is { DateTime.Now }";
        }
    }
}

```

By convention, the `PageModel` class file has the same name as the Razor Page file with `.cs` appended. For example, the previous Razor Page is *Pages/Index2.cshtml*. The file containing the `PageModel` class is named *Pages/Index2.cshtml.cs*.

The associations of URL paths to pages are determined by the page's location in the file system. The following table

shows a Razor Page path and the matching URL:

FILE NAME AND PATH	MATCHING URL
/Pages/Index.cshtml	/ or /Index
/Pages/Contact.cshtml	/Contact
/Pages/Store/Contact.cshtml	/Store/Contact
/Pages/Store/Index.cshtml	/Store or /Store/Index

Notes:

- The runtime looks for Razor Pages files in the *Pages* folder by default.
- `Index` is the default page when a URL doesn't include a page.

## Writing a basic form

Razor Pages is designed to make common patterns used with web browsers easy to implement when building an app. [Model binding](#), [Tag Helpers](#), and HTML helpers all *just work* with the properties defined in a Razor Page class. Consider a page that implements a basic "contact us" form for the `Contact` model:

For the samples in this document, the `DbContext` is initialized in the [Startup.cs](#) file.

```
using Microsoft.AspNetCore.Builder;
using Microsoft.AspNetCore.Hosting;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using RazorPagesContacts.Data;

namespace RazorPagesContacts
{
    public class Startup
    {
        public IHostingEnvironment HostingEnvironment { get; }

        public void ConfigureServices(IServiceCollection services)
        {
            services.AddDbContext<AppDbContext>(options =>
                options.UseInMemoryDatabase("name"));
            services.AddMvc();
        }

        public void Configure(IApplicationBuilder app)
        {
            app.UseMvc();
        }
    }
}
```

The data model:

```

using System.ComponentModel.DataAnnotations;

namespace RazorPagesContacts.Data
{
    public class Customer
    {
        public int Id { get; set; }

        [Required, StringLength(100)]
        public string Name { get; set; }
    }
}

```

The db context:

```

using Microsoft.EntityFrameworkCore;

namespace RazorPagesContacts.Data
{
    public class AppDbContext : DbContext
    {
        public AppDbContext(DbContextOptions options)
            : base(options)
        {
        }

        public DbSet<Customer> Customers { get; set; }
    }
}

```

The *Pages/Create.cshtml* view file:

```

@page
@model RazorPagesContacts.Pages.CreateModel
@addTagHelper *, Microsoft.AspNetCore.Mvc.TagHelpers

<html>
<body>
    <p>
        Enter your name.
    </p>
    <div asp-validation-summary="All"></div>
    <form method="POST">
        <div>Name: <input asp-for="Customer.Name" /></div>
        <input type="submit" />
    </form>
</body>
</html>

```

The *Pages/Create.cshtml.cs* page model:

```

using System.Threading.Tasks;
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using RazorPagesContacts.Data;

namespace RazorPagesContacts.Pages
{
    public class CreateModel : PageModel
    {
        private readonly ApplicationDbContext _db;

        public CreateModel(ApplicationDbContext db)
        {
            _db = db;
        }

        [BindProperty]
        public Customer Customer { get; set; }

        public async Task<IActionResult> OnPostAsync()
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }

            _db.Customers.Add(Customer);
            await _db.SaveChangesAsync();
            return RedirectToPage("/Index");
        }
    }
}

```

By convention, the `PageModel` class is called `<PageName>Model` and is in the same namespace as the page.

The `PageModel` class allows separation of the logic of a page from its presentation. It defines page handlers for requests sent to the page and the data used to render the page. This separation allows you to manage page dependencies through [dependency injection](#) and to [unit test](#) the pages.

The page has an `OnPostAsync` *handler method*, which runs on `POST` requests (when a user posts the form). You can add handler methods for any HTTP verb. The most common handlers are:

- `OnGet` to initialize state needed for the page. [OnGet sample](#).
- `OnPost` to handle form submissions.

The `Async` naming suffix is optional but is often used by convention for asynchronous functions. The `OnPostAsync` code in the preceding example looks similar to what you would normally write in a controller. The preceding code is typical for Razor Pages. Most of the MVC primitives like [model binding](#), [validation](#), and action results are shared.

The previous `OnPostAsync` method:

```

public async Task<IActionResult> OnPostAsync()
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    _db.Customers.Add(Customer);
    await _db.SaveChangesAsync();
    return RedirectToPage("/Index");
}

```

The basic flow of `OnPostAsync`:

Check for validation errors.

- If there are no errors, save the data and redirect.
- If there are errors, show the page again with validation messages. Client-side validation is identical to traditional ASP.NET Core MVC applications. In many cases, validation errors would be detected on the client, and never submitted to the server.

When the data is entered successfully, the `OnPostAsync` handler method calls the `RedirectToPage` helper method to return an instance of `RedirectToPageResult`. `RedirectToPage` is a new action result, similar to `RedirectToAction` or `RedirectToRoute`, but customized for pages. In the preceding sample, it redirects to the root Index page (`/Index`). `RedirectToPage` is detailed in the [URL generation for Pages](#) section.

When the submitted form has validation errors (that are passed to the server), the `OnPostAsync` handler method calls the `Page` helper method. `Page` returns an instance of `PageResult`. Returning `Page` is similar to how actions in controllers return `View`. `PageResult` is the default return type for a handler method. A handler method that returns `void` renders the page.

The `Customer` property uses `[BindProperty]` attribute to opt in to model binding.

```
public class CreateModel : PageModel
{
    private readonly AppDbContext _db;

    public CreateModel(AppDbContext db)
    {
        _db = db;
    }

    [BindProperty]
    public Customer Customer { get; set; }

    public async Task<IActionResult> OnPostAsync()
    {
        if (!ModelState.IsValid)
        {
            return Page();
        }

        _db.Customers.Add(Customer);
        await _db.SaveChangesAsync();
        return RedirectToPage("/Index");
    }
}
```

Razor Pages, by default, bind properties only with non-GET verbs. Binding to properties can reduce the amount of code you have to write. Binding reduces code by using the same property to render form fields (

`<input asp-for="Customer.Name" />`) and accept the input.

#### NOTE

For security reasons, you must opt in to binding GET request data to page model properties. Verify user input before mapping it to properties. Opting in to this behavior is useful when addressing scenarios which rely on query string or route values.

To bind a property on GET requests, set the `[BindProperty]` attribute's `SupportsGet` property to `true`:

```
[BindProperty(SupportsGet = true)]
```

The home page (*Index.cshtml*):

```
@page
@model RazorPagesContacts.Pages.IndexModel
@addTagHelper *, Microsoft.AspNetCore.Mvc.TagHelpers

<h1>Contacts</h1>
<form method="post">
    <table class="table">
        <thead>
            <tr>
                <th>ID</th>
                <th>Name</th>
            </tr>
        </thead>
        <tbody>
            @foreach (var contact in Model.Customers)
            {
                <tr>
                    <td>@contact.Id</td>
                    <td>@contact.Name</td>
                    <td>
                        <a asp-page=".Edit" asp-route-id="@contact.Id">edit</a>
                        <button type="submit" asp-page-handler="delete"
                                asp-route-id="@contact.Id">delete</button>
                    </td>
                </tr>
            }
        </tbody>
    </table>

    <a asp-page=".Create">Create</a>
</form>
```

The associated `PageModel` class (*Index.cshtml.cs*):

```

using System.Threading.Tasks;
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using RazorPagesContacts.Data;
using System.Collections.Generic;
using Microsoft.EntityFrameworkCore;

namespace RazorPagesContacts.Pages
{
    public class IndexModel : PageModel
    {
        private readonly AppDbContext _db;

        public IndexModel(AppDbContext db)
        {
            _db = db;
        }

        public IList<Customer> Customers { get; private set; }

        public async Task OnGetAsync()
        {
            Customers = await _db.Customers.AsNoTracking().ToListAsync();
        }

        public async Task<IActionResult> OnPostDeleteAsync(int id)
        {
            var contact = await _db.Customers.FindAsync(id);

            if (contact != null)
            {
                _db.Customers.Remove(contact);
                await _db.SaveChangesAsync();
            }

            return RedirectToPage();
        }
    }
}

```

The *Index.cshtml* file contains the following markup to create an edit link for each contact:

```
<a asp-page="./Edit" asp-route-id="@contact.Id">edit</a>
```

The [Anchor Tag Helper](#) used the `asp-route-{value}` attribute to generate a link to the Edit page. The link contains route data with the contact ID. For example, `http://localhost:5000/Edit/1`.

The *Pages/Edit.cshtml* file:

```

@page "{id:int}"
@model RazorPagesContacts.Pages.EditModel
@addTagHelper *, Microsoft.AspNetCore.Mvc.TagHelpers

 @{
    ViewData["Title"] = "Edit Customer";
}

<h1>Edit Customer - @Model.Customer.Id</h1>
<form method="post">
    <div asp-validation-summary="All"></div>
    <input asp-for="Customer.Id" type="hidden" />
    <div>
        <label asp-for="Customer.Name"></label>
        <div>
            <input asp-for="Customer.Name" />
            <span asp-validation-for="Customer.Name" ></span>
        </div>
    </div>

    <div>
        <button type="submit">Save</button>
    </div>
</form>

```

The first line contains the `@page "{id:int}"` directive. The routing constraint `"{id:int}"` tells the page to accept requests to the page that contain `int` route data. If a request to the page doesn't contain route data that can be converted to an `int`, the runtime returns an HTTP 404 (not found) error. To make the ID optional, append `?` to the route constraint:

```
@page "{id:int?}"
```

The `Pages/Edit.cshtml.cs` file:

```

using System;
using System.Threading.Tasks;
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using Microsoft.EntityFrameworkCore;
using RazorPagesContacts.Data;

namespace RazorPagesContacts.Pages
{
    public class EditModel : PageModel
    {
        private readonly AppDbContext _db;

        public EditModel(AppDbContext db)
        {
            _db = db;
        }

        [BindProperty]
        public Customer Customer { get; set; }

        public async Task<IActionResult> OnGetAsync(int id)
        {
            Customer = await _db.Customers.FindAsync(id);

            if (Customer == null)
            {
                return RedirectToPage("/Index");
            }

            return Page();
        }

        public async Task<IActionResult> OnPostAsync()
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }

            _db.Attach(Customer).State = EntityState.Modified;

            try
            {
                await _db.SaveChangesAsync();
            }
            catch (DbUpdateConcurrencyException)
            {
                throw new Exception($"Customer {Customer.Id} not found!");
            }

            return RedirectToPage("/Index");
        }
    }
}

```

The *Index.cshtml* file also contains markup to create a delete button for each customer contact:

```

<button type="submit" asp-page-handler="delete"
        asp-route-id="@contact.Id">Delete</button>

```

When the delete button is rendered in HTML, its `formaction` includes parameters for:

- The customer contact ID specified by the `asp-route-id` attribute.

- The `handler` specified by the `asp-page-handler` attribute.

Here is an example of a rendered delete button with a customer contact ID of `1`:

```
<button type="submit" formaction="/?id=1&handler=delete">delete</button>
```

When the button is selected, a form `POST` request is sent to the server. By convention, the name of the handler method is selected based the value of the `handler` parameter according to the scheme `OnPost[handler]Async`.

Because the `handler` is `delete` in this example, the `OnPostDeleteAsync` handler method is used to process the `POST` request. If the `asp-page-handler` is set to a different value, such as `remove`, a page handler method with the name `OnPostRemoveAsync` is selected.

```
public async Task<IActionResult> OnPostDeleteAsync(int id)
{
    var contact = await _db.Customers.FindAsync(id);

    if (contact != null)
    {
        _db.Customers.Remove(contact);
        await _db.SaveChangesAsync();
    }

    return RedirectToPage();
}
```

The `OnPostDeleteAsync` method:

- Accepts the `id` from the query string.
- Queries the database for the customer contact with `FindAsync`.
- If the customer contact is found, they're removed from the list of customer contacts. The database is updated.
- Calls `RedirectToPage` to redirect to the root Index page (`/Index`).

## Mark page properties required

Properties on a `PageModel` can be decorated with the `Required` attribute:

```

using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using System.ComponentModel.DataAnnotations;

namespace RazorPagesMovie.Pages.Movies
{
    public class CreateModel : PageModel
    {
        public IActionResult OnGet()
        {
            return Page();
        }

        [BindProperty]
        [Required(ErrorMessage = "Color is required")]
        public string Color { get; set; }

        public IActionResult OnPostAsync()
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }

            // Process color.

            return RedirectToPage("./Index");
        }
    }
}

```

See [Model validation](#) for more information.

## Manage HEAD requests with the OnGet handler

Ordinarily, a HEAD handler is created and called for HEAD requests:

```

public void OnHead()
{
    HttpContext.Response.Headers.Add("HandledBy", "Handled by OnHead!");
}

```

If no HEAD handler (`OnHead`) is defined, Razor Pages falls back to calling the GET page handler (`OnGet`) in ASP.NET Core 2.1 or later. Opt in to this behavior with the [SetCompatibilityVersion method](#) in `Startup.Configure` for ASP.NET Core 2.1 to 2.x:

```

services.AddMvc()
    .SetCompatibilityVersion(Microsoft.AspNetCore.Mvc.CompatibilityVersion.Version_2_1);

```

`SetCompatibilityVersion` effectively sets the Razor Pages option `AllowMappingHeadRequestsToGetHandler` to `true`.

Rather than opting into all 2.1 behaviors with `SetCompatibilityVersion`, you can explicitly opt-in to specific behaviors. The following code opts into the mapping HEAD requests to the GET handler.

```

services.AddMvc()
    .AddRazorPagesOptions(options =>
    {
        options.AllowMappingHeadRequestsToGetHandler = true;
    });

```

# XSRF/CSRF and Razor Pages

You don't have to write any code for [antiforgery validation](#). Antiforgery token generation and validation are automatically included in Razor Pages.

## Using Layouts, partials, templates, and Tag Helpers with Razor Pages

Pages work with all the capabilities of the Razor view engine. Layouts, partials, templates, Tag Helpers, `_ViewStart.cshtml`, `_ViewImports.cshtml` work in the same way they do for conventional Razor views.

Let's declutter this page by taking advantage of some of those capabilities.

Add a [layout page](#) to `Pages/Shared/_Layout.cshtml`:

Add a [layout page](#) to `Pages/_Layout.cshtml`:

```
<!DOCTYPE html>
<html>
<head>
    <title>Razor Pages Sample</title>
</head>
<body>
    <a asp-page="/Index">Home</a>
    @RenderBody()
    <a asp-page="/Customers/Create">Create</a> <br />
</body>
</html>
```

The [Layout](#):

- Controls the layout of each page (unless the page opts out of layout).
- Imports HTML structures such as JavaScript and stylesheets.

See [layout page](#) for more information.

The [Layout](#) property is set in `Pages/_ViewStart.cshtml`:

```
@{
    Layout = "_Layout";
}
```

The layout is in the `Pages/Shared` folder. Pages look for other views (layouts, templates, partials) hierarchically, starting in the same folder as the current page. A layout in the `Pages/Shared` folder can be used from any Razor page under the `Pages` folder.

The layout file should go in the `Pages/Shared` folder.

The layout is in the `Pages` folder. Pages look for other views (layouts, templates, partials) hierarchically, starting in the same folder as the current page. A layout in the `Pages` folder can be used from any Razor page under the `Pages` folder.

We recommend you **not** put the layout file in the `Views/Shared` folder. `Views/Shared` is an MVC views pattern. Razor Pages are meant to rely on folder hierarchy, not path conventions.

View search from a Razor Page includes the `Pages` folder. The layouts, templates, and partials you're using with MVC controllers and conventional Razor views *just work*.

Add a `Pages/_ViewImports.cshtml` file:

```
@namespace RazorPagesContacts.Pages  
@addTagHelper *, Microsoft.AspNetCore.Mvc.TagHelpers
```

`@namespace` is explained later in the tutorial. The `@addTagHelper` directive brings in the [built-in Tag Helpers](#) to all the pages in the *Pages* folder.

When the `@namespace` directive is used explicitly on a page:

```
@page  
@namespace RazorPagesIntro.Pages.Customers  
  
@model NameSpaceModel  
  
<h2>Name space</h2>  
<p>  
    @Model.Message  
</p>
```

The `@page` directive sets the namespace for the page. The `@model` directive doesn't need to include the namespace.

When the `@namespace` directive is contained in `_ViewImports.cshtml`, the specified namespace supplies the prefix for the generated namespace in the Page that imports the `@namespace` directive. The rest of the generated namespace (the suffix portion) is the dot-separated relative path between the folder containing `_ViewImports.cshtml` and the folder containing the page.

For example, the `PageModel` class `Pages/Customers/Edit.cshtml.cs` explicitly sets the namespace:

```
namespace RazorPagesContacts.Pages  
{  
    public class EditModel : PageModel  
    {  
        private readonly AppDbContext _db;  
  
        public EditModel(AppDbContext db)  
        {  
            _db = db;  
        }  
  
        // Code removed for brevity.  
    }  
}
```

The `Pages/_ViewImports.cshtml` file sets the following namespace:

```
@namespace RazorPagesContacts.Pages  
@addTagHelper *, Microsoft.AspNetCore.Mvc.TagHelpers
```

The generated namespace for the `Pages/Customers/Edit.cshtml` Razor Page is the same as the `PageModel` class.

`@namespace` also works with conventional Razor views.

The original `Pages/Create.cshtml` view file:

```

@page
@model RazorPagesContacts.Pages.CreateModel
@addTagHelper *, Microsoft.AspNetCore.Mvc.TagHelpers

<html>
<body>
    <p>
        Enter your name.
    </p>
    <div asp-validation-summary="All"></div>
    <form method="POST">
        <div>Name: <input asp-for="Customer.Name" /></div>
        <input type="submit" />
    </form>
</body>
</html>

```

The updated *Pages/Create.cshtml* view file:

```

@page
@model CreateModel

<html>
<body>
    <p>
        Enter your name.
    </p>
    <div asp-validation-summary="All"></div>
    <form method="POST">
        <div>Name: <input asp-for="Customer.Name" /></div>
        <input type="submit" />
    </form>
</body>
</html>

```

The [Razor Pages starter project](#) contains the *Pages/\_ValidationScriptsPartial.cshtml*, which hooks up client-side validation.

## URL generation for Pages

The `Create` page, shown previously, uses `RedirectToPage`:

```

public async Task<IActionResult> OnPostAsync()
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    _db.Customers.Add(Customer);
    await _db.SaveChangesAsync();
    return RedirectToPage("/Index");
}

```

The app has the following file/folder structure:

- `/Pages`
  - `Index.cshtml`
  - `/Customers`

- *Create.cshtml*
- *Edit.cshtml*
- *Index.cshtml*

The *Pages/Customers/Create.cshtml* and *Pages/Customers/Edit.cshtml* pages redirect to *Pages/Index.cshtml* after success. The string `/Index` is part of the URI to access the preceding page. The string `/Index` can be used to generate URIs to the *Pages/Index.cshtml* page. For example:

- `Url.Page("/Index", ...)`
- `<a asp-page="/Index">My Index Page</a>`
- `RedirectToPage("/Index")`

The page name is the path to the page from the root */Pages* folder including a leading `/` (for example, `/Index`). The preceding URL generation samples offer enhanced options and functional capabilities over hardcoding a URL. URL generation uses [routing](#) and can generate and encode parameters according to how the route is defined in the destination path.

URL generation for pages supports relative names. The following table shows which Index page is selected with different `RedirectToPage` parameters from *Pages/Customers/Create.cshtml*:

REDIRECTTOPAGE(X)	PAGE
<code>RedirectToPage("/Index")</code>	<i>Pages/Index</i>
<code>RedirectToPage("./Index");</code>	<i>Pages/Customers/Index</i>
<code>RedirectToPage("../Index")</code>	<i>Pages/Index</i>
<code>RedirectToPage("Index")</code>	<i>Pages/Customers/Index</i>

`RedirectToPage("Index")`, `RedirectToPage("./Index")`, and `RedirectToPage("../Index")` are *relative names*. The `RedirectToPage` parameter is *combined* with the path of the current page to compute the name of the destination page.

Relative name linking is useful when building sites with a complex structure. If you use relative names to link between pages in a folder, you can rename that folder. All the links still work (because they didn't include the folder name).

## ViewData attribute

Data can be passed to a page with [ViewDataAttribute](#). Properties on controllers or Razor Page models decorated with `[ViewData]` have their values stored and loaded from the [ViewDataDictionary](#).

In the following example, the `AboutModel` contains a `Title` property decorated with `[ViewData]`. The `Title` property is set to the title of the About page:

```
public class AboutModel : PageModel
{
    [ViewData]
    public string Title { get; } = "About";

    public void OnGet()
    {
    }
}
```

In the About page, access the `Title` property as a model property:

```
<h1>@Model.Title</h1>
```

In the layout, the title is read from the ViewData dictionary:

```
<!DOCTYPE html>
<html lang="en">
<head>
<title>@ViewData["Title"] - WebApplication</title>
...

```

## TempData

ASP.NET Core exposes the `TempData` property on a [controller](#). This property stores data until it's read. The `Keep` and `Peek` methods can be used to examine the data without deletion. `TempData` is useful for redirection, when data is needed for more than a single request.

The `[TempData]` attribute is new in ASP.NET Core 2.0 and is supported on controllers and pages.

The following code sets the value of `Message` using `TempData`:

```
public class CreateDotModel : PageModel
{
    private readonly AppDbContext _db;

    public CreateDotModel(AppDbContext db)
    {
        _db = db;
    }

    [TempData]
    public string Message { get; set; }

    [BindProperty]
    public Customer Customer { get; set; }

    public async Task<IActionResult> OnPostAsync()
    {
        if (!ModelState.IsValid)
        {
            return Page();
        }

        _db.Customers.Add(Customer);
        await _db.SaveChangesAsync();
        Message = $"Customer {Customer.Name} added";
        return RedirectToPage("./Index");
    }
}
```

The following markup in the `Pages/Customers/Index.cshtml` file displays the value of `Message` using `TempData`.

```
<h3>Msg: @Model.Message</h3>
```

The `Pages/Customers/Index.cshtml.cs` page model applies the `[TempData]` attribute to the `Message` property.

```
[TempData]  
public string Message { get; set; }
```

See  [TempData](#) for more information.

## Multiple handlers per page

The following page generates markup for two page handlers using the `asp-page-handler` Tag Helper:

```
@page  
@model CreateFATHModel  
  
<html>  
<body>  
    <p>  
        Enter your name.  
    </p>  
    <div asp-validation-summary="All"></div>  
    <form method="POST">  
        <div>Name: <input asp-for="Customer.Name" /></div>  
        <input type="submit" asp-page-handler="JoinList" value="Join" />  
        <input type="submit" asp-page-handler="JoinListUC" value="JOIN UC" />  
    </form>  
</body>  
</html>
```

The form in the preceding example has two submit buttons, each using the `FormActionTagHelper` to submit to a different URL. The `asp-page-handler` attribute is a companion to `asp-page`. `asp-page-handler` generates URLs that submit to each of the handler methods defined by a page. `asp-page` isn't specified because the sample is linking to the current page.

The page model:

```

using System.Threading.Tasks;
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using RazorPagesContacts.Data;

namespace RazorPagesContacts.Pages.Customers
{
    public class CreateFATHModel : PageModel
    {
        private readonly AppDbContext _db;

        public CreateFATHModel(AppDbContext db)
        {
            _db = db;
        }

        [BindProperty]
        public Customer Customer { get; set; }

        public async Task<IActionResult> OnPostJoinListAsync()
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }

            _db.Customers.Add(Customer);
            await _db.SaveChangesAsync();
            return RedirectToPage("/Index");
        }

        public async Task<IActionResult> OnPostJoinListUCAsync()
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }
            Customer.Name = Customer.Name?.ToUpper();
            return await OnPostJoinListAsync();
        }
    }
}

```

The preceding code uses *named handler methods*. Named handler methods are created by taking the text in the name after `On<HTTP Verb>` and before `Async` (if present). In the preceding example, the page methods are `OnPostJoinListAsync` and `OnPostJoinListUCAsync`. With `OnPost` and `Async` removed, the handler names are `JoinList` and `JoinListUC`.

```

<input type="submit" asp-page-handler="JoinList" value="Join" />
<input type="submit" asp-page-handler="JoinListUC" value="JOIN UC" />

```

Using the preceding code, the URL path that submits to `OnPostJoinListAsync` is `http://localhost:5000/Customers/CreateFATH?handler=JoinList`. The URL path that submits to `OnPostJoinListUCAsync` is `http://localhost:5000/Customers/CreateFATH?handler=JoinListUC`.

## Custom routes

Use the `@page` directive to:

- Specify a custom route to a page. For example, the route to the About page can be set to `/Some/Other/Path` with `@page "/Some/Other/Path"`.

- Append segments to a page's default route. For example, an "item" segment can be added to a page's default route with `@page "item"`.
- Append parameters to a page's default route. For example, an ID parameter, `id`, can be required for a page with `@page "{id}"`.

A root-relative path designated by a tilde (`~`) at the beginning of the path is supported. For example, `@page "~/Some/Other/Path"` is the same as `@page "/Some/Other/Path"`.

You can change the query string `?handler=JoinList` in the URL to a route segment `/JoinList` by specifying the route template `@page "{handler?}"`.

If you don't like the query string `?handler=JoinList` in the URL, you can change the route to put the handler name in the path portion of the URL. You can customize the route by adding a route template enclosed in double quotes after the `@page` directive.

```
@page "{handler?}"
@model CreateRouteModel

<html>
<body>
    <p>
        Enter your name.
    </p>
    <div asp-validation-summary="All"></div>
    <form method="POST">
        <div>Name: <input asp-for="Customer.Name" /></div>
        <input type="submit" asp-page-handler="JoinList" value="Join" />
        <input type="submit" asp-page-handler="JoinListUC" value="JOIN UC" />
    </form>
</body>
</html>
```

Using the preceding code, the URL path that submits to `OnPostJoinListAsync` is `http://localhost:5000/Customers/CreateFATH/JoinList`. The URL path that submits to `OnPostJoinListUCAsync` is `http://localhost:5000/Customers/CreateFATH/JoinListUC`.

The `?` following `handler` means the route parameter is optional.

## Configuration and settings

To configure advanced options, use the extension method `AddRazorPagesOptions` on the MVC builder:

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddMvc()
        .AddRazorPagesOptions(options =>
    {
        options.RootDirectory = "/MyPages";
        options.Conventions.AuthorizeFolder("/MyPages/Admin");
    });
}
```

Currently you can use the `RazorPagesOptions` to set the root directory for pages, or add application model conventions for pages. We'll enable more extensibility this way in the future.

To precompile views, see [Razor view compilation](#).

[Download or view sample code](#).

See [Get started with Razor Pages](#), which builds on this introduction.

## Specify that Razor Pages are at the content root

By default, Razor Pages are rooted in the `/Pages` directory. Add [WithRazorPagesAtContentRoot](#) to [AddMvc](#) to specify that your Razor Pages are at the content root ([ContentRootPath](#)) of the app:

```
services.AddMvc()
    .AddRazorPagesOptions(options =>
{
    ...
})
.WithRazorPagesAtContentRoot();
```

## Specify that Razor Pages are at a custom root directory

Add [WithRazorPagesRoot](#) to [AddMvc](#) to specify that your Razor Pages are at a custom root directory in the app (provide a relative path):

```
services.AddMvc()
    .AddRazorPagesOptions(options =>
{
    ...
})
.WithRazorPagesRoot("/path/to/razor/pages");
```

# Create a Web API with ASP.NET Core and Visual Studio for Windows

6/21/2018 • 15 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Mike Wasson](#)

This tutorial builds a web API for managing a list of "to-do" items. A user interface (UI) isn't created.

There are three versions of this tutorial:

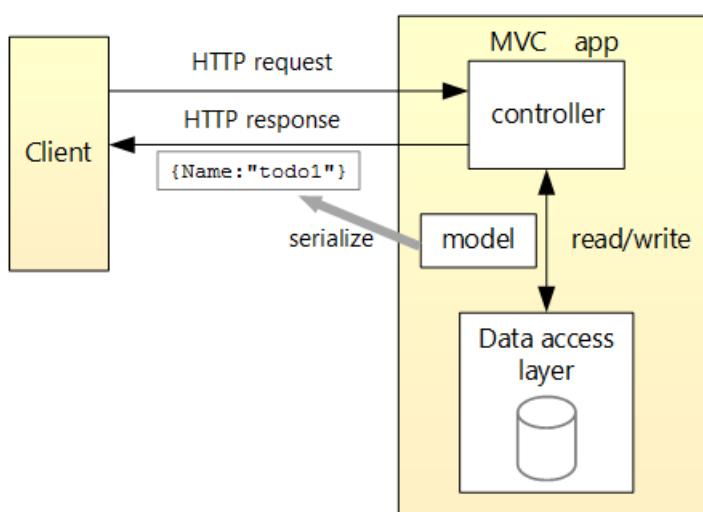

- Windows: Web API with Visual Studio for Windows (This tutorial)
- macOS: [Web API with Visual Studio for Mac](#)
- macOS, Linux, Windows: [Web API with Visual Studio Code](#)

## Overview

This tutorial creates the following API:

API	DESCRIPTION	REQUEST BODY	RESPONSE BODY
GET /api/todo	Get all to-do items	None	Array of to-do items
GET /api/todo/{id}	Get an item by ID	None	To-do item
POST /api/todo	Add a new item	To-do item	To-do item
PUT /api/todo/{id}	Update an existing item	To-do item	None
DELETE /api/todo/{id}	Delete an item	None	None

The following diagram shows the basic design of the app.

- The client is whatever consumes the web API (mobile app, browser, etc.). This tutorial doesn't create a client. [Postman](#) or [curl](#) is used as the client to test the app.
- A *model* is an object that represents the data in the app. In this case, the only model is a to-do item. Models are represented as C# classes, also known as **Plain Old CLR Object** (POCOs).

- A *controller* is an object that handles HTTP requests and creates the HTTP response. This app has a single controller.
- To keep the tutorial simple, the app doesn't use a persistent database. The sample app stores to-do items in an in-memory database.

## Prerequisites

Visual Studio 2017 version 15.7.3 or later with the following workloads:

- **ASP.NET and web development**
- **.NET Core cross-platform development**

.NET Core 2.1 SDK or later

## Create the project

Follow these steps in Visual Studio:

- From the **File** menu, select **New > Project**.
- Select the **ASP.NET Core Web Application** template. Name the project *TodoApi* and click **OK**.
- In the **New ASP.NET Core Web Application - TodoApi** dialog, choose the ASP.NET Core version. Select the **API** template and click **OK**. Do **not** select **Enable Docker Support**.

### Launch the app

In Visual Studio, press CTRL+F5 to launch the app. Visual Studio launches a browser and navigates to `http://localhost:<port>/api/values`, where `<port>` is a randomly chosen port number. Chrome, Microsoft Edge, and Firefox display the following output:

```
["value1","value2"]
```

If using Internet Explorer, you'll be prompted to save a *values.json* file.

### Add a model class

A model is an object representing the data in the app. In this case, the only model is a to-do item.

In Solution Explorer, right-click the project. Select **Add > New Folder**. Name the folder *Models*.

#### NOTE

The model classes can go anywhere in the project. The *Models* folder is used by convention for model classes.

In Solution Explorer, right-click the *Models* folder and select **Add > Class**. Name the class *TodoItem* and click **Add**.

Update the `TodoItem` class with the following code:

```
namespace TodoApi.Models
{
    public class TodoItem
    {
        public long Id { get; set; }
        public string Name { get; set; }
        public bool IsComplete { get; set; }
    }
}
```

The database generates the `Id` when a `TodoItem` is created.

### Create the database context

The *database context* is the main class that coordinates Entity Framework functionality for a given data model. This class is created by deriving from the `Microsoft.EntityFrameworkCore.DbContext` class.

In Solution Explorer, right-click the *Models* folder and select **Add > Class**. Name the class *TodoContext* and click **Add**.

Replace the class with the following code:

```
using Microsoft.EntityFrameworkCore;

namespace TodoApi.Models
{
    public class TodoContext : DbContext
    {
        public TodoContext(DbContextOptions<TodoContext> options)
            : base(options)
        {

        }

        public DbSet<TodoItem> TodoItems { get; set; }
    }
}
```

## Register the database context

In this step, the database context is registered with the [dependency injection](#) container. Services (such as the DB context) that are registered with the dependency injection (DI) container are available to the controllers.

Register the DB context with the service container using the built-in support for [dependency injection](#). Replace the contents of the *Startup.cs* file with the following code:

```
using Microsoft.AspNetCore.Builder;
using Microsoft.AspNetCore.Mvc;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using TodoApi.Models;

namespace TodoApi
{
    public class Startup
    {
        public void ConfigureServices(IServiceCollection services)
        {
            services.AddDbContext<TodoContext>(opt =>
                opt.UseInMemoryDatabase("TodoList"));
            services.AddMvc()
                .SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
        }

        public void Configure(IApplicationBuilder app)
        {
            app.UseMvc();
        }
    }
}
```

```

using Microsoft.AspNetCore.Builder;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using TodoApi.Models;

namespace TodoApi
{
    public class Startup
    {
        public void ConfigureServices(IServiceCollection services)
        {
            services.AddDbContext<TodoContext>(opt =>
                opt.UseInMemoryDatabase("TodoList"));
            services.AddMvc();
        }

        public void Configure(IApplicationBuilder app)
        {
            app.UseMvc();
        }
    }
}

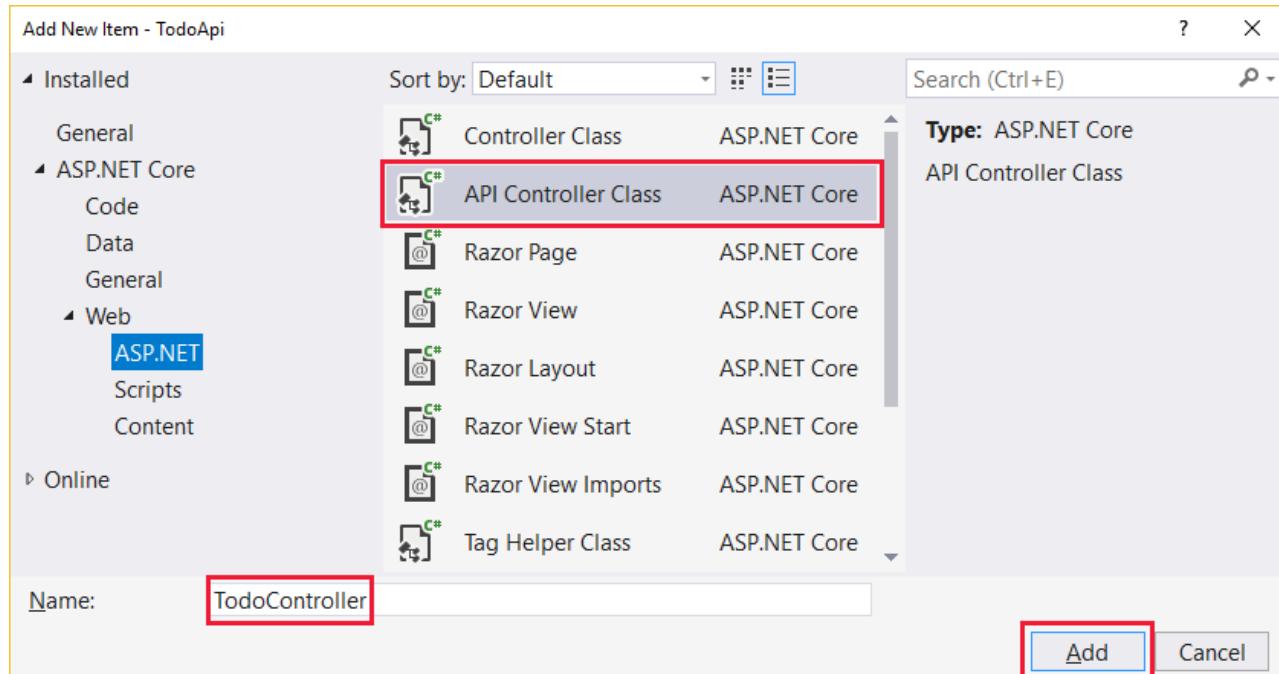

```

The preceding code:

- Removes the unused code.
- Specifies an in-memory database is injected into the service container.

### Add a controller

In Solution Explorer, right-click the *Controllers* folder. Select **Add > New Item**. In the **Add New Item** dialog, select the **API Controller Class** template. Name the class *TodoController*, and click **Add**.

Replace the class with the following code:

```

using Microsoft.AspNetCore.Mvc;
using System.Collections.Generic;
using System.Linq;
using TodoApi.Models;

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

        public TodoController(TodoContext context)
        {
            _context = context;

            if (_context.TodoItems.Count() == 0)
            {
                _context.TodoItems.Add(new TodoItem { Name = "Item1" });
                _context.SaveChanges();
            }
        }
    }
}

```

The preceding code defines an API controller class without methods. In the next sections, methods are added to implement the API.

```

using Microsoft.AspNetCore.Mvc;
using System.Collections.Generic;
using System.Linq;
using TodoApi.Models;

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    [ApiController]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

        public TodoController(TodoContext context)
        {
            _context = context;

            if (_context.TodoItems.Count() == 0)
            {
                _context.TodoItems.Add(new TodoItem { Name = "Item1" });
                _context.SaveChanges();
            }
        }
    }
}

```

The preceding code defines an API controller class without methods. In the next sections, methods are added to implement the API. The class is annotated with an `[ApiController]` attribute to enable some convenient features. For information on features enabled by the attribute, see [Annotate class with ApiControllerAttribute](#).

The controller's constructor uses [Dependency Injection](#) to inject the database context (`TodoContext`) into the controller. The database context is used in each of the [CRUD](#) methods in the controller. The constructor adds an item to the in-memory database if one doesn't exist.

## Get to-do items

To get to-do items, add the following methods to the `TodoController` class:

```
[HttpGet]
public List<TodoItem> GetAll()
{
    return _context.TodoItems.ToList();
}

[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}
```

```
[HttpGet]
public ActionResult<List<TodoItem>> GetAll()
{
    return _context.TodoItems.ToList();
}

[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}
```

These methods implement the two GET methods:

- `GET /api/todo`
- `GET /api/todo/{id}`

Here's a sample HTTP response for the `GetAll` method:

```
[
{
    "id": 1,
    "name": "Item1",
    "isComplete": false
}]
```

Later in the tutorial, I'll show how the HTTP response can be viewed with [Postman](#) or [curl](#).

### Routing and URL paths

The `[HttpGet]` attribute denotes a method that responds to an HTTP GET request. The URL path for each method is constructed as follows:

- Take the template string in the controller's `Route` attribute:

```

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

```

```

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    [ApiController]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

```

- Replace `[controller]` with the name of the controller, which is the controller class name minus the "Controller" suffix. For this sample, the controller class name is **TodoController** and the root name is "todo". ASP.NET Core [routing](#) is case insensitive.
- If the `[HttpGet]` attribute has a route template (such as `[HttpGet("/products")]`), append that to the path. This sample doesn't use a template. For more information, see [Attribute routing with Http\[Verb\] attributes](#).

In the following  `GetById` method, `{id}` is a placeholder variable for the unique identifier of the to-do item. When  `GetById` is invoked, it assigns the value of `{id}` in the URL to the method's `id` parameter.

```

[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}

```

```

[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}

```

`Name = "GetTodo"` creates a named route. Named routes:

- Enable the app to create an HTTP link using the route name.
- Are explained later in the tutorial.

## Return values

The  `GetAll` method returns a collection of `TodoItem` objects. MVC automatically serializes the object to [JSON](#) and writes the JSON into the body of the response message. The response code for this method is 200, assuming there are no unhandled exceptions. Unhandled exceptions are translated into 5xx errors.

In contrast, the  `GetById` method returns the more general [IActionResult type](#), which represents a wide range of

return types.  `GetById` has two different return types:

- If no item matches the requested ID, the method returns a 404 error. Returning `NotFound` returns an HTTP 404 response.
- Otherwise, the method returns 200 with a JSON response body. Returning `Ok` results in an HTTP 200 response.

In contrast, the  `GetById` method returns the `ActionResult<T>` type, which represents a wide range of return types.

`GetById` has two different return types:

- If no item matches the requested ID, the method returns a 404 error. Returning `NotFound` returns an HTTP 404 response.
- Otherwise, the method returns 200 with a JSON response body. Returning `item` results in an HTTP 200 response.

## Launch the app

In Visual Studio, press CTRL+F5 to launch the app. Visual Studio launches a browser and navigates to `http://localhost:<port>/api/values`, where `<port>` is a randomly chosen port number. Navigate to the `Todo` controller at `http://localhost:<port>/api/todo`.

## Implement the other CRUD operations

In the following sections, `Create`, `Update`, and `Delete` methods are added to the controller.

### Create

Add the following `Create` method:

```
[HttpPost]
public IActionResult Create([FromBody] TodoItem item)
{
    if (item == null)
    {
        return BadRequest();
    }

    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}
```

The preceding code is an HTTP POST method, as indicated by the `[HttpPost]` attribute. The `[FromBody]` attribute tells MVC to get the value of the to-do item from the body of the HTTP request.

```
[HttpPost]
public IActionResult Create(TodoItem item)
{
    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}
```

The preceding code is an HTTP POST method, as indicated by the `[HttpPost]` attribute. MVC gets the value of the to-do item from the body of the HTTP request.

The `CreatedAtRoute` method:

- Returns a 201 response. HTTP 201 is the standard response for an HTTP POST method that creates a new

resource on the server.

- Adds a Location header to the response. The Location header specifies the URI of the newly created to-do item. See [10.2.2 201 Created](#).
- Uses the "GetTodo" named route to create the URL. The "GetTodo" named route is defined in  `GetById` :

```
[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}
```

```
[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}
```

### Use Postman to send a Create request

- Start the app.
- Open Postman.

The screenshot shows the Postman application interface. At the top, there's a navigation bar with File, Edit, View, Help, and workspace-related items like My Workspace, IN SYNC, and notifications. Below the header is a toolbar with New, Import, Runner, and other icons. The main area shows a request configuration for a POST method to the URL <https://localhost:44375/api/todo>. The 'Body' tab is selected, indicated by a red box. Under 'Body' type, 'raw' is selected (also highlighted with a red box), and the content type is set to 'JSON (application/json)' (also highlighted with a red box). The request body contains the following JSON:

```
1 [{}  
2   "name": "walk dog",  
3   "isComplete": true  
4 ]
```

Below the request configuration, the Response pane is visible. It shows the status as '201 Created' and the time taken as '148 ms'. The 'Body' tab is selected, and the response body is displayed in JSON format:

```
1 {  
2   "id": 6,  
3   "name": "walk dog",  
4   "isComplete": true  
5 }
```

- Update the port number in the localhost URL.
- Set the HTTP method to *POST*.
- Click the **Body** tab.
- Select the **raw** radio button.
- Set the type to *JSON (application/json)*.
- Enter a request body with a to-do item resembling the following JSON:

```
{  
  "name": "walk dog",  
  "isComplete": true  
}
```

- Click the **Send** button.

#### TIP

If no response displays after clicking **Send**, disable the **SSL certification verification** option. This is found under **File > Settings**. Click the **Send** button again after disabling the setting.

Click the **Headers** tab in the **Response** pane and copy the **Location** header value:

The screenshot shows the Postman application interface. At the top, there's a navigation bar with File, Edit, View, Help, and a workspace dropdown labeled "My Workspace". Below the header are buttons for New, Import, Runner, and a plus sign. To the right of the workspace are icons for sync status ("IN SYNC") and notifications.

The main area shows a request configuration for a POST method to the URL <https://localhost:44375/api/todo>. The "Body" tab is selected, showing a JSON payload:

```
1 [{}  
2   "name": "walk dog",  
3   "isComplete": true  
4 }]
```

Below the body, the "Headers" tab is highlighted with a red box, showing seven headers: Content-Type → application/json; charset=utf-8, Date → Fri, 27 Apr 2018 18:32:32 GMT, and Location → <https://localhost/api/Todo/6>.

The status bar at the bottom indicates Status: 201 Created and Time: 148 ms.

The Location header URI can be used to access the new item.

## Update

Add the following `Update` method:

```
[HttpPut("{id}")]  
public IActionResult Update(long id, [FromBody] TodoItem item)  
{  
    if (item == null || item.Id != id)  
    {  
        return BadRequest();  
    }  
  
    var todo = _context.TodoItems.Find(id);  
    if (todo == null)  
    {  
        return NotFound();  
    }  
  
    todo.IsComplete = item.IsComplete;  
    todo.Name = item.Name;  
  
    _context.TodoItems.Update(todo);  
    _context.SaveChanges();  
    return NoContent();  
}
```

```
[HttpPut("{id}")]
public IActionResult Update(long id, TodoItem item)
{
    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    todo.IsComplete = item.IsComplete;
    todo.Name = item.Name;

    _context.TodoItems.Update(todo);
    _context.SaveChanges();
    return NoContent();
}
```

`Update` is similar to `Create`, except it uses HTTP PUT. The response is [204 \(No Content\)](#). According to the HTTP specification, a PUT request requires the client to send the entire updated entity, not just the deltas. To support partial updates, use HTTP PATCH.

Use Postman to update the to-do item's name to "walk cat":

The screenshot shows the Postman application interface. The request URL is `https://localhost:44375/api/todo/1`. The method is set to `PUT`. The `Body` tab is selected, and the `raw` option is chosen. The JSON payload is:

```
1 {  
2     "name": "walk cat",  
3     "isComplete": true  
4 }
```

The response status is `204 No Content` and the time taken is `70 ms`.

## Delete

Add the following `Delete` method:

```
[HttpDelete("{id}")]
public IActionResult Delete(long id)
{
    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    _context.TodoItems.Remove(todo);
    _context.SaveChanges();
    return NoContent();
}
```

The `Delete` response is [204 \(No Content\)](#).

Use Postman to delete the to-do item:

The screenshot shows the Postman application window. At the top, there are tabs for File, Edit, View, and Help. Below the tabs are buttons for New, Import, Runner, and a workspace dropdown labeled "My Workspace". To the right of the workspace dropdown are icons for IN SYNC, environment management, and notifications. The main toolbar has three tabs: "DELETE" (highlighted with a red box), "https://localhost:44375/api/todo/1" (the URL being tested), and "Params". On the far right of the toolbar is a "Send" button. Below the toolbar, there are tabs for Authorization, Headers, Body, Pre-request Script, and Tests. The Authorization tab is selected and shows "No Auth" selected from a dropdown. A note states: "The authorization header will be automatically generated when you send the request. [Learn more about authorization](#)". To the right of this note, it says: "This request does not use any authorization. [Learn more about authorization](#)". The Body tab is selected at the bottom, showing a "Pretty" button, "Raw" button, "Preview" button, and a "Text" dropdown set to "Text". Below these buttons is a text area containing the number "1". At the very bottom of the interface are several small icons: a file icon, a search icon, a refresh icon, a "BUILD" dropdown, and a lightbulb icon.

## Call the Web API with jQuery

In this section, an HTML page is added that uses jQuery to call the Web API. jQuery initiates the request and updates the page with the details from the API's response.

Configure the project to serve static files and to enable default file mapping. This is accomplished by invoking the `UseStaticFiles` and `UseDefaultFiles` extension methods in `Startup.Configure`. For more information, see [Static files](#).

```

public void Configure(IApplicationBuilder app)
{
    app.UseDefaultFiles();
    app.UseStaticFiles();
    app.UseMvc();
}

```

Add an HTML file, named *index.html*, to the project's *wwwroot* directory. Replace its contents with the following markup:

```

<!DOCTYPE html>
<html>
<head>
    <meta charset="UTF-8">
    <title>To-do CRUD</title>
    <style>
        input[type='submit'], button, [aria-label] {
            cursor: pointer;
        }

        #spoiler {
            display: none;
        }

        table {
            font-family: Arial, sans-serif;
            border: 1px solid;
            border-collapse: collapse;
        }

        th {
            background-color: #0066CC;
            color: white;
        }

        td {
            border: 1px solid;
            padding: 5px;
        }
    </style>
</head>
<body>
    <h1>To-do CRUD</h1>
    <h3>Add</h3>
    <form action="javascript:void(0);" method="POST" onsubmit="addItem()">
        <input type="text" id="add-name" placeholder="New to-do">
        <input type="submit" value="Add">
    </form>

    <div id="spoiler">
        <h3>Edit</h3>
        <form class="my-form">
            <input type="hidden" id="edit-id">
            <input type="checkbox" id="edit-isComplete">
            <input type="text" id="edit-name">
            <input type="submit" value="Edit">
            <a onclick="closeInput()" aria-label="Close">✖</a>
        </form>
    </div>

    <p id="counter"></p>

    <table>
        <tr>
            <th>Is Complete</th>
            <th>Name</th>

```

```

        <th></th>
        <th></th>
    </tr>
    <tbody id="todos"></tbody>
</table>

<script src="https://code.jquery.com/jquery-3.3.1.min.js"
        integrity="sha256-FgpCb/KJQ1LNfOu91ta32o/NMZxltwRo8QtmkMRdAu8="
        crossorigin="anonymous"></script>
<script src="site.js"></script>
</body>
</html>

```

Add a JavaScript file, named *site.js*, to the project's *wwwroot* directory. Replace its contents with the following code:

```

const uri = 'api/todo';
let todos = null;
function getCount(data) {
    const el = $('#counter');
    let name = 'to-do';
    if (data) {
        if (data > 1) {
            name = 'to-dos';
        }
        el.text(data + ' ' + name);
    } else {
        el.html('No ' + name);
    }
}

$(document).ready(function () {
    getData();
});

function getData() {
    $.ajax({
        type: 'GET',
        url: uri,
        success: function (data) {
            $('#todos').empty();
            getCount(data.length);
            $.each(data, function (key, item) {
                const checked = item.isComplete ? 'checked' : '';

                $('<tr><td><input disabled="true" type="checkbox" ' + checked + '></td>' +
                    '<td>' + item.name + '</td>' +
                    '<td><button onclick="editItem(' + item.id + ')">Edit</button></td>' +
                    '<td><button onclick="deleteItem(' + item.id + ')">Delete</button></td>' +
                    '</tr>').appendTo($('#todos'));
            });
            todos = data;
        }
    });
}

function addItem() {
    const item = {
        'name': $('#add-name').val(),
        'isComplete': false
    };

    $.ajax({
        type: 'POST',
        accepts: 'application/json',
        url: uri,
        contentType: 'application/json',

```

```

        },
        data: JSON.stringify(item),
        error: function (jqXHR, textStatus, errorThrown) {
            alert('here');
        },
        success: function (result) {
            getData();
            $('#add-name').val('');
        }
    });
}

function deleteItem(id) {
    $.ajax({
        url: uri + '/' + id,
        type: 'DELETE',
        success: function (result) {
            getData();
        }
    });
}

function editItem(id) {
    $.each(todos, function (key, item) {
        if (item.id === id) {
            $('#edit-name').val(item.name);
            $('#edit-id').val(item.id);
            $('#edit-isComplete').val(item.isComplete);
        }
    });
    $('#spoiler').css({ 'display': 'block' });
}

$('.my-form').on('submit', function () {
    const item = {
        'name': $('#edit-name').val(),
        'isComplete': $('#edit-isComplete').is(':checked'),
        'id': $('#edit-id').val()
    };

    $.ajax({
        url: uri + '/' + $('#edit-id').val(),
        type: 'PUT',
        accepts: 'application/json',
        contentType: 'application/json',
        data: JSON.stringify(item),
        success: function (result) {
            getData();
        }
    });

    closeInput();
    return false;
});

function closeInput() {
    $('#spoiler').css({ 'display': 'none' });
}

```

A change to the ASP.NET Core project's launch settings may be required to test the HTML page locally. Open `launchSettings.json` in the `Properties` directory of the project. Remove the `launchUrl` property to force the app to open at `index.html`—the project's default file.

There are several ways to get jQuery. In the preceding snippet, the library is loaded from a CDN. This sample is a complete CRUD example of calling the API with jQuery. There are additional features in this sample to make the experience richer. Below are explanations around the calls to the API.

## Get a list of to-do items

To get a list of to-do items, send an HTTP GET request to `/api/todo`.

The jQuery `ajax` function sends an AJAX request to the API, which returns JSON representing an object or array. This function can handle all forms of HTTP interaction, sending an HTTP request to the specified `url`. `GET` is used as the `type`. The `success` callback function is invoked if the request succeeds. In the callback, the DOM is updated with the to-do information.

```
$(document).ready(function () {
    getData();
});

function getData() {
    $.ajax({
        type: 'GET',
        url: uri,
        success: function (data) {
            $('#todos').empty();
            getCount(data.length);
            $.each(data, function (key, item) {
                const checked = item.isComplete ? 'checked' : '';

                $('<tr><td><input disabled="true" type="checkbox" ' + checked + '></td>' +
                    '<td>' + item.name + '</td>' +
                    '<td><button onclick="editItem(' + item.id + ')">Edit</button></td>' +
                    '<td><button onclick="deleteItem(' + item.id + ')">Delete</button></td>' +
                    '</tr>').appendTo($('#todos'));
            });
            todos = data;
        }
    });
}
```

## Add a to-do item

To add a to-do item, send an HTTP POST request to `/api/todo/`. The request body should contain a to-do object. The `ajax` function is using `POST` to call the API. For `POST` and `PUT` requests, the request body represents the data sent to the API. The API is expecting a JSON request body. The `accepts` and `contentType` options are set to `application/json` to classify the media type being received and sent, respectively. The data is converted to a JSON object using `JSON.stringify`. When the API returns a successful status code, the `getData` function is invoked to update the HTML table.

```

function addItem() {
    const item = {
        'name': $('#add-name').val(),
        'isComplete': false
    };

    $.ajax({
        type: 'POST',
        accepts: 'application/json',
        url: uri,
        contentType: 'application/json',
        data: JSON.stringify(item),
        error: function (jqXHR, textStatus, errorThrown) {
            alert('here');
        },
        success: function (result) {
            getData();
            $('#add-name').val('');
        }
    });
}

```

## Update a to-do item

Updating a to-do item is very similar to adding one, since both rely on a request body. The only real difference between the two in this case is that the `url` changes to add the unique identifier of the item, and the `type` is `PUT`.

```

$.ajax({
    url: uri + '/' + $('#edit-id').val(),
    type: 'PUT',
    accepts: 'application/json',
    contentType: 'application/json',
    data: JSON.stringify(item),
    success: function (result) {
        getData();
    }
});

```

## Delete a to-do item

Deleting a to-do item is accomplished by setting the `type` on the AJAX call to `DELETE` and specifying the item's unique identifier in the URL.

```

$.ajax({
    url: uri + '/' + id,
    type: 'DELETE',
    success: function (result) {
        getData();
    }
});

```

## Next steps

- For information on using a persistent database, see:

## Host and deploy

- [Deploy an ASP.NET Core web app to Azure using Visual Studio](#)
- [Deploy an ASP.NET Core web app to Azure using the command line](#)
- [Publish to an Azure Web App with continuous deployment](#)
- [Deploy an ASP.NET container to a remote Docker host](#)
- [ASP.NET Core and Azure Service Fabric](#)

## How to download a sample

1. [Download the ASP.NET repository zip file.](#)
2. Unzip the *Docs-master.zip* file.
3. Use the URL in the sample link to help you navigate to the sample directory.

# Create a Razor Pages web app with ASP.NET Core

7/11/2018 • 2 minutes to read • [Edit Online](#)

This series explains the basics of building a Razor Pages web app with ASP.NET Core using Visual Studio. Other versions of this series include a [macOS version](#) and a [Visual Studio Code version](#).

1. [Get started with Razor Pages](#)
2. [Add a model to a Razor Pages app](#)
3. [Scaffolded Razor Pages](#)
4. [Work with SQL Server LocalDB](#)
5. [Updating the pages](#)
6. [Add search](#)
7. [Add a new field](#)
8. [Add validation](#)

After the tutorial to add a file upload capability to the sample app, see [Upload files to a Razor Page in ASP.NET Core](#).

# Get started with Razor Pages in ASP.NET Core

7/3/2018 • 6 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

We recommend you follow the ASP.NET Core 2.1 version of this tutorial. It's **much** easier to follow and covers more features. Select **ASP.NET Core 2.1** in the version selector.

The screenshot shows a dropdown menu with a red border around the title 'ASP.NET Core 2.0'. Below it is a search bar labeled 'Filter by title'. The menu items are:

- Introduction
- Get started
- Tutorials
  - Create a Razor Pages web app
- [Get started with Razor Pages](#) (This item is highlighted with a blue background)
- Add a model
- Scaffolded Razor Pages

This tutorial teaches the basics of building an ASP.NET Core Razor Pages web app. Razor Pages is the recommended way to build UI for web apps in ASP.NET Core.

There are three versions of this tutorial:

- Windows: This tutorial
- MacOS: [Get started with Razor Pages with Visual Studio for Mac](#)
- macOS, Linux, and Windows: [Get started with ASP.NET Core Razor Pages in Visual Studio Code](#)

[View or download sample code \(how to download\)](#)

## Prerequisites

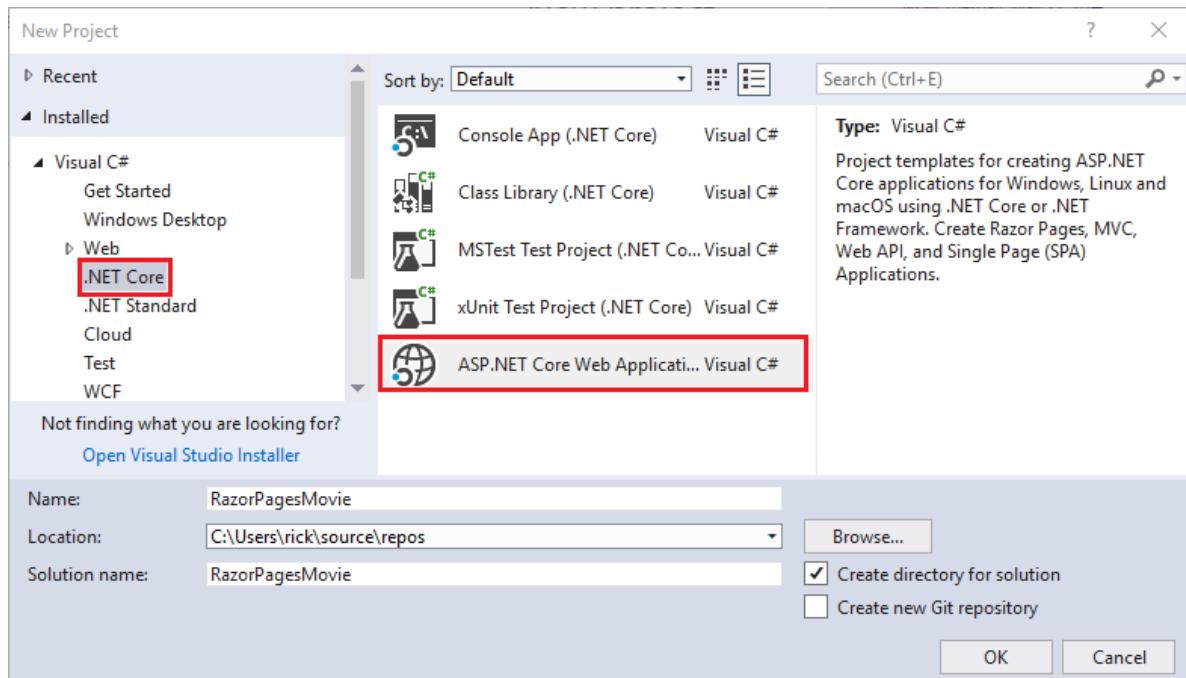

[Visual Studio 2017 version 15.7.3 or later](#) with the following workloads:

- **ASP.NET and web development**
- **.NET Core cross-platform development**

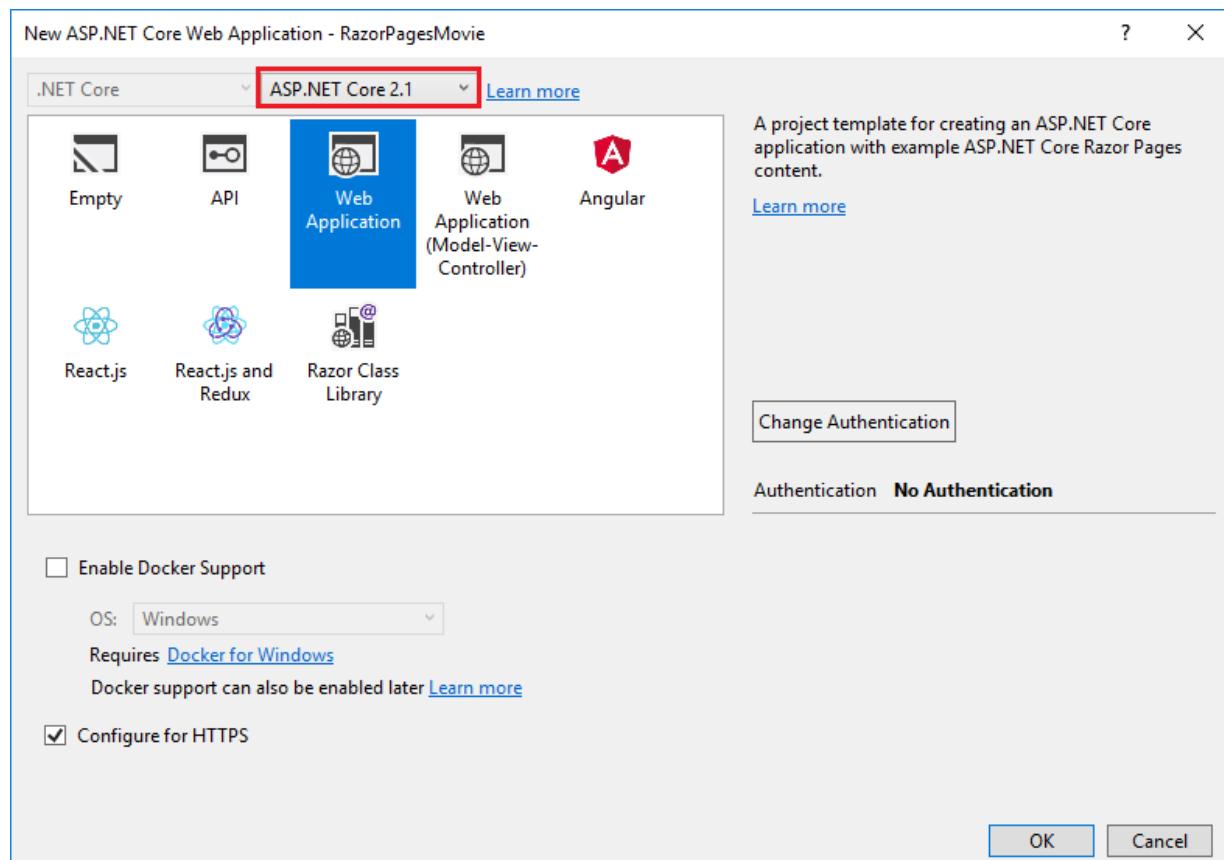

[.NET Core 2.1 SDK or later](#)

## Create a Razor web app

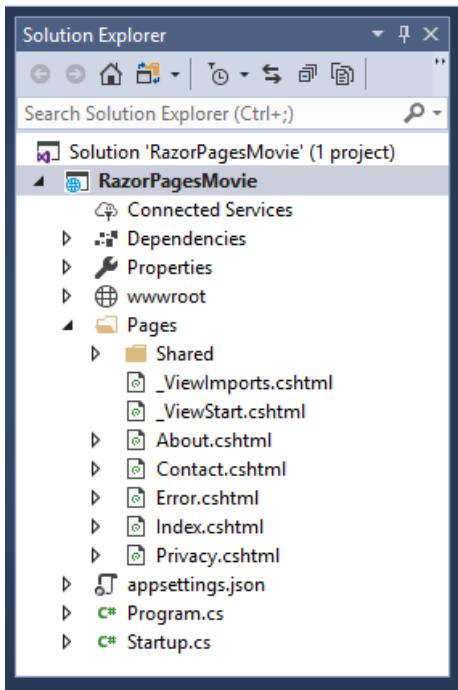

- From the Visual Studio **File** menu, select **New > Project**.
- Create a new ASP.NET Core Web Application. Name the project **RazorPagesMovie**. It's important to name the project *RazorPagesMovie* so the namespaces will match when you copy/paste code.

- Select **ASP.NET Core 2.1** in the dropdown, and then select **Web Application**.

The Visual Studio template creates a starter project:

Press **F5** to run the app in debug mode or **Ctrl-F5** to run without attaching the debugger. Select **Accept** to consent to tracking. This app doesn't track personal information. The template generated code includes assets to help meet [General Data Protection Regulation \(GDPR\)](#).

The screenshot shows a web browser window displaying the 'Home page - RazorPages' page. The URL is https://localhost:44353. A tracking consent dialog is present at the top right of the page, containing the text 'Use this space to summarize your privacy and cookie use policy.' with a 'Learn More' link, and a red box highlights the 'Accept' button.

ASP.NET Core | Windows Linux OSX

Learn how to build ASP.NET apps that can run anywhere. [Learn More](#)

● ○ ○

## Application uses

- Sample pages using ASP.NET Core Razor Pages
- Theming using [Bootstrap](#)

## How to

The following image shows the app after accepting tracking:

RazorPagesMovie Home About Contact

ASP.NET Core | Windows | Linux | OSX

Learn how to build ASP.NET apps that can run anywhere. [Learn More](#)

● ○ ○

## Application uses

- Sample pages using ASP.NET Core Razor Pages
- Theming using Bootstrap

## How to

- Working with Razor Pages.
- Manage User Secrets using Secret Manager.

- Visual Studio starts **IIS Express** and runs the app. The address bar shows `localhost:port#` and not something like `example.com`. That's because `localhost` is the standard hostname for your local computer. Localhost only serves web requests from the local computer. When Visual Studio creates a web project, a random port is used for the web server. In the preceding image, the port number is 5000. When you run the app, you'll see a different port number.
- Launching the app with **Ctrl+F5** (non-debug mode) allows you to make code changes, save the file, refresh the browser, and see the code changes. Many developers prefer to use non-debug mode to quickly launch the app and view changes.

The default template creates **RazorPagesMovie**, **Home**, **About** and **Contact** links and pages. Depending on the size of your browser window, you might need to click the navigation icon to show the links.

## Application uses

- Sample pages using ASP.NET Core Razor Pages
- [Bower](#) for managing client-side libraries
- Theming using [Bootstrap](#)

## How to

- [Working with Razor Pages](#).
- [Manage User Secrets using Secret Manager](#).
- [Use logging to log a message](#).
- [Add packages using NuGet](#).

Test the links. The **RazorPagesMovie** and **Home** links go to the Index page. The **About** and **Contact** links go to the [About](#) and [Contact](#) pages, respectively.

## Project files and folders

The following table lists the files and folders in the project. For this tutorial, the *Startup.cs* file is the most important to understand. You don't need to review each link provided below. The links are provided as a reference when you need more information on a file or folder in the project.

FILE OR FOLDER	PURPOSE
<code>wwwroot</code>	Contains static assets. See <a href="#">Static files</a> .
<code>Pages</code>	Folder for <a href="#">Razor Pages</a> .
<code>appsettings.json</code>	<a href="#">Configuration</a>
<code>Program.cs</code>	Configures the <a href="#">host</a> of the ASP.NET Core app.
<code>Startup.cs</code>	Configures services and the request pipeline. See <a href="#">Startup</a> .

### The Pages/Shared folder

The `_Layout.cshtml` file contains common HTML elements (script and stylesheet links) and sets the layout for the app. For example when you select **RazorPagesMovie**, **Home**, **About** or **Contact**, a common set of elements appears in the webpage. The common elements include the navigation menu at the top and the header at the bottom of the window. For more information, see [Layout](#).

The `_ValidationScriptsPartial.cshtml` file provides a reference to [jQuery](#) validation scripts. When the [Create](#)

and [Edit](#) pages are added later in the tutorial, the `_ValidationScriptsPartial.cshtml` file is used.

The `_CookieConsentPartial.cshtml` file provides a navigation bar and content to summarize the privacy and cookie use policy. For more information on the GDPR assets included in the project, see [EU General Data Protection Regulation \(GDPR\) support in ASP.NET Core](#).

## The Pages folder

The `_ViewStart.cshtml` sets the Razor Pages `Layout` property to use the `_Layout.cshtml` file. See [Layout](#) for more information.

The `_ViewImports.cshtml` file contains Razor directives that are imported into each Razor Page. See [Importing Shared Directives](#) for more information.

The `About`, `Contact` and `Index` pages are basic pages you can use to start an app. The `Error` page is used to display error information.

## Prerequisites

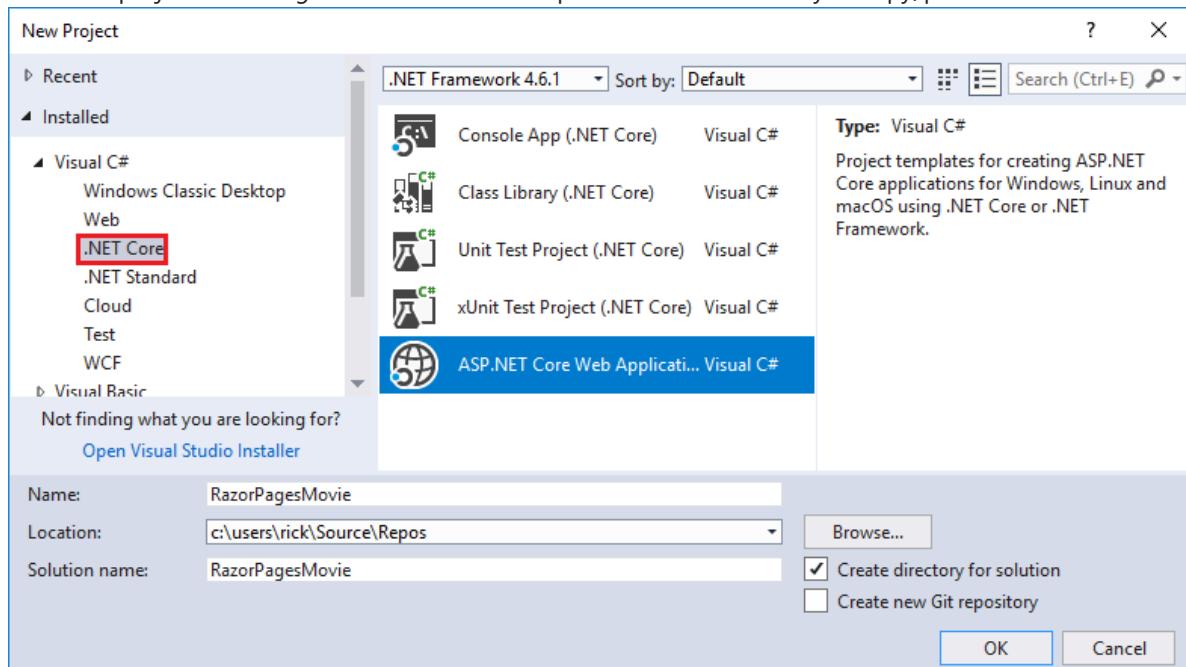

Visual Studio 2017 version 15.7.3 or later with the following workloads:

- **ASP.NET and web development**
- **.NET Core cross-platform development**

.NET Core 2.1 SDK or later

## Create a Razor web app

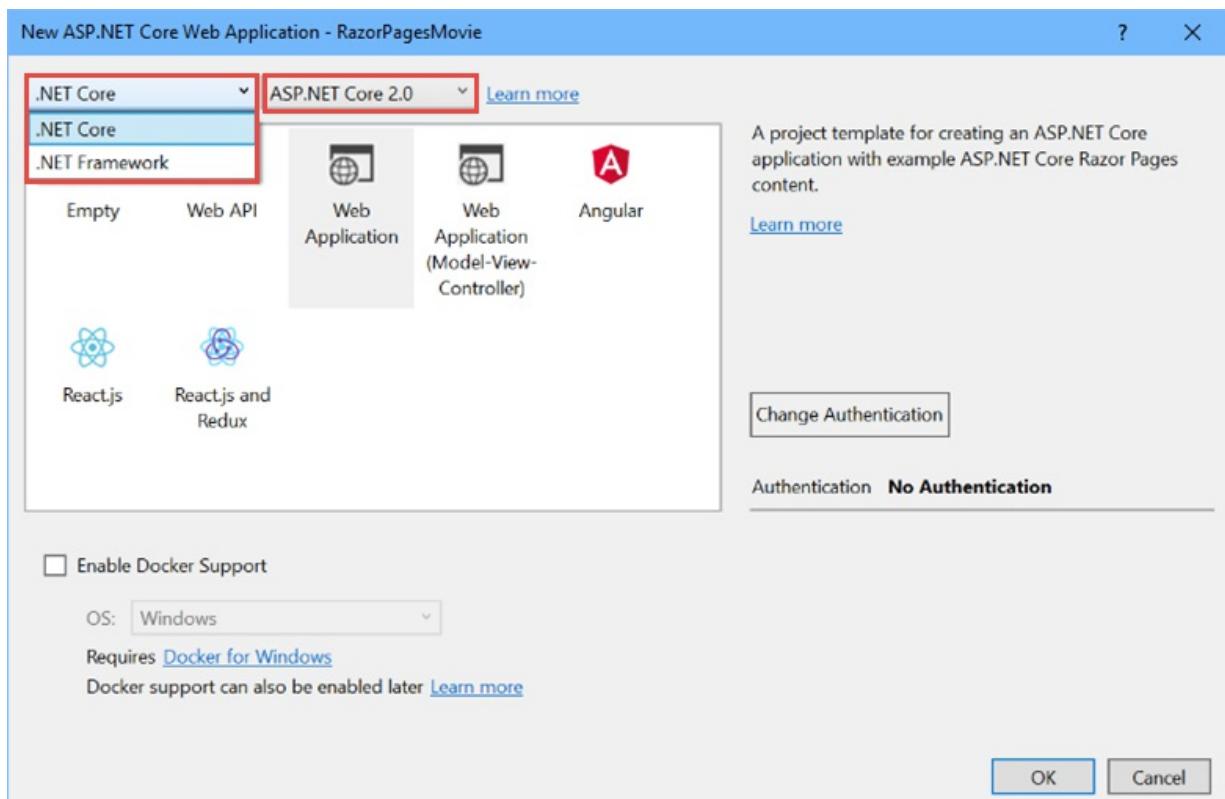

- From the Visual Studio **File** menu, select **New > Project**.
- Create a new ASP.NET Core Web Application. Name the project **RazorPagesMovie**. It's important to name the project *RazorPagesMovie* so the namespaces will match when you copy/paste code.

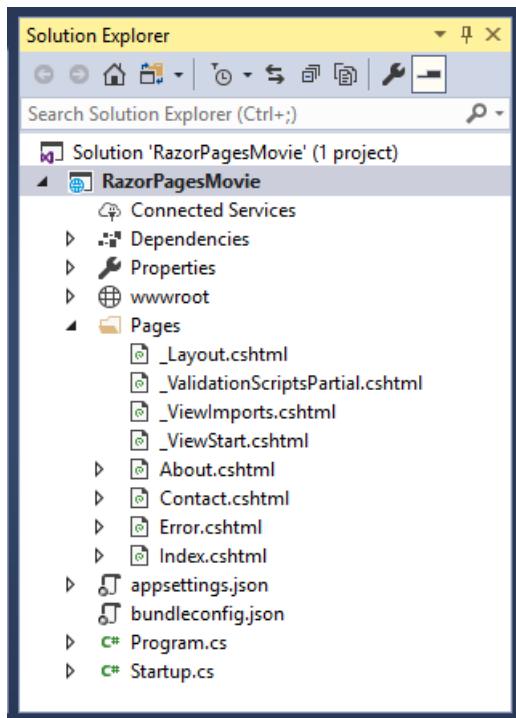

- Select **ASP.NET Core 2.0** in the dropdown, and then select **Web Application**.

### NOTE

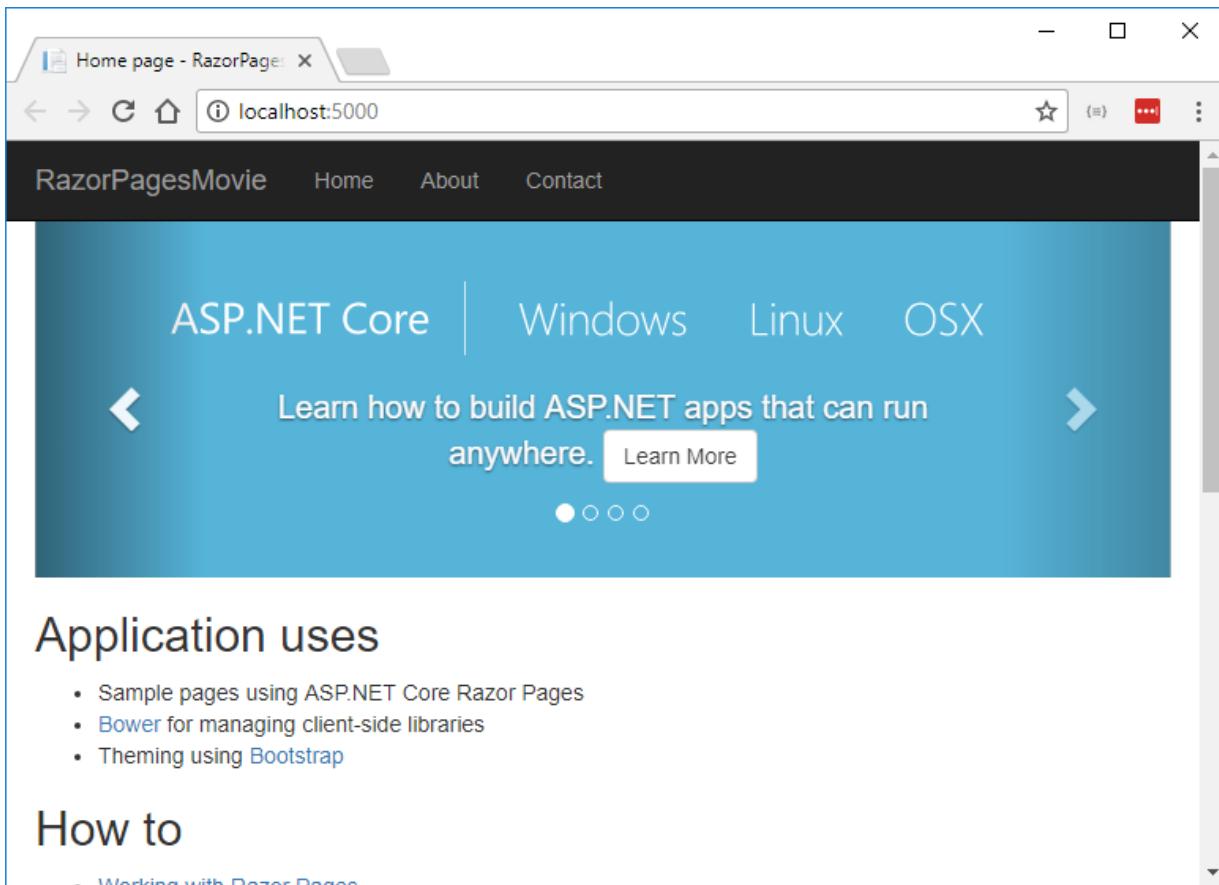

To use ASP.NET Core with .NET Framework, you must first select **.NET Framework** from the leftmost drop-down in the dialog, then you can select the desired ASP.NET Core version.

The Visual Studio template creates a starter project:

Press **F5** to run the app in debug mode or **Ctrl-F5** to run without attaching the debugger

## Application uses

- Sample pages using ASP.NET Core Razor Pages
- Bower for managing client-side libraries
- Theming using Bootstrap

## How to

Working with Razor Pages

- Visual Studio starts IIS Express and runs your app. The address bar shows `localhost:port#` and not something like `example.com`. That's because `localhost` is the standard hostname for your local computer. Localhost only serves web requests from the local computer. When Visual Studio creates a web project, a random port is used for the web server. In the preceding image, the port number is 5000. When you run the app, you'll see a different port number.
- Launching the app with **Ctrl+F5** (non-debug mode) allows you to make code changes, save the file, refresh the browser, and see the code changes. Many developers prefer to use non-debug mode to quickly launch the app and view changes.

The default template creates **RazorPagesMovie**, **Home**, **About** and **Contact** links and pages. Depending on the size of your browser window, you might need to click the navigation icon to show the links.

## Application uses

- Sample pages using ASP.NET Core Razor Pages
- [Bower](#) for managing client-side libraries
- Theming using [Bootstrap](#)

## How to

- [Working with Razor Pages](#).
- [Manage User Secrets using Secret Manager](#).
- [Use logging to log a message](#).
- [Add packages using NuGet](#).

Test the links. The **RazorPagesMovie** and **Home** links go to the Index page. The **About** and **Contact** links go to the [About](#) and [Contact](#) pages, respectively.

## Project files and folders

The following table lists the files and folders in the project. For this tutorial, the *Startup.cs* file is the most important to understand. You don't need to review each link provided below. The links are provided as a reference when you need more information on a file or folder in the project.

FILE OR FOLDER	PURPOSE
wwwroot	Contains static files. See <a href="#">Static files</a> .
Pages	Folder for <a href="#">Razor Pages</a> .
<i>appsettings.json</i>	<a href="#">Configuration</a>
<i>Program.cs</i>	<a href="#">Hosts</a> the ASP.NET Core app.
<i>Startup.cs</i>	Configures services and the request pipeline. See <a href="#">Startup</a> .

### The Pages folder

The *\_Layout.cshtml* file contains common HTML elements (scripts and stylesheets) and sets the layout for the application. For example, when you click on **RazorPagesMovie**, **Home**, **About** or **Contact**, you see the same elements. The common elements include the navigation menu on the top and the header on the bottom of the window. See [Layout](#) for more information.

The *\_ViewStart.cshtml* sets the Razor Pages [Layout](#) property to use the *\_Layout.cshtml* file. See [Layout](#) for

more information.

The `_ViewImports.cshtml` file contains Razor directives that are imported into each Razor Page. See [Importing Shared Directives](#) for more information.

The `_ValidationScriptsPartial.cshtml` file provides a reference to [jQuery](#) validation scripts. When we add `Create` and `Edit` pages later in the tutorial, the `_ValidationScriptsPartial.cshtml` file will be used.

The `About`, `Contact` and `Index` pages are basic pages you can use to start an app. The `Error` page is used to display error information.

NEXT: ADDING A  
MODEL

# Add a model to a Razor Pages app in ASP.NET Core

7/10/2018 • 8 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section, you add classes for managing movies in a database. You use these classes with [Entity Framework Core](#) (EF Core) to work with a database. EF Core is an object-relational mapping (ORM) framework that simplifies the data access code that you have to write.

The model classes you create are known as POCO classes (from "plain-old CLR objects") because they don't have any dependency on EF Core. They define the properties of the data that are stored in the database.

In this tutorial, you write the model classes first, and EF Core creates the database. An alternate approach not covered here is to [generate model classes from an existing database](#).

[View or download](#) sample.

## Add a data model

In Solution Explorer, right-click the **RazorPagesMovie** project > **Add > New Folder**. Name the folder *Models*.

Right click the *Models* folder. Select **Add > Class**. Name the class **Movie** and add the following properties:

Replace the contents of the `Movie` class with the following code:

```
using System;
using System.ComponentModel.DataAnnotations.Schema;

namespace RazorPagesMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

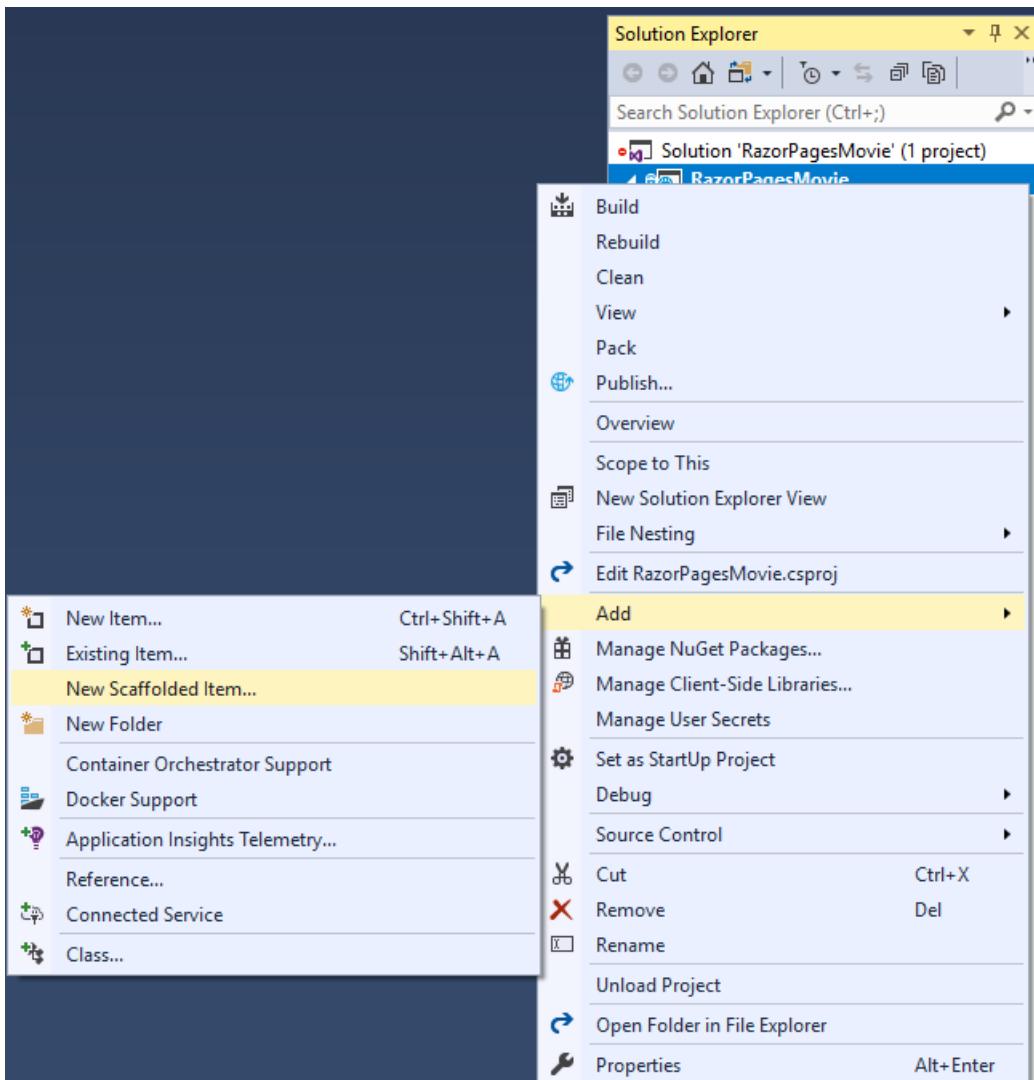

## Scaffold the movie model

In this section, the movie model is scaffolded. That is, the scaffolding tool produces pages for Create, Read, Update, and Delete (CRUD) operations for the movie model.

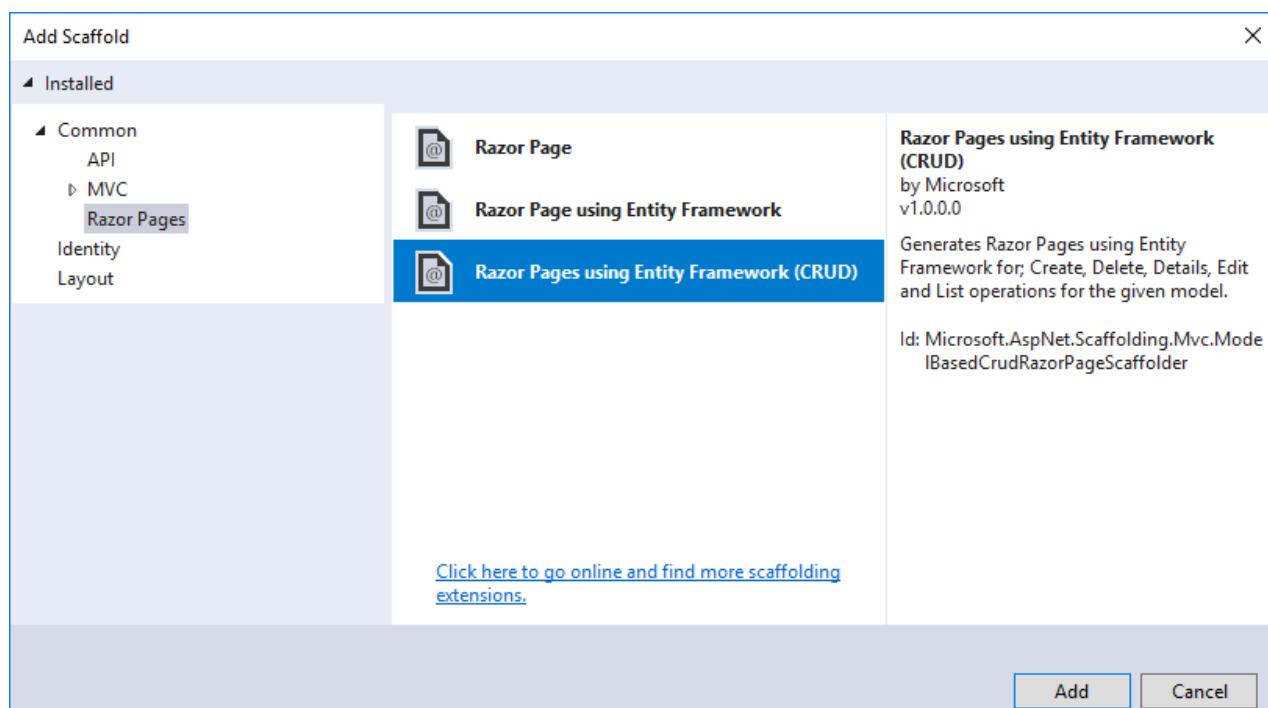

Create a *Pages/Movies* folder:

- In **Solution Explorer**, right click on the *Pages* folder > **Add > New Folder**.
- Name the folder *Movies*

In **Solution Explorer**, right click on the *Pages/Movies* folder > **Add > New Scaffolded Item**.

In the **Add Scaffold** dialog, select **Razor Pages using Entity Framework (CRUD) > ADD**.

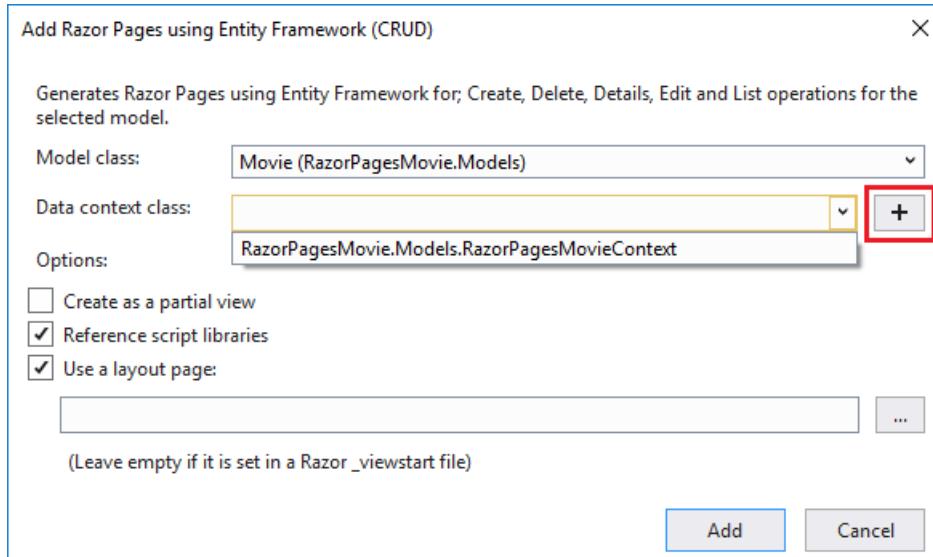

Complete the **Add Razor Pages using Entity Framework (CRUD)** dialog:

- In the **Model class** drop down, select **Movie (RazorPagesMovie.Models)**.
- In the **Data context class** row, select the + (plus) sign and accept the generated name

## RazorPagesMovie.Models.RazorPagesMovieContext.

- In the **Data context class** drop down, select **RazorPagesMovie.Models.RazorPagesMovieContext**
- Select **Add**.

The scaffold process created and changed the following files:

### Files created

- *Pages/Movies* Create, Delete, Details, Edit, Index. These pages are detailed in the next tutorial.
- *Data/RazorPagesMovieContext.cs*

### Files updates

- *Startup.cs*: Changes to this file are detailed in the next section.
- *appsettings.json*: The connection string used to connect to a local database is added.

## Examine the context registered with dependency injection

ASP.NET Core is built with [dependency injection](#). Services (such as the EF Core DB context) are registered with dependency injection during application startup. Components that require these services (such as Razor Pages) are provided these services via constructor parameters. The constructor code that gets a DB context instance is shown later in the tutorial.

The scaffolding tool automatically created a DB context and registered it with the dependency injection container.

Examine the `Startup.ConfigureServices` method. The highlighted line was added by the scaffolder:

```
public void ConfigureServices(IServiceCollection services)
{
    services.Configure<CookiePolicyOptions>(options =>
    {
        options.CheckConsentNeeded = context => true;
        options.MinimumSameSitePolicy = SameSiteMode.None;
    });

    services.AddMvc().SetCompatibilityVersion(CompatibilityVersion.Version_2_1);

    services.AddDbContext<RazorPagesMovieContext>(options =>
        options.UseSqlServer(Configuration.GetConnectionString("RazorPagesMovieContext")));
}
```

The main class that coordinates EF Core functionality for a given data model is the DB context class. The data

context is derived from [Microsoft.EntityFrameworkCore.DbContext](#). The data context specifies which entities are included in the data model. In this project, the class is named `RazorPagesMovieContext`.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Threading.Tasks;
using Microsoft.EntityFrameworkCore;

namespace RazorPagesMovie.Models
{
    public class RazorPagesMovieContext : DbContext
    {
        public RazorPagesMovieContext (DbContextOptions<RazorPagesMovieContext> options)
            : base(options)
        {

        }

        public DbSet<RazorPagesMovie.Models.Movie> Movie { get; set; }
    }
}
```

The preceding code creates a `DbSet<Movie>` property for the entity set. In Entity Framework terminology, an entity set typically corresponds to a database table. An entity corresponds to a row in the table.

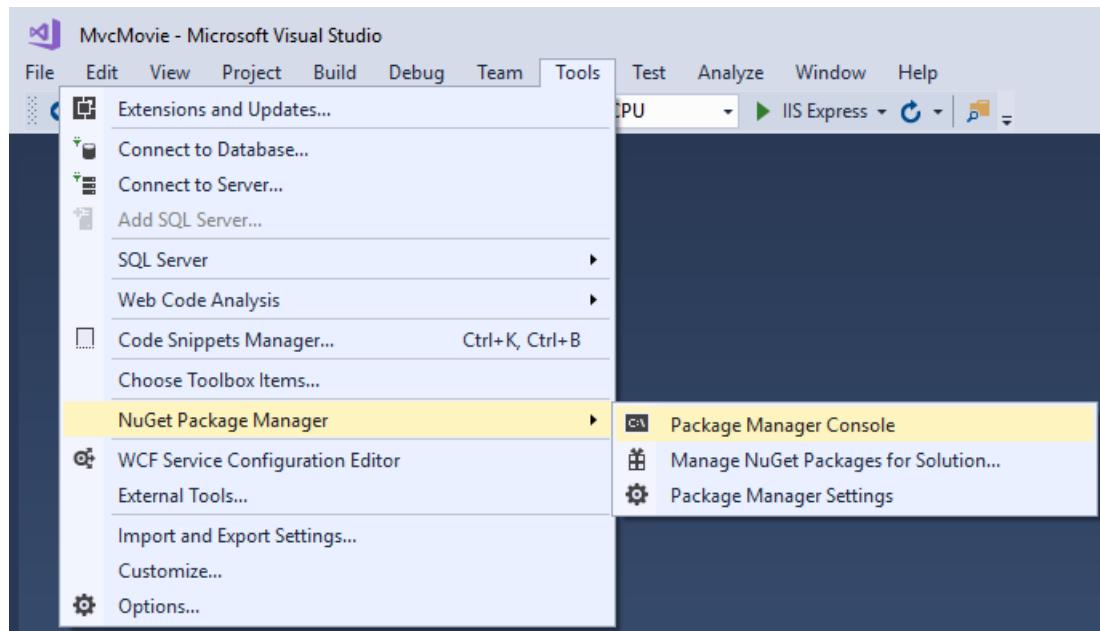

The name of the connection string is passed in to the context by calling a method on a `DbContextOptions` object. For local development, the [ASP.NET Core configuration system](#) reads the connection string from the `appsettings.json` file.

## Perform initial migration

In this section, you use the Package Manager Console (PMC) to:

- Add an initial migration.
- Update the database with the initial migration.

From the **Tools** menu, select **NuGet Package Manager > Package Manager Console**.

In the PMC, enter the following commands:

```
Add-Migration Initial  
Update-Database
```

Alternatively, the following .NET Core CLI commands can be used:

```
dotnet ef migrations add Initial  
dotnet ef database update
```

Ignore the following warning message, you fix that in the next tutorial:

```
Microsoft.EntityFrameworkCore.Model.Validation[30000]
```

*No type was specified for the decimal column 'Price' on entity type 'Movie'. This will cause values to be silently truncated if they do not fit in the default precision and scale. Explicitly specify the SQL server column type that can accommodate all the values using 'ForHasColumnType()'.*

The `Add-Migration` command generates code to create the initial database schema. The schema is based on the model specified in the `RazorPagesMovieContext` (In the `Data/RazorPagesMovieContext.cs` file). The `Initial` argument is used to name the migrations. You can use any name, but by convention you choose a name that describes the migration. See [Introduction to migrations](#) for more information.

The `Update-Database` command runs the `Up` method in the `Migrations/{time-stamp}_InitialCreate.cs` file, which creates the database.

If you get the error:

```
SqlException: Cannot open database "RazorPagesMovieContext-GUID" requested by the login. The login failed.  
Login failed for user 'User-name'.
```

You missed the [migrations step](#).

By [Rick Anderson](#)

In this section, you add classes for managing movies in a database. You use these classes with [Entity Framework Core](#) (EF Core) to work with a database. EF Core is an object-relational mapping (ORM) framework that simplifies the data access code that you have to write.

The model classes you create are known as POCO classes (from "plain-old CLR objects") because they don't have any dependency on EF Core. They define the properties of the data that are stored in the database.

In this tutorial, you write the model classes first, and EF Core creates the database. An alternate approach not covered here is to [generate model classes from an existing database](#).

[View or download](#) sample.

## Add a data model

In Solution Explorer, right-click the **RazorPagesMovie** project > **Add > New Folder**. Name the folder **Models**.

Right click the **Models** folder. Select **Add > Class**. Name the class **Movie** and add the following properties:

Add the following properties to the `Movie` class:

```

using System;

namespace RazorPagesMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}

```

The `ID` field is required by the database for the primary key.

## Add a database context class

Add the following `MovieContext.cs` class to the `Models` folder:

```

using Microsoft.EntityFrameworkCore;

namespace RazorPagesMovie.Models
{
    public class MovieContext : DbContext
    {
        public MovieContext(DbContextOptions<MovieContext> options)
            : base(options)
        {

        }

        public DbSet<Movie> Movie { get; set; }
    }
}

```

The preceding code creates a `DbSet` property for the entity set. In Entity Framework terminology, an entity set typically corresponds to a database table, and an entity corresponds to a row in the table.

## Add a database connection string

Add a connection string to the `appsettings.json` file.

```

{
    "Logging": {
        "IncludeScopes": false,
        "LogLevel": {
            "Default": "Warning"
        }
    },
    "ConnectionStrings": {
        "MovieContext": "Server=(localdb)\\mssqllocaldb;Database=Movie-1;Trusted_Connection=True;MultipleActiveResultSets=true"
    }
}

```

## Register the database context

Register the database context with the [dependency injection](#) container in the [ConfigureServices method of the Startup class \(Startup.cs\)](#):

```

public void ConfigureServices(IServiceCollection services)
{
    // requires
    // using RazorPagesMovie.Models;
    // using Microsoft.EntityFrameworkCore;

    services.AddDbContext<MovieContext>(options =>
        options.UseSqlServer(Configuration.GetConnectionString("MovieContext")));
    services.AddMvc();
}

```

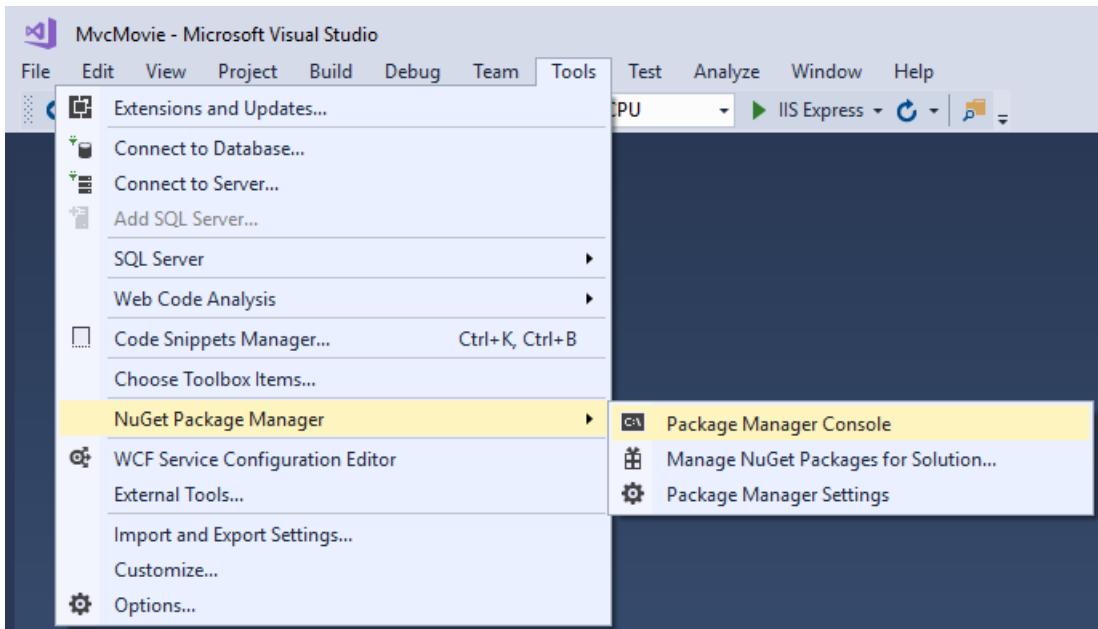

Build the project to verify you don't have any errors.

## Add scaffold tooling and perform initial migration

In this section, you use the Package Manager Console (PMC) to:

- Add the Visual Studio web code generation package. This package is required to run the scaffolding engine.
- Add an initial migration.
- Update the database with the initial migration.

From the **Tools** menu, select **NuGet Package Manager > Package Manager Console**.

In the PMC, enter the following commands:

```

Install-Package Microsoft.VisualStudio.Web.CodeGeneration.Design -Version 2.0.3
Add-Migration Initial
Update-Database

```

Alternatively, the following .NET Core CLI commands can be used:

```

dotnet add package Microsoft.VisualStudio.Web.CodeGeneration.Design
dotnet ef migrations add Initial
dotnet ef database update

```

Ignore the following message:

```
Microsoft.EntityFrameworkCore.Model.Validation[30000]
```

*No type was specified for the decimal column 'Price' on entity type 'Movie'. This will cause values to be silently truncated if they do not fit in the default precision and scale. Explicitly specify the SQL server column type that can accommodate all the values using 'ForHasColumnType()'*

You fix that in the next tutorial.

The `Install-Package` command installs the tooling required to run the scaffolding engine.

The `Add-Migration` command generates code to create the initial database schema. The schema is based on the model specified in the `DbContext` (In the `Models/MovieContext.cs` file). The `Initial` argument is used to name the migrations. You can use any name, but by convention you choose a name that describes the migration. See [Introduction to migrations](#) for more information.

The `Update-Database` command runs the `Up` method in the `Migrations/{time-stamp}_InitialCreate.cs` file, which creates the database.

### Scaffold the Movie model

- Run the following from the command line (in the project directory that contains the `Program.cs`, `Startup.cs`, and `.csproj` files):

```
dotnet restore  
dotnet aspnet-codegenerator razorpage -m Movie -dc MovieContext -udl -outDir Pages\Movies --  
referenceScriptLibraries
```

If you get the error:

```
No executable found matching command "dotnet-aspnet-codegenerator"
```

The preceding error happens when you are in the wrong directory. Open a command shell to the project directory (The directory that contains the `Program.cs`, `Startup.cs`, and `.csproj` files), and then run the preceding command.

If you get the error:

```
The process cannot access the file  
'RazorPagesMovie/bin/Debug/netcoreapp2.0/RazorPagesMovie.dll'  
because it is being used by another process.
```

Exit Visual Studio and run the command again.

The following table details the ASP.NET Core code generators` parameters:

PARAMETER	DESCRIPTION
<code>-m</code>	The name of the model.
<code>-dc</code>	The data context.
<code>-udl</code>	Use the default layout.
<code>-outDir</code>	The relative output folder path to create the views.
<code>--referenceScriptLibraries</code>	Adds <code>_ValidationScriptsPartial</code> to Edit and Create pages

Use the `-h` switch to get help on the `aspnet-codegenerator razorpage` command:

```
dotnet aspnet-codegenerator razorpage -h
```

## Test the app

- Run the app and append `/Movies` to the URL in the browser (`http://localhost:port/movies`).
- Test the **Create** link.

The screenshot shows a browser window titled "Create - Movie". The address bar indicates a secure connection to `https://localhost:44348/Movies/Create`. The page itself is titled "Create" and has a sub-section "Movie". It contains four input fields: "Title" (value: "The Good, the bad, and the ugly"), "Release Date" (value: "05/30/2018"), "Genre" (value: "Western"), and "Price" (value: "1.19"). Below these fields is a "Create" button. At the bottom of the page is a link "Back to List" and a copyright notice "© 2018 - RazorPagesMovie".

- Test the **Edit**, **Details**, and **Delete** links.

If you get a SQL exception, verify you have run migrations and updated the database.

The next tutorial explains the files created by scaffolding.

PREVIOUS: GET  
STARTED

NEXT: SCAFFOLDED RAZOR  
PAGES

# Scaffolded Razor Pages in ASP.NET Core

6/21/2018 • 8 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

This tutorial examines the Razor Pages created by scaffolding in the previous tutorial.

[View or download sample.](#)

## The Create, Delete, Details, and Edit pages.

Examine the *Pages/Movies/Index.cshtml.cs* Page Model:

```
using Microsoft.AspNetCore.Mvc.RazorPages;
using Microsoft.EntityFrameworkCore;
using System.Collections.Generic;
using System.Threading.Tasks;
using RazorPagesMovie.Models;

namespace RazorPagesMovie.Pages.Movies
{
    public class IndexModel : PageModel
    {
        private readonly RazorPagesMovie.Models.MovieContext _context;

        public IndexModel(RazorPagesMovie.Models.MovieContext context)
        {
            _context = context;
        }

        public IList<Movie> Movie { get; set; }

        public async Task OnGetAsync()
        {
            Movie = await _context.Movie.ToListAsync();
        }
    }
}
```

```

using Microsoft.AspNetCore.Mvc.RazorPages;
using Microsoft.EntityFrameworkCore;
using RazorPagesMovie.Models;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace RazorPagesMovie.Pages.Movies
{
    public class IndexModel : PageModel
    {
        private readonly RazorPagesMovie.Models.RazorPagesMovieContext _context;

        public IndexModel(RazorPagesMovie.Models.RazorPagesMovieContext context)
        {
            _context = context;
        }

        public IList<Movie> Movie { get; set; }

        public async Task OnGetAsync()
        {
            Movie = await _context.Movie.ToListAsync();
        }
    }
}

```

Razor Pages are derived from `PageModel`. By convention, the `PageModel`-derived class is called `<PageName>Model`. The constructor uses [dependency injection](#) to add the `MovieContext` to the page. All the scaffolded pages follow this pattern. See [Asynchronous code](#) for more information on asynchronous programming with Entity Framework.

When a request is made for the page, the `OnGetAsync` method returns a list of movies to the Razor Page. `OnGetAsync` or `OnGet` is called on a Razor Page to initialize the state for the page. In this case, `OnGetAsync` gets a list of movies and displays them.

When `OnGet` returns `void` or `OnGetAsync` returns `Task`, no return method is used. When the return type is `IActionResult` or `Task<IActionResult>`, a return statement must be provided. For example, the `Pages/Movies/Create.cshtml.cs` `OnPostAsync` method:

```

public async Task<IActionResult> OnPostAsync()
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    _context.Movie.Add(Movie);
    await _context.SaveChangesAsync();

    return RedirectToPage("./Index");
}

```

Examine the `Pages/Movies/Index.cshtml` Razor Page:

```

@page
@model RazorPagesMovie.Pages.Movies.IndexModel

 @{
    ViewData["Title"] = "Index";
}

<h2>Index</h2>

<p>
    <a asp-page="Create">Create New</a>
</p>
<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].Title)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].ReleaseDate)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].Genre)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].Price)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
@foreach (var item in Model.Movie) {
        <tr>
            <td>
                @Html.DisplayFor(modelItem => item.Title)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.ReleaseDate)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.Genre)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.Price)
            </td>
            <td>
                <a asp-page=".Edit" asp-route-id="@item.ID">Edit</a> |
                <a asp-page=".Details" asp-route-id="@item.ID">Details</a> |
                <a asp-page=".Delete" asp-route-id="@item.ID">Delete</a>
            </td>
        </tr>
}
    </tbody>
</table>

```

Razor can transition from HTML into C# or into Razor-specific markup. When an `@` symbol is followed by a [Razor reserved keyword](#), it transitions into Razor-specific markup, otherwise it transitions into C#.

The `@page` Razor directive makes the file into an MVC action — which means that it can handle requests. `@page` must be the first Razor directive on a page. `@page` is an example of transitioning into Razor-specific markup. See [Razor syntax](#) for more information.

Examine the lambda expression used in the following HTML Helper:

```
@Html.DisplayNameFor(model => model.Movie[0].Title)
```

The `DisplayNameFor` HTML Helper inspects the `Title` property referenced in the lambda expression to determine the display name. The lambda expression is inspected rather than evaluated. That means there is no access violation when `model`, `model.Movie`, or `model.Movie[0]` are `null` or empty. When the lambda expression is evaluated (for example, with `@Html.DisplayFor(modelItem => item.Title)`), the model's property values are evaluated.

### The `@model` directive

```
@page  
@model RazorPagesMovie.Pages.Movies.IndexModel
```

The `@model` directive specifies the type of the model passed to the Razor Page. In the preceding example, the `@model` line makes the `PageModel`-derived class available to the Razor Page. The model is used in the `@Html.DisplayNameFor` and `@Html.DisplayName` [HTML Helpers](#) on the page.

### ViewData and layout

Consider the following code:

```
@page  
@model RazorPagesMovie.Pages.Movies.IndexModel  
  
{@  
    ViewData["Title"] = "Index";  
}
```

The preceding highlighted code is an example of Razor transitioning into C#. The `{` and `}` characters enclose a block of C# code.

The `PageModel` base class has a `ViewData` dictionary property that can be used to add data that you want to pass to a View. You add objects into the `ViewData` dictionary using a key/value pattern. In the preceding sample, the "Title" property is added to the `ViewData` dictionary.

The "Title" property is used in the `Pages/_Layout.cshtml` file. The following markup shows the first few lines of the `Pages/_Layout.cshtml` file.

The "Title" property is used in the `Pages/Shared/_Layout.cshtml` file. The following markup shows the first few lines of the `_Layout.cshtml` file.

```
<!DOCTYPE html>  
<html>  
<head>  
    <meta charset="utf-8" />  
    <meta name="viewport" content="width=device-width, initial-scale=1.0" />  
    <title>@ViewData["Title"] - RazorPagesMovie</title>  
  
    /*Markup removed for brevity.*@
```

The line `/*Markup removed for brevity.*@` is a Razor comment. Unlike HTML comments (`<!-- -->`), Razor comments are not sent to the client.

Run the app and test the links in the project (**Home**, **About**, **Contact**, **Create**, **Edit**, and **Delete**). Each page sets the title, which you can see in the browser tab. When you bookmark a page, the title is used for the bookmark. `Pages/Index.cshtml` and `Pages/Movies/Index.cshtml` currently have the same title, but you can modify them to

have different values.

#### NOTE

You may not be able to enter decimal commas in the `Price` field. To support [jQuery validation](#) for non-English locales that use a comma (",") for a decimal point, and non US-English date formats, you must take steps to globalize your app. This [GitHub issue 4076](#) for instructions on adding decimal comma.

The `Layout` property is set in the *Pages/\_ViewStart.cshtml* file:

```
@{  
    Layout = "_Layout";  
}
```

The preceding markup sets the layout file to *Pages/\_Layout.cshtml* for all Razor files under the *Pages* folder. See [Layout](#) for more information.

#### Update the layout

Change the `<title>` element in the *Pages/\_Layout.cshtml* file to use a shorter string.

```
<!DOCTYPE html>  
<html>  
<head>  
    <meta charset="utf-8" />  
    <meta name="viewport" content="width=device-width, initial-scale=1.0" />  
    <title>@ ViewData["Title"] - Movie</title>
```

Find the following anchor element in the *Pages/\_Layout.cshtml* file.

```
<a asp-page="/Index" class="navbar-brand">RazorPagesMovie</a>
```

Replace the preceding element with the following markup.

```
<a asp-page="/Movies/Index" class="navbar-brand">RpMovie</a>
```

The preceding anchor element is a [Tag Helper](#). In this case, it's the [Anchor Tag Helper](#). The `asp-page="/Movies/Index"` Tag Helper attribute and value creates a link to the `/Movies/Index` Razor Page.

Save your changes, and test the app by clicking on the **RpMovie** link. See the *\_Layout.cshtml* file in GitHub.

#### The Create page model

Examine the *Pages/Movies/Create.cshtml.cs* page model:

```
// Unused usings removed.
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using RazorPagesMovie.Models;
using System.Threading.Tasks;

namespace RazorPagesMovie.Pages.Movies
{
    public class CreateModel : PageModel
    {
        private readonly RazorPagesMovie.Models.MovieContext _context;

        public CreateModel(RazorPagesMovie.Models.MovieContext context)
        {
            _context = context;
        }

        public IActionResult OnGet()
        {
            return Page();
        }

        [BindProperty]
        public Movie Movie { get; set; }

        public async Task<IActionResult> OnPostAsync()
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }

            _context.Movie.Add(Movie);
            await _context.SaveChangesAsync();

            return RedirectToPage("./Index");
        }
    }
}
```

```

// Unused usings removed.
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using RazorPagesMovie.Models;
using System.Threading.Tasks;

namespace RazorPagesMovie.Pages.Movies
{
    public class CreateModel : PageModel
    {
        private readonly RazorPagesMovie.Models.RazorPagesMovieContext _context;

        public CreateModel(RazorPagesMovie.Models.RazorPagesMovieContext context)
        {
            _context = context;
        }

        public IActionResult OnGet()
        {
            return Page();
        }

        [BindProperty]
        public Movie Movie { get; set; }

        public async Task<IActionResult> OnPostAsync()
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }

            _context.Movie.Add(Movie);
            await _context.SaveChangesAsync();

            return RedirectToPage("./Index");
        }
    }
}

```

The `OnGet` method initializes any state needed for the page. The Create page doesn't have any state to initialize, so `Page` is returned. Later in the tutorial you see `OnGet` method initialize state. The `Page` method creates a `PageResult` object that renders the *Create.cshtml* page.

The `Movie` property uses the `[BindProperty]` attribute to opt-in to [model binding](#). When the Create form posts the form values, the ASP.NET Core runtime binds the posted values to the `Movie` model.

The `OnPostAsync` method is run when the page posts form data:

```

public async Task<IActionResult> OnPostAsync()
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    _context.Movie.Add(Movie);
    await _context.SaveChangesAsync();

    return RedirectToPage("./Index");
}

```

If there are any model errors, the form is redisplayed, along with any form data posted. Most model errors can be

caught on the client-side before the form is posted. An example of a model error is posting a value for the date field that cannot be converted to a date. We'll talk more about client-side validation and model validation later in the tutorial.

If there are no model errors, the data is saved, and the browser is redirected to the Index page.

## The Create Razor Page

Examine the *Pages/Movies/Create.cshtml* Razor Page file:

```
@page
@model RazorPagesMovie.Pages.Movies.CreateModel

 @{
    ViewData["Title"] = "Create";
}

<h2>Create</h2>

<h4>Movie</h4>
<hr />
<div class="row">
    <div class="col-md-4">
        <form method="post">
            <div asp-validation-summary="ModelOnly" class="text-danger"></div>
            <div class="form-group">
                <label asp-for="Movie.Title" class="control-label"></label>
                <input asp-for="Movie.Title" class="form-control" />
                <span asp-validation-for="Movie.Title" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Movie.ReleaseDate" class="control-label"></label>
                <input asp-for="Movie.ReleaseDate" class="form-control" />
                <span asp-validation-for="Movie.ReleaseDate" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Movie.Genre" class="control-label"></label>
                <input asp-for="Movie.Genre" class="form-control" />
                <span asp-validation-for="Movie.Genre" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Movie.Price" class="control-label"></label>
                <input asp-for="Movie.Price" class="form-control" />
                <span asp-validation-for="Movie.Price" class="text-danger"></span>
            </div>
            <div class="form-group">
                <input type="submit" value="Create" class="btn btn-default" />
            </div>
        </form>
    </div>
</div>

<div>
    <a asp-page="Index">Back to List</a>
</div>

@section Scripts {
    @{await Html.RenderPartialAsync("_ValidationScriptsPartial");}
}
```

Visual Studio displays the `<form method="post">` tag in a distinctive font used for Tag Helpers:

```
1  @page
2  @model RazorPagesMovie.Pages_Movie.CreateModel
3
4  @{
5      ViewData["Title"] = "Create";
6  }
7
8  <h2>Create</h2>
9
10 <h4>Movie</h4>
11 <hr />
12 <div class="row">
13     <div class="col-md-4">
14         <form method="post">
15
16             The form element represents a collection of form-associated elements, some of which can represent editable values that can be submitted to a server for processing.
17
18             Learn more \(F1\)
19
20
21             Microsoft.AspNetCore.Mvc.TagHelpers.FormTagHelper
22             Microsoft.AspNetCore.Razor.TagHelpers.TagHelper implementation targeting <form> elements.
23
24                 <span asp-validation-for="Movie.ReleaseDate" class="text-danger">
25                     </div>
26                     <div class="form-group">
27                         <label asp-for="Movie.Genre" class="control-label"></label>
28                         <input asp-for="Movie.Genre" class="form-control" />
29                         <span asp-validation-for="Movie.Genre" class="text-danger"></span>
30                     </div>
31                     <div class="form-group">
32                         <label asp-for="Movie.Price" class="control-label"></label>
33                         <input asp-for="Movie.Price" class="form-control" />
34                         <span asp-validation-for="Movie.Price" class="text-danger"></span>
35                     </div>
36                     <div class="form-group">
37                         <input type="submit" value="Create" class="btn btn-default" />
38                     </div>
39                 </form>
40             </div>

```

The `<form method="post">` element is a [Form Tag Helper](#). The Form Tag Helper automatically includes an [antiforgery token](#).

The scaffolding engine creates Razor markup for each field in the model (except the ID) similar to the following:

```
<div asp-validation-summary="ModelOnly" class="text-danger"></div>
<div class="form-group">
    <label asp-for="Movie.Title" class="control-label"></label>
    <input asp-for="Movie.Title" class="form-control" />
    <span asp-validation-for="Movie.Title" class="text-danger"></span>
</div>
```

The [Validation Tag Helpers](#) (`<div asp-validation-summary` and `<span asp-validation-for`) display validation errors. Validation is covered in more detail later in this series.

The [Label Tag Helper](#) (`<label asp-for="Movie.Title" class="control-label"></label>`) generates the label caption and `for` attribute for the `Title` property.

The [Input Tag Helper](#) (`<input asp-for="Movie.Title" class="form-control" />`) uses the [DataAnnotations](#) attributes and produces HTML attributes needed for jQuery Validation on the client-side.

The next tutorial explains SQL Server LocalDB and seeding the database.

# Work with SQL Server LocalDB and ASP.NET Core

7/6/2018 • 4 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Joe Audette](#)

The `MovieContext` object handles the task of connecting to the database and mapping `Movie` objects to database records. The database context is registered with the [Dependency Injection](#) container in the `ConfigureServices` method in the `Startup.cs` file:

```
public void ConfigureServices(IServiceCollection services)
{
    // requires
    // using RazorPagesMovie.Models;
    // using Microsoft.EntityFrameworkCore;

    services.AddDbContext<MovieContext>(options =>
        options.UseSqlServer(Configuration.GetConnectionString("MovieContext")));
    services.AddMvc();
}
```

```
public void ConfigureServices(IServiceCollection services)
{
    services.Configure<CookiePolicyOptions>(options =>
    {
        options.CheckConsentNeeded = context => true;
        options.MinimumSameSitePolicy = SameSiteMode.None;
    });

    services.AddMvc().SetCompatibilityVersion(CompatibilityVersion.Version_2_1);

    services.AddDbContext<RazorPagesMovieContext>(options =>
        options.UseSqlServer(Configuration.GetConnectionString("RazorPagesMovieContext")));
}
```

For more information on the methods used in `ConfigureServices`, see:

- [EU General Data Protection Regulation \(GDPR\) support in ASP.NET Core for `CookiePolicyOptions`](#).
- [SetCompatibilityVersion](#)

The ASP.NET Core [Configuration](#) system reads the `ConnectionString`. For local development, it gets the connection string from the `appsettings.json` file. The name value for the database (`Database={Database name}`) will be different for your generated code. The name value is arbitrary.

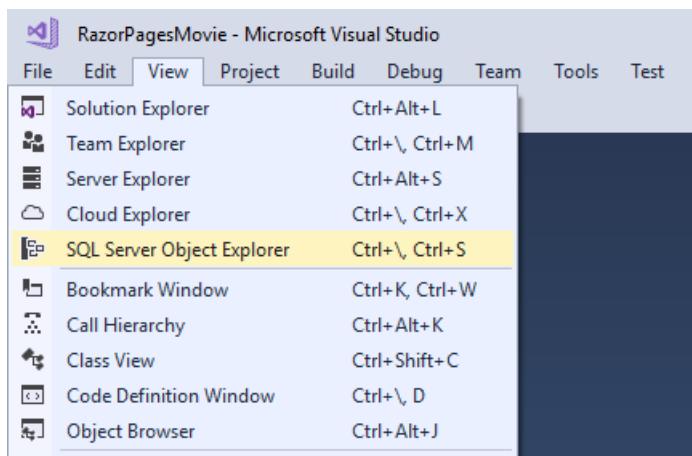

```
"ConnectionStrings": {
    "MovieContext": "Server=(localdb)\\mssqllocaldb;Database=Movie-
    1;Trusted_Connection=True;MultipleActiveResultSets=true"
}
```

When you deploy the app to a test or production server, you can use an environment variable or another approach to set the connection string to a real SQL Server. See [Configuration](#) for more information.

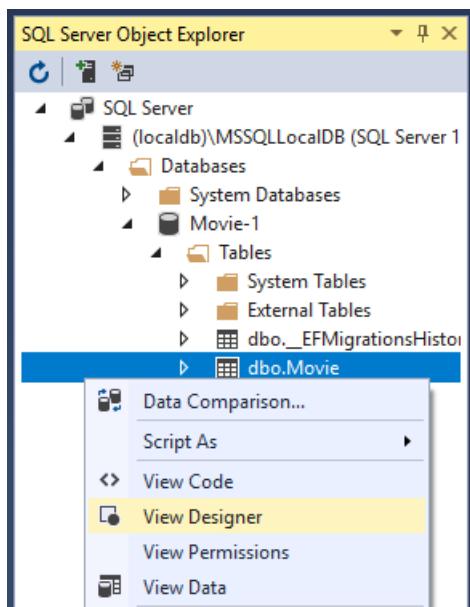

## SQL Server Express LocalDB

LocalDB is a lightweight version of the SQL Server Express Database Engine that's targeted for program development. LocalDB starts on demand and runs in user mode, so there's no complex configuration. By default, LocalDB database creates "\*.mdf" files in the C:/Users/<user> directory.

- From the **View** menu, open **SQL Server Object Explorer** (SSOX).

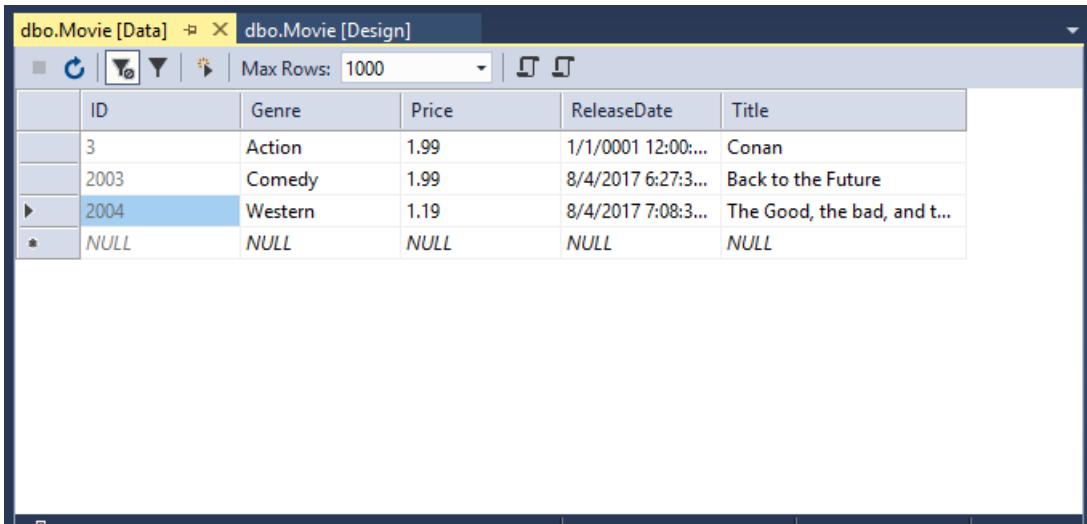

- Right click on the **Movie** table and select **View Designer**:

A screenshot of the SQL Server Object Explorer showing the 'Design' tab for the 'dbo.Movie' table. The table structure is displayed in a grid with columns: Name, Data Type, Allow Nulls, and Default. The rows represent the columns: ID, Genre, Price, ReleaseDate, and Title. To the right of the table, there is a sidebar with sections for Keys (1), Check Constraints (0), Indexes (0), Foreign Keys (0), and Triggers (0). Below the table, there is a T-SQL script window containing the CREATE TABLE statement for the 'Movie' table. The script includes columns for ID, Genre, Price, ReleaseDate, and Title, with ID being the primary key.

Note the key icon next to `ID`. By default, EF creates a property named `ID` for the primary key.

- Right click on the `Movie` table and select **View Data**:

The screenshot shows a database interface with two tabs at the top: "dbo.Movie [Data]" and "dbo.Movie [Design]". The "dbo.Movie [Data]" tab is selected, indicated by a yellow background. Below the tabs is a toolbar with icons for refresh, search, and other database operations. A dropdown menu "Max Rows: 1000" is open. The main area displays a table with five columns: ID, Genre, Price, ReleaseDate, and Title. There are four data rows and one empty row marked with an asterisk (\*). The first row has an ID of 3, Action genre, and a price of 1.99. The second row has an ID of 2003, Comedy genre, and a price of 1.99. The third row has an ID of 2004, Western genre, and a price of 1.19. The fourth row is empty, with all columns showing "NULL".

	ID	Genre	Price	ReleaseDate	Title
	3	Action	1.99	1/1/0001 12:00:...	Conan
	2003	Comedy	1.99	8/4/2017 6:27:3...	Back to the Future
▶	2004	Western	1.19	8/4/2017 7:08:3...	The Good, the bad, and t...
*	NULL	NULL	NULL	NULL	NULL

## Seed the database

Create a new class named `SeedData` in the *Models* folder. Replace the generated code with the following:

```
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using System;
using System.Linq;

namespace RazorPagesMovie.Models
{
    public static class SeedData
    {
        public static void Initialize(IServiceProvider serviceProvider)
        {
            using (var context = new MovieContext(
                serviceProvider.GetRequiredService<DbContextOptions<MovieContext>>()))
            {
                // Look for any movies.
                if (context.Movie.Any())
                {
                    return; // DB has been seeded
                }

                context.Movie.AddRange(
                    new Movie
                    {
                        Title = "When Harry Met Sally",
                        ReleaseDate = DateTime.Parse("1989-2-12"),
                        Genre = "Romantic Comedy",
                        Price = 7.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters",
                        ReleaseDate = DateTime.Parse("1984-3-13"),
                        Genre = "Comedy",
                        Price = 8.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters 2",
                        ReleaseDate = DateTime.Parse("1986-2-23"),
                        Genre = "Comedy",
                        Price = 9.99M
                    },
                    new Movie
                    {
                        Title = "Rio Bravo",
                        ReleaseDate = DateTime.Parse("1959-4-15"),
                        Genre = "Western",
                        Price = 3.99M
                    }
                );
                context.SaveChanges();
            }
        }
    }
}
```

```

using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using System;
using System.Linq;

namespace RazorPagesMovie.Models
{
    public static class SeedData
    {
        public static void Initialize(IServiceProvider serviceProvider)
        {
            using (var context = new RazorPagesMovieContext(
                serviceProvider.GetRequiredService<DbContextOptions<RazorPagesMovieContext>>()))
            {
                // Look for any movies.
                if (context.Movie.Any())
                {
                    return; // DB has been seeded
                }

                context.Movie.AddRange(
                    new Movie
                    {
                        Title = "When Harry Met Sally",
                        ReleaseDate = DateTime.Parse("1989-2-12"),
                        Genre = "Romantic Comedy",
                        Price = 7.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters ",
                        ReleaseDate = DateTime.Parse("1984-3-13"),
                        Genre = "Comedy",
                        Price = 8.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters 2",
                        ReleaseDate = DateTime.Parse("1986-2-23"),
                        Genre = "Comedy",
                        Price = 9.99M
                    },
                    new Movie
                    {
                        Title = "Rio Bravo",
                        ReleaseDate = DateTime.Parse("1959-4-15"),
                        Genre = "Western",
                        Price = 3.99M
                    }
                );
                context.SaveChanges();
            }
        }
    }
}

```

If there are any movies in the DB, the seed initializer returns and no movies are added.

```
if (context.Movie.Any())
{
    return; // DB has been seeded.
}
```

## Add the seed initializer

In *Program.cs*, modify the `Main` method to do the following:

- Get a DB context instance from the dependency injection container.
- Call the seed method, passing to it the context.
- Dispose the context when the seed method completes.

The following code shows the updated *Program.cs* file.

```
// Unused usings removed.
using Microsoft.AspNetCore;
using Microsoft.AspNetCore.Hosting;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Logging;
using RazorPagesMovie.Models;
using System;
using Microsoft.EntityFrameworkCore;

namespace RazorPagesMovie
{
    public class Program
    {
        public static void Main(string[] args)
        {
            var host = BuildWebHost(args);

            using (var scope = host.Services.CreateScope())
            {
                var services = scope.ServiceProvider;

                try
                {
                    var context = services.GetRequiredService<MovieContext>();
                    // requires using Microsoft.EntityFrameworkCore;
                    context.Database.Migrate();
                    // Requires using RazorPagesMovie.Models;
                    SeedData.Initialize(services);
                }
                catch (Exception ex)
                {
                    var logger = services.GetRequiredService<ILogger<Program>>();
                    logger.LogError(ex, "An error occurred seeding the DB.");
                }
            }

            host.Run();
        }

        public static IWebHost BuildWebHost(string[] args) =>
            WebHost.CreateDefaultBuilder(args)
                .UseStartup<Startup>()
                .Build();
    }
}
```

```

using Microsoft.AspNetCore;
using Microsoft.AspNetCore.Hosting;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Logging;
using RazorPagesMovie.Models;
using System;
using Microsoft.EntityFrameworkCore;

namespace RazorPagesMovie
{
    public class Program
    {
        public static void Main(string[] args)
        {
            var host = CreateWebHostBuilder(args).Build();

            using (var scope = host.Services.CreateScope())
            {
                var services = scope.ServiceProvider;

                try
                {
                    var context = services.GetRequiredService<RazorPagesMovieContext>();
                    context.Database.Migrate();
                    SeedData.Initialize(services);
                }
                catch (Exception ex)
                {
                    var logger = services.GetRequiredService<ILogger<Program>>();
                    logger.LogError(ex, "An error occurred seeding the DB.");
                }
            }

            host.Run();
        }

        public static IWebHostBuilder CreateWebHostBuilder(string[] args) =>
            WebHost.CreateDefaultBuilder(args)
                .UseStartup<Startup>();
    }
}

```

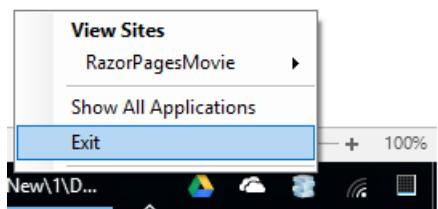

A production app would not call `Database.Migrate`. It's added to the preceding code to prevent the following exception when `Update-Database` has not been run:

`SqlException: Cannot open database "RazorPagesMovieContext-21" requested by the login. The login failed. Login failed for user 'user name'.`

## Test the app

- Delete all the records in the DB. You can do this with the delete links in the browser or from [SSOX](#)
- Force the app to initialize (call the methods in the `Startup` class) so the seed method runs. To force initialization, IIS Express must be stopped and restarted. You can do this with any of the following approaches:
  - Right click the IIS Express system tray icon in the notification area and tap **Exit** or **Stop Site**:

- o If you were running VS in non-debug mode, press F5 to run in debug mode.
- o If you were running VS in debug mode, stop the debugger and press F5.

The app shows the seeded data:

A screenshot of a Microsoft Edge browser window. The title bar says 'Index - Movie'. The address bar shows the URL 'localhost:5000/Movies'. The main content area displays a table titled 'Index' with the following data:

Title	ReleaseDate	Genre	Price	
When Harry Met Sally	2/12/1989 12:00:00 AM	Romantic Comedy	7.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Ghostbusters	3/13/1984 12:00:00 AM	Comedy	8.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Ghostbusters 2	2/23/1986 12:00:00 AM	Comedy	9.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Rio Bravo	4/15/1959 12:00:00 AM	Western	3.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

At the bottom left, it says '© 2017 - RazorPagesMovie'. A watermark 'Window Snip' is visible in the bottom right corner of the browser window.

The next tutorial will clean up the presentation of the data.

PAGES](#)

[NEXT: UPDATING THE  
PAGES](#)

# Update the generated pages in an ASP.NET Core app

6/21/2018 • 5 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

We have a good start to the movie app, but the presentation isn't ideal. We don't want to see the time (12:00:00 AM in the image below) and **ReleaseDate** should be **Release Date** (two words).

Title	ReleaseDate	Genre	Price	
When Harry Met Sally	2/12/1989 12:00:00 AM	Romantic Comedy	7.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Ghostbusters	3/13/1984 12:00:00 AM	Comedy	8.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Ghostbusters 2	2/23/1986 12:00:00 AM	Comedy	9.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Rio Bravo	4/15/1959 12:00:00 AM	Western	3.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

© 2017 - RazorPagesMovie

Window Snip

## Update the generated code

Open the *Models/Movie.cs* file and add the highlighted lines shown in the following code:

```
using System;

namespace RazorPagesMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }

        [Display(Name = "Release Date")]
        [DataType(DataType.Date)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

```

using System;

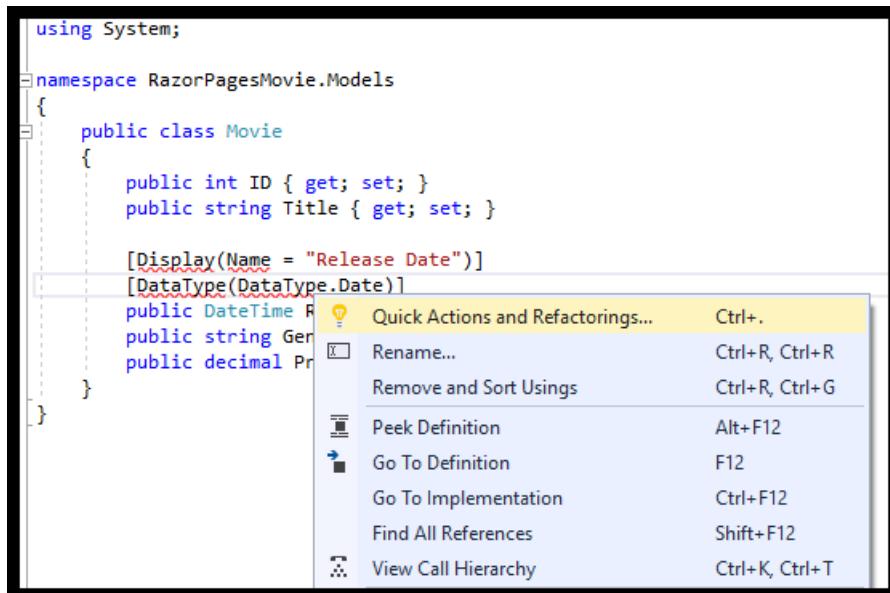

namespace RazorPagesMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }

        [Display(Name = "Release Date")]
        [DataType(DataType.Date)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }

        [Column(TypeName = "decimal(18, 2)")]
        public decimal Price { get; set; }
    }
}

```

Right click on a red squiggly line > **Quick Actions and Refactorings**.

Select `using System.ComponentModel.DataAnnotations;`

Visual studio adds `using System.ComponentModel.DataAnnotations;`.

Right click on a red squiggly line > **Quick Actions and Refactorings** on the `[Column]` attribute and select

`using System.ComponentModel.DataAnnotations.Schema;`

The `[Column(TypeName = "decimal(18, 2)")]` data annotation is required so Entity Framework Core can correctly map `Price` to currency in the database. For more information, see [Data Types](#).

The completed model:

```
using System;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace RazorPagesMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }

        [Display(Name = "Release Date")]
        [DataType(DataType.Date)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }

        [Column(TypeName = "decimal(18, 2)")]
        public decimal Price { get; set; }
    }
}
```

We'll cover [DataAnnotations](#) in the next tutorial. The [Display](#) attribute specifies what to display for the name of a field (in this case "Release Date" instead of "ReleaseDate"). The [DataType](#) attribute specifies the type of the data (Date), so the time information stored in the field isn't displayed.

Browse to Pages/Movies and hover over an **Edit** link to see the target URL.

Title	Release Date	Genre	Price	
When Harry Met Sally	2/12/1989	Romantic Comedy	7.99	<a href="#">Edit</a> <a href="#">Details</a> <a href="#">Delete</a>
Ghostbusters	3/13/1984	Comedy	8.99	<a href="#">Edit</a> <a href="#">Details</a> <a href="#">Delete</a>
Ghostbusters 2	2/23/1986	Comedy	9.99	<a href="#">Edit</a> <a href="#">Details</a> <a href="#">Delete</a>
Rio Bravo	4/15/1959	Western	3.99	<a href="#">Edit</a> <a href="#">Details</a> <a href="#">Delete</a>

The **Edit**, **Details**, and **Delete** links are generated by the [Anchor Tag Helper](#) in the *Pages/Movies/Index.cshtml* file.

```

@foreach (var item in Model.Movie) {
    <tr>
        <td>
            @Html.DisplayFor(modelItem => item.Title)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.ReleaseDate)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.Genre)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.Price)
        </td>
        <td>
            <a asp-page="./Edit" asp-route-id="@item.ID">Edit</a> | 
            <a asp-page="./Details" asp-route-id="@item.ID">Details</a> | 
            <a asp-page="./Delete" asp-route-id="@item.ID">Delete</a>
        </td>
    </tr>
}
</tbody>
</table>

```

Tag Helpers enable server-side code to participate in creating and rendering HTML elements in Razor files. In the preceding code, the `AnchorTagHelper` dynamically generates the HTML `href` attribute value from the Razor Page (the route is relative), the `asp-page`, and the route id (`asp-route-id`). See [URL generation for Pages](#) for more information.

Use **View Source** from your favorite browser to examine the generated markup. A portion of the generated HTML is shown below:

```

<td>
    <a href="/Movies/Edit?id=1">Edit</a> | 
    <a href="/Movies/Details?id=1">Details</a> | 
    <a href="/Movies/Delete?id=1">Delete</a>
</td>

```

The dynamically-generated links pass the movie ID with a query string (for example,

`http://localhost:5000/Movies/Details?id=2`).

Update the Edit, Details, and Delete Razor Pages to use the "`{id:int}`" route template. Change the page directive for each of these pages from `@page` to `@page "{id:int}"`. Run the app and then view source. The generated HTML adds the ID to the path portion of the URL:

```

<td>
    <a href="/Movies/Edit/1">Edit</a> | 
    <a href="/Movies/Details/1">Details</a> | 
    <a href="/Movies/Delete/1">Delete</a>
</td>

```

A request to the page with the "`{id:int}`" route template that does **not** include the integer will return an HTTP 404 (not found) error. For example, `http://localhost:5000/Movies/Details` will return a 404 error. To make the ID optional, append `?` to the route constraint:

```

@page "{id:int?}"

```

## Update concurrency exception handling

Update the `OnPostAsync` method in the `Pages/Movies/Edit.cshtml.cs` file. The following highlighted code shows the changes:

```
public async Task<IActionResult> OnPostAsync()
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    _context.Attach(Movie).State = EntityState.Modified;

    try
    {
        await _context.SaveChangesAsync();
    }
    catch (DbUpdateConcurrencyException)
    {
        if (!_context.Movie.Any(e => e.ID == Movie.ID))
        {
            return NotFound();
        }
        else
        {
            throw;
        }
    }

    return RedirectToPage("./Index");
}
```

The previous code only detects concurrency exceptions when the first concurrent client deletes the movie, and the second concurrent client posts changes to the movie.

To test the `catch` block:

- Set a breakpoint on `catch (DbUpdateConcurrencyException)`
- Edit a movie.
- In another browser window, select the **Delete** link for the same movie, and then delete the movie.
- In the previous browser window, post changes to the movie.

Production code would generally detect concurrency conflicts when two or more clients concurrently updated a record. See [Handle concurrency conflicts](#) for more information.

### Posting and binding review

Examine the `Pages/Movies/Edit.cshtml.cs` file:

```
public class EditModel : PageModel
{
    private readonly RazorPagesMovie.Models.MovieContext _context;

    public EditModel(RazorPagesMovie.Models.MovieContext context)
    {
        _context = context;
    }

    [BindProperty]
    public Movie Movie { get; set; }

    public async Task<IActionResult> OnGetAsync(int? id)
    {
        if (id == null)
        {
            return NotFound();
        }

        Movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);

        if (Movie == null)
        {
            return NotFound();
        }
        return Page();
    }

    public async Task<IActionResult> OnPostAsync()
    {
        if (!ModelState.IsValid)
        {
            return Page();
        }

        _context.Attach(Movie).State = EntityState.Modified;

        try
        {
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!_context.Movie.Any(e => e.ID == Movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }

        return RedirectToPage("./Index");
    }
}
```

```

public class EditModel : PageModel
{
    private readonly RazorPagesMovie.Models.RazorPagesMovieContext _context;

    public EditModel(RazorPagesMovie.Models.RazorPagesMovieContext context)
    {
        _context = context;
    }

    [BindProperty]
    public Movie Movie { get; set; }

    public async Task<IActionResult> OnGetAsync(int? id)
    {
        if (id == null)
        {
            return NotFound();
        }

        Movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);

        if (Movie == null)
        {
            return NotFound();
        }
        return Page();
    }

    public async Task<IActionResult> OnPostAsync()
    {
        if (!ModelState.IsValid)
        {
            return Page();
        }

        _context.Attach(Movie).State = EntityState.Modified;

        try
        {
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!_context.Movie.Any(e => e.ID == Movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
    }

    return RedirectToPage("./Index");
}
}

```

When an HTTP GET request is made to the Movies/Edit page (for example, `http://localhost:5000/Movies/Edit/2`):

- The `OnGetAsync` method fetches the movie from the database and returns the `Page` method.
- The `Page` method renders the `Pages/Movies/Edit.cshtml` Razor Page. The `Pages/Movies/Edit.cshtml` file contains the model directive (`@model RazorPagesMovie.Pages.Movies.EditModel`), which makes the movie model available on the page.
- The Edit form is displayed with the values from the movie.

When the Movies/Edit page is posted:

- The form values on the page are bound to the `Movie` property. The `[BindProperty]` attribute enables [Model binding](#).

```
[BindProperty]  
public Movie Movie { get; set; }
```

- If there are errors in the model state (for example, `ReleaseDate` cannot be converted to a date), the form is posted again with the submitted values.
- If there are no model errors, the movie is saved.

The HTTP GET methods in the Index, Create, and Delete Razor pages follow a similar pattern. The HTTP POST `OnPostAsync` method in the Create Razor Page follows a similar pattern to the `OnPostAsync` method in the Edit Razor Page.

Search is added in the next tutorial.

[PREVIOUS: WORKING WITH SQL SERVER](#)

[LOCALDB](#)

[ADD](#)

[SEARCH](#)

# Add search to ASP.NET Core Razor Pages

6/21/2018 • 3 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this document, search capability is added to the Index page that enables searching movies by *genre* or *name*.

Update the Index page's `OnGetAsync` method with the following code:

```
public async Task OnGetAsync(string searchString)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    Movie = await movies.ToListAsync();
}
```

The first line of the `OnGetAsync` method creates a [LINQ](#) query to select the movies:

```
var movies = from m in _context.Movie
             select m;
```

The query is *only* defined at this point, it has **not** been run against the database.

If the `searchString` parameter contains a string, the movies query is modified to filter on the search string:

```
if (!String.IsNullOrEmpty(searchString))
{
    movies = movies.Where(s => s.Title.Contains(searchString));
}
```

The `s => s.Title.Contains()` code is a [Lambda Expression](#). Lambdas are used in method-based [LINQ](#) queries as arguments to standard query operator methods such as the `Where` method or `Contains` (used in the preceding code). LINQ queries are not executed when they're defined or when they're modified by calling a method (such as `Where`, `Contains` or `OrderBy`). Rather, query execution is deferred. That means the evaluation of an expression is delayed until its realized value is iterated over or the `ToListAsync` method is called. See [Query Execution](#) for more information.

**Note:** The `Contains` method is run on the database, not in the C# code. The case sensitivity on the query depends on the database and the collation. On SQL Server, `Contains` maps to [SQL LIKE](#), which is case insensitive. In SQLite, with the default collation, it's case sensitive.

Navigate to the Movies page and append a query string such as `?searchString=Ghost` to the URL (for example, `http://localhost:5000/Movies?searchString=Ghost`). The filtered movies are displayed.

The screenshot shows a browser window with the title "Index - Movie". The address bar contains "localhost:5000/Movies?searchString=Ghost". The main content area is titled "RpMovie" and has a "Index" heading. Below it is a "Create New" link. A table lists two movies: "Ghostbusters" (3/13/1984, Comedy, 8.99) and "Ghostbusters 2" (2/23/1986, Comedy, 9.99). Each movie row has "Edit | Details | Delete" links. At the bottom, there is a copyright notice: "© 2017 - RazorPagesMovie".

If the following route template is added to the Index page, the search string can be passed as a URL segment (for example, `http://localhost:5000/Movies/Ghost`).

```
@page "{searchString?}"
```

The preceding route constraint allows searching the title as route data (a URL segment) instead of as a query string value. The `?` in `"{searchString?}"` means this is an optional route parameter.

The screenshot shows a browser window with the title "Index - Movie". The address bar contains "localhost:5000/Movies/Ghost". The main content area is titled "RpMovie" and has a "Index" heading. Below it is a "Create New" link. A table lists two movies: "Ghostbusters" (3/13/1984, Comedy, 8.99) and "Ghostbusters 2" (2/23/1986, Comedy, 9.99). Each movie row has "Edit | Details | Delete" links. At the bottom, there is a copyright notice: "© 2017 - RazorPagesMovie".

However, you can't expect users to modify the URL to search for a movie. In this step, UI is added to filter movies. If you added the route constraint `"{searchString?}"`, remove it.

Open the `Pages/Movies/Index.cshtml` file, and add the `<form>` markup highlighted in the following code:

```

@page
@model RazorPagesMovie.Pages.Movies.IndexModel

 @{
     ViewData["Title"] = "Index";
 }

<h2>Index</h2>

<p>
    <a href="#" asp-page="Create">Create New</a>
</p>

<form>
    <p>
        Title: <input type="text" name="SearchString">
        <input type="submit" value="Filter" />
    </p>
</form>

<table class="table">
    @*Markup removed for brevity.*@

```

The HTML `<form>` tag uses the [Form Tag Helper](#). When the form is submitted, the filter string is sent to the `Pages/Movies/Index` page. Save the changes and test the filter.

Title	Release Date	Genre	Price	
Ghostbusters	3/13/1984	Comedy	8.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Ghostbusters 2	2/23/1986	Comedy	9.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

© 2017 - RazorPagesMovie

## Search by genre

Add the following highlighted properties to `Pages/Movies/Index.cshtml.cs`:

```
public class IndexModel : PageModel
{
    private readonly RazorPagesMovie.Models.MovieContext _context;

    public IndexModel(RazorPagesMovie.Models.MovieContext context)
    {
        _context = context;
    }

    public IList<Movie> Movie { get; set; }
    public SelectList Genres { get; set; }
    public string MovieGenre { get; set; }
```

```
public class IndexModel : PageModel
{
    private readonly RazorPagesMovie.Models.RazorPagesMovieContext _context;

    public IndexModel(RazorPagesMovie.Models.RazorPagesMovieContext context)
    {
        _context = context;
    }

    public IList<Movie> Movie { get; set; }
    public SelectList Genres { get; set; }
    public string MovieGenre { get; set; }
```

The `SelectList Genres` contains the list of genres. This allows the user to select a genre from the list.

The `MovieGenre` property contains the specific genre the user selects (for example, "Western").

Update the `OnGetAsync` method with the following code:

```
// Requires using Microsoft.AspNetCore.Mvc.Rendering;
public async Task OnGetAsync(string movieGenre, string searchString)
{
    // Use LINQ to get list of genres.
    IQueryable<string> genreQuery = from m in _context.Movie
                                         orderby m.Genre
                                         select m.Genre;

    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    if (!String.IsNullOrEmpty(movieGenre))
    {
        movies = movies.Where(x => x.Genre == movieGenre);
    }
    Genres = new SelectList(await genreQuery.Distinct().ToListAsync());
    Movie = await movies.ToListAsync();
}
```

The following code is a LINQ query that retrieves all the genres from the database.

```
// Use LINQ to get list of genres.  
IQueryable<string> genreQuery = from m in _context.Movie  
                                orderby m.Genre  
                                select m.Genre;
```

The `SelectList` of genres is created by projecting the distinct genres.

```
Genres = new SelectList(await genreQuery.Distinct().ToListAsync());
```

## Adding search by genre

Update `Index.cshtml` as follows:

```
@page  
@model RazorPagesMovie.Pages.Movies.IndexModel  
  
{@  
    ViewData["Title"] = "Index";  
}  
  
<h2>Index</h2>  
  
<p>  
    <a asp-page="Create">Create New</a>  
</p>  
  
<form>  
    <p>  
        <select asp-for="MovieGenre" asp-items="Model.Genres">  
            <option value="">All</option>  
        </select>  
  
        Title: <input type="text" name="SearchString">  
        <input type="submit" value="Filter" />  
    </p>  
</form>  
  
<table class="table">  
    <thead>
```

Test the app by searching by genre, by movie title, and by both.

PREVIOUS: UPDATING THE  
PAGES

NEXT: ADDING A NEW  
FIELD

# Add a new field to a Razor Page in ASP.NET Core

6/21/2018 • 4 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section you use [Entity Framework](#) Code First Migrations to add a new field to the model and migrate that change to the database.

When using EF Code First to automatically create a database, Code First:

- Adds a table to the database to track whether the schema of the database is in sync with the model classes it was generated from.
- If the model classes aren't in sync with the DB, EF throws an exception.

Automatic verification of schema/model in sync makes it easier to find inconsistent database/code issues.

## Adding a Rating Property to the Movie Model

Open the `Models/Movie.cs` file and add a `Rating` property:

```
public class Movie
{
    public int ID { get; set; }
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }
    public string Genre { get; set; }
    public decimal Price { get; set; }
    public string Rating { get; set; }
}
```

```
public class Movie
{
    public int ID { get; set; }
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }
    public string Genre { get; set; }

    [Column(TypeName = "decimal(18, 2)")]
    public decimal Price { get; set; }
    public string Rating { get; set; }
}
```

Build the app (Ctrl+Shift+B).

Edit `Pages/Movies/Index.cshtml`, and add a `Rating` field:

```
@page
@model RazorPagesMovie.Pages.Movies.IndexModel

{@{
```

```

    ViewData["Title"] = "Index";
}

<h2>Index</h2>

<p>
    <a asp-page="Create">Create New</a>
</p>

<form>
    <p>
        <select asp-for="MovieGenre" asp-items="Model.Genres">
            <option value="">All</option>
        </select>

        Title: <input type="text" name="SearchString">
        <input type="submit" value="Filter" />
    </p>
</form>

<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].Title)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].ReleaseDate)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].Genre)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].Price)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].Rating)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
        @foreach (var item in Model.Movie) {
            <tr>
                <td>
                    @Html.DisplayFor(modelItem => item.Title)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.ReleaseDate)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Genre)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Price)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Rating)
                </td>
                <td>
                    <a asp-page=".Edit" asp-route-id="@item.ID">Edit</a> |
                    <a asp-page=".Details" asp-route-id="@item.ID">Details</a> |
                    <a asp-page=".Delete" asp-route-id="@item.ID">Delete</a>
                </td>
            </tr>
        }
    </tbody>
</table>

```

Add the `Rating` field to the Delete and Details pages.

Update `Create.cshtml` with a `Rating` field. You can copy/paste the previous `<div>` element and let intelliSense help you update the fields. IntelliSense works with [Tag Helpers](#).

```
    <div class="form-group">
        <label asp-for="Movie.Price" class="control-label"></label>
        <input asp-for="Movie.Price" class="form-control" />
        <span asp-validation-for="Movie.Price" class="text-danger"></span>
    </div>
    <div class="form-group">
        <label asp-for="Movie." class="control-label"></label>
        <input asp-for="Movie." class="form-control" />
        <span asp-validation-for="Movie." class="text-danger"></span>
    </div>
    <div class="form-group">
        <input type="submit" value="Create" class="btn btn-default" />
    </div>
    string Models.Movie.Rating { get; set; }
</div>
<div>
    <a asp-page="Index">Back to List</a>
</div>
```

The screenshot shows a portion of the `Create.cshtml` file. A tooltip from the `asp-for` attribute is open, displaying a list of properties for the `Movie` model. The `Rating` property is highlighted in blue, indicating it is the current selection. Other properties listed include `Genre`, `GetHashCode`, `GetType`, `ID`, `Price`, `ReleaseDate`, `Title`, and `ToString`. The `Rating` entry is preceded by a key icon, while the others have a gear icon.

The following code shows `Create.cshtml` with a `Rating` field:

```

@page
@model RazorPagesMovie.Pages.Movies.CreateModel

 @{
     ViewData["Title"] = "Create";
 }

<h2>Create</h2>

<h4>Movie</h4>
<hr />
<div class="row">
    <div class="col-md-4">
        <form method="post">
            <div asp-validation-summary="ModelOnly" class="text-danger"></div>
            <div class="form-group">
                <label asp-for="Movie.Title" class="control-label"></label>
                <input asp-for="Movie.Title" class="form-control" />
                <span asp-validation-for="Movie.Title" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Movie.ReleaseDate" class="control-label"></label>
                <input asp-for="Movie.ReleaseDate" class="form-control" />
                <span asp-validation-for="Movie.ReleaseDate" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Movie.Genre" class="control-label"></label>
                <input asp-for="Movie.Genre" class="form-control" />
                <span asp-validation-for="Movie.Genre" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Movie.Price" class="control-label"></label>
                <input asp-for="Movie.Price" class="form-control" />
                <span asp-validation-for="Movie.Price" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Movie.Rating" class="control-label"></label>
                <input asp-for="Movie.Rating" class="form-control" />
                <span asp-validation-for="Movie.Rating" class="text-danger"></span>
            </div>
            <div class="form-group">
                <input type="submit" value="Create" class="btn btn-default" />
            </div>
        </form>
    </div>
</div>

<div>
    <a asp-page="Index">Back to List</a>
</div>

@section Scripts {
    @await Html.RenderPartialAsync("_ValidationScriptsPartial");
}

```

Add the `Rating` field to the Edit Page.

The app won't work until the DB is updated to include the new field. If run now, the app throws a `SqlException`:

```
SqlException: Invalid column name 'Rating'.
```

This error is caused by the updated Movie model class being different than the schema of the Movie table of the database. (There's no `Rating` column in the database table.)

There are a few approaches to resolving the error:

1. Have the Entity Framework automatically drop and re-create the database using the new model class schema. This approach is convenient early in the development cycle; it allows you to quickly evolve the model and database schema together. The downside is that you lose existing data in the database. You don't want to use this approach on a production database! Dropping the DB on schema changes and using an initializer to automatically seed the database with test data is often a productive way to develop an app.
2. Explicitly modify the schema of the existing database so that it matches the model classes. The advantage of this approach is that you keep your data. You can make this change either manually or by creating a database change script.
3. Use Code First Migrations to update the database schema.

For this tutorial, use Code First Migrations.

Update the `SeedData` class so that it provides a value for the new column. A sample change is shown below, but you'll want to make this change for each `new Movie` block.

```
context.Movie.AddRange(  
    new Movie  
    {  
        Title = "When Harry Met Sally",  
        ReleaseDate = DateTime.Parse("1989-2-12"),  
        Genre = "Romantic Comedy",  
        Price = 7.99M,  
        Rating = "R"  
    },
```

See the [completed SeedData.cs file](#).

See the [completed SeedData.cs file](#).

Build the solution.

From the **Tools** menu, select **NuGet Package Manager > Package Manager Console**. In the PMC, enter the following commands:

```
Add-Migration Rating  
Update-Database
```

The `Add-Migration` command tells the framework to:

- Compare the `Movie` model with the `Movie` DB schema.
- Create code to migrate the DB schema to the new model.

The name "Rating" is arbitrary and is used to name the migration file. It's helpful to use a meaningful name for the migration file.

If you delete all the records in the DB, the initializer will seed the DB and include the `Rating` field. You can do this with the delete links in the browser or from [Sql Server Object Explorer](#) (SSOX). To delete the database from SSOX:

- Select the database in SSOX.
- Right click on the database, and select *Delete*.
- Check **Close existing connections**.

- Select **OK**.
- In the [PMC](#), update the database:

```
Update-Database
```

Run the app and verify you can create/edit/display movies with a [Rating](#) field. If the database isn't seeded, stop IIS Express, and then run the app.

[PREVIOUS: ADDING  
SEARCH](#)

[NEXT: ADDING  
VALIDATION](#)

# Add validation to an ASP.NET Core Razor Page

7/11/2018 • 8 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section, validation logic is added to the `Movie` model. The validation rules are enforced any time a user creates or edits a movie.

## Validation

A key tenet of software development is called **DRY** ("Don't Repeat Yourself"). Razor Pages encourages development where functionality is specified once, and it's reflected throughout the app. DRY can help reduce the amount of code in an app. DRY makes the code less error prone, and easier to test and maintain.

The validation support provided by Razor Pages and Entity Framework is a good example of the DRY principle. Validation rules are declaratively specified in one place (in the model class), and the rules are enforced everywhere in the app.

### Adding validation rules to the movie model

Open the `Movie.cs` file. [DataAnnotations](#) provides a built-in set of validation attributes that are applied declaratively to a class or property. DataAnnotations also contains formatting attributes like `DataType` that help with formatting and don't provide validation.

Update the `Movie` class to take advantage of the `Required`, `StringLength`, `RegularExpression`, and `Range` validation attributes.

```
public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3)]
    [Required]
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [Range(1, 100)]
    [DataType(DataType.Currency)]
    public decimal Price { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z''"\s-]*$")]
    [Required]
    [StringLength(30)]
    public string Genre { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z0-9'''\s-]*$")]
    [StringLength(5)]
    [Required]
    public string Rating { get; set; }
}
```

```

//#define MovieDateRatingDA
#if MovieDateRatingDA
using System;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace RazorPagesMovie.Models
{
    #region snippet1
    public class Movie
    {
        public int ID { get; set; }

        [StringLength(60, MinimumLength = 3)]
        [Required]
        public string Title { get; set; }

        #region snippet2
        [Display(Name = "Release Date")]
        [DataType(DataType.Date)]
        public DateTime ReleaseDate { get; set; }

        [Range(1, 100)]
        [DataType(DataType.Currency)]
        [Column(TypeName = "decimal(18, 2)")]
        public decimal Price { get; set; }
        #endregion

        [RegularExpression(@"^[A-Z]+[a-zA-Z'''\s-]*$")]
        [Required]
        [StringLength(30)]
        public string Genre { get; set; }

        [RegularExpression(@"^[A-Z]+[a-zA-Z0-9'''\s-]*$")]
        [StringLength(5)]
        [Required]
        public string Rating { get; set; }
    }
    #endregion
}
#endif

```

Validation attributes specify behavior that's enforced on model properties:

- The `Required` and `MinimumLength` attributes indicate that a property must have a value. However, nothing prevents a user from entering whitespace to satisfy the validation constraint for a nullable type. Non-nullable `value types` (such as `decimal`, `int`, `float`, and `DateTime`) are inherently required and don't need the `Required` attribute.
- The `RegularExpression` attribute limits the characters that the user can enter. In the preceding code, `Genre` must start with one or more capital letters and follow with zero or more letters, single or double quotes, whitespace characters, or dashes. `Rating` must start with one or more capital letters and follow with zero or more letters, numbers, single or double quotes, whitespace characters, or dashes.
- The `Range` attribute constrains a value to a specified range.
- The `StringLength` attribute sets the maximum length of a string, and optionally the minimum length.

Having validation rules automatically enforced by ASP.NET Core helps make an app more robust. Automatic validation on models helps protect the app because you don't have to remember to apply them when new code is added.

## Validation Error UI in Razor Pages

Run the app and navigate to Pages/Movies.

Select the **Create New** link. Complete the form with some invalid values. When jQuery client-side validation detects the error, it displays an error message.

The screenshot shows a browser window titled "Create - Movie" with the URL "localhost:5000/Movies/Create". The page is titled "RpMovie" and has a "Create" heading. The form contains five fields: "Title" (value "a"), "Release Date" (value "00/01/0001"), "Genre" (value "a"), "Price" (value "Dog"), and "Rating" (value "z"). Below each field is a red validation message: "The field Title must be a string with a minimum length of 3 and a maximum length of 60.", "The Release Date field is required.", "The field Genre must match the regular expression '^([A-Z]+[a-zA-Z"-\'s]\*\$'.", "The field Price must be a number.", and "The field Rating must match the regular expression '^([A-Z]+[a-zA-Z"-\'s]\*\$'. At the bottom are "Create" and "Back to List" buttons.

#### NOTE

You may not be able to enter decimal points or commas in the `Price` field. To support [jQuery validation](#) in non-English locales that use a comma (",") for a decimal point, and non US-English date formats, you must take steps to globalize your app. See [Additional resources](#) for more information. For now, just enter whole numbers like 10.

Notice how the form has automatically rendered a validation error message in each field containing an invalid value. The errors are enforced both client-side (using JavaScript and jQuery) and server-side (when a user has JavaScript disabled).

A significant benefit is that **no** code changes were necessary in the Create or Edit pages. Once DataAnnotations were applied to the model, the validation UI was enabled. The Razor Pages created in this tutorial automatically picked up the validation rules (using validation attributes on the properties of the `Movie` model class). Test validation using the Edit page, the same validation is applied.

The form data isn't posted to the server until there are no client-side validation errors. Verify form data isn't posted by one or more of the following approaches:

- Put a break point in the `OnPostAsync` method. Submit the form (select **Create** or **Save**). The break point is never hit.
- Use the [Fiddler tool](#).
- Use the browser developer tools to monitor network traffic.

## Server-side validation

When JavaScript is disabled in the browser, submitting the form with errors will post to the server.

Optional, test server-side validation:

- Disable JavaScript in the browser. If you can't disable JavaScript in the browser, try another browser.
- Set a break point in the `OnPostAsync` method of the Create or Edit page.
- Submit a form with validation errors.
- Verify the model state is invalid:

```
if (!ModelState.IsValid)
{
    return Page();
}
```

The following code shows a portion of the *Create.cshtml* page that you scaffolded earlier in the tutorial. It's used by the Create and Edit pages to display the initial form and to redisplay the form in the event of an error.

```
<form method="post">
    <div asp-validation-summary="ModelOnly" class="text-danger"></div>
    <div class="form-group">
        <label asp-for="Movie.Title" class="control-label"></label>
        <input asp-for="Movie.Title" class="form-control" />
        <span asp-validation-for="Movie.Title" class="text-danger"></span>
    </div>
```

The [Input Tag Helper](#) uses the [DataAnnotations](#) attributes and produces HTML attributes needed for jQuery Validation on the client-side. The [Validation Tag Helper](#) displays validation errors. See [Validation](#) for more information.

The Create and Edit pages have no validation rules in them. The validation rules and the error strings are specified only in the `Movie` class. These validation rules are automatically applied to Razor Pages that edit the `Movie` model.

When validation logic needs to change, it's done only in the model. Validation is applied consistently throughout the application (validation logic is defined in one place). Validation in one place helps keep the code clean, and makes it easier to maintain and update.

## Using DataType Attributes

Examine the `Movie` class. The `System.ComponentModel.DataAnnotations` namespace provides formatting attributes in addition to the built-in set of validation attributes. The `DataType` attribute is applied to the `ReleaseDate` and `Price` properties.

```
[Display(Name = "Release Date")]
[DataType(DataType.Date)]
public DateTime ReleaseDate { get; set; }

[Range(1, 100)]
[DataType(DataType.Currency)]
public decimal Price { get; set; }
```

The `DataType` attributes only provide hints for the view engine to format the data (and supplies attributes such as `<a>` for URL's and `<a href="mailto:EmailAddress.com">` for email). Use the `RegularExpression` attribute to validate the format of the data. The `DataType` attribute is used to specify a data type that's more specific than the database intrinsic type. `DataType` attributes are not validation attributes. In the sample application, only the date is displayed, without time.

The `DataType` Enumeration provides for many data types, such as Date, Time, PhoneNumber, Currency, EmailAddress, and more. The `DataType` attribute can also enable the application to automatically provide type-specific features. For example, a `mailto:` link can be created for `DataType.EmailAddress`. A date selector can be provided for `DataType.Date` in browsers that support HTML5. The `DataType` attributes emits HTML 5 `data-` (pronounced data dash) attributes that HTML 5 browsers consume. The `DataType` attributes do **not** provide any validation.

`DataType.Date` doesn't specify the format of the date that's displayed. By default, the data field is displayed according to the default formats based on the server's `CultureInfo`.

The `[Column(TypeName = "decimal(18, 2)")]` data annotation is required so Entity Framework Core can correctly map `Price` to currency in the database. For more information, see [Data Types](#).

The `DisplayFormat` attribute is used to explicitly specify the date format:

```
[DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
public DateTime ReleaseDate { get; set; }
```

The `ApplyFormatInEditMode` setting specifies that the formatting should be applied when the value is displayed for editing. You might not want that behavior for some fields. For example, in currency values, you probably don't want the currency symbol in the edit UI.

The `DisplayFormat` attribute can be used by itself, but it's generally a good idea to use the `DataType` attribute. The `DataType` attribute conveys the semantics of the data as opposed to how to render it on a screen, and provides the following benefits that you don't get with `DisplayFormat`:

- The browser can enable HTML5 features (for example to show a calendar control, the locale-appropriate currency symbol, email links, etc.)
- By default, the browser will render data using the correct format based on your locale.
- The `DataType` attribute can enable the ASP.NET Core framework to choose the right field template to render the data. The `DisplayFormat` if used by itself uses the string template.

Note: jQuery validation doesn't work with the `Range` attribute and `DateTime`. For example, the following code will always display a client-side validation error, even when the date is in the specified range:

```
[Range(typeof(DateTime), "1/1/1966", "1/1/2020")]
```

It's generally not a good practice to compile hard dates in your models, so using the `Range` attribute and `DateTime` is discouraged.

The following code shows combining attributes on one line:

```
public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3)]
    public string Title { get; set; }

    [Display(Name = "Release Date"), DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z\s-]*$"), Required, StringLength(30)]
    public string Genre { get; set; }

    [Range(1, 100), DataType(DataType.Currency)]
    public decimal Price { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z0-9\s-]*$"), StringLength(5)]
    public string Rating { get; set; }
}
```

```
public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3)]
    public string Title { get; set; }

    [Display(Name = "Release Date"), DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z\s-]*$"), Required, StringLength(30)]
    public string Genre { get; set; }

    [Range(1, 100), DataType(DataType.Currency)]
    [Column(TypeName = "decimal(18, 2)")]
    public decimal Price { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z0-9\s-]*$"), StringLength(5)]
    public string Rating { get; set; }
}
```

[Get started with Razor Pages and EF Core](#) shows advanced EF Core operations with Razor Pages.

## Publish to Azure

See [Publish an ASP.NET Core web app to Azure App Service using Visual Studio](#) for instructions on how to publish this app to Azure.

Thanks for completing this introduction to Razor Pages. We appreciate feedback. [Get started with MVC and EF Core](#) is an excellent follow up to this tutorial.

[FIELD](#)

# Get started with SignalR on ASP.NET Core

7/5/2018 • 5 minutes to read • [Edit Online](#)

By [Rachel Appel](#)

This tutorial teaches the basics of building a real-time app using SignalR for ASP.NET Core.

The image contains two side-by-side screenshots of a web browser displaying a SignalR-based chat application. Both screenshots show the same interface with a dark header bar containing the text "SignalRChat". Below the header is a form with two input fields: "Name" and "Message", and a "Send" button. The "Name" field is populated with "Bill Gates" in the top screenshot and "Satya Nadella" in the bottom screenshot. The "Message" field contains the text "Hello, computers!" in both cases. The "Send" button is grayed out in both screenshots. Below the form, a list of messages is displayed in a scrollable area. In the top screenshot, the messages are:

- 3/15/2018 11:12:10 PM **Bill Gates**: Hello, computers!
- 3/15/2018 11:12:29 PM **Satya Nadella**: Hello, cloud computers!

In the bottom screenshot, the messages are:

- 3/15/2018 11:12:10 PM **Bill Gates**: Hello, computers!
- 3/15/2018 11:12:29 PM **Satya Nadella**: Hello, cloud computers!

At the bottom of each screenshot, there is a copyright notice: "© 2018 - SignalRChat".

This tutorial demonstrates the following SignalR development tasks:

- Create a SignalR on ASP.NET Core web app.
- Create a SignalR hub to push content to clients.
- Modify the `Startup` class and configure the app.

[View or download sample code](#) ([how to download](#))

## Prerequisites

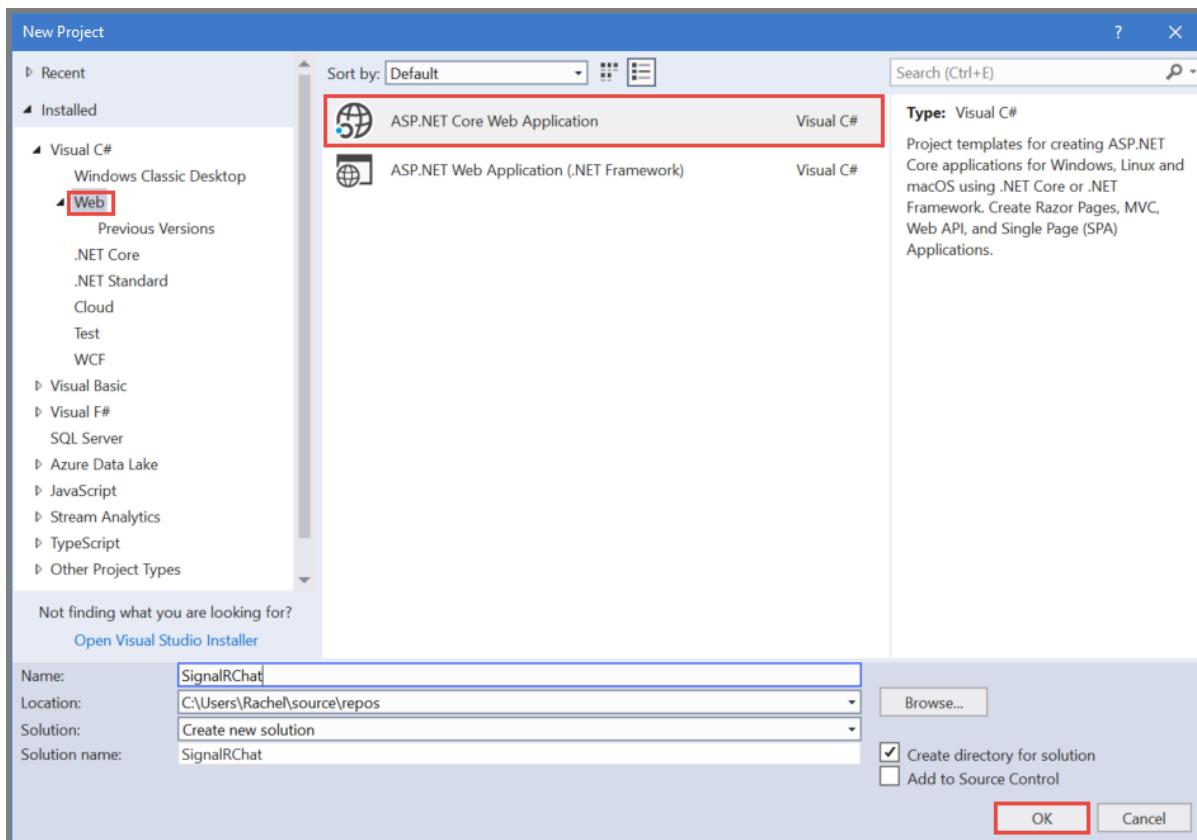

Install the following software:

- [Visual Studio](#)
- [Visual Studio Code](#)
- [.NET Core SDK 2.1 or later](#)
- [Visual Studio 2017](#) version 15.7.3 or later with the **ASP.NET and web development** workload
- [npm](#)

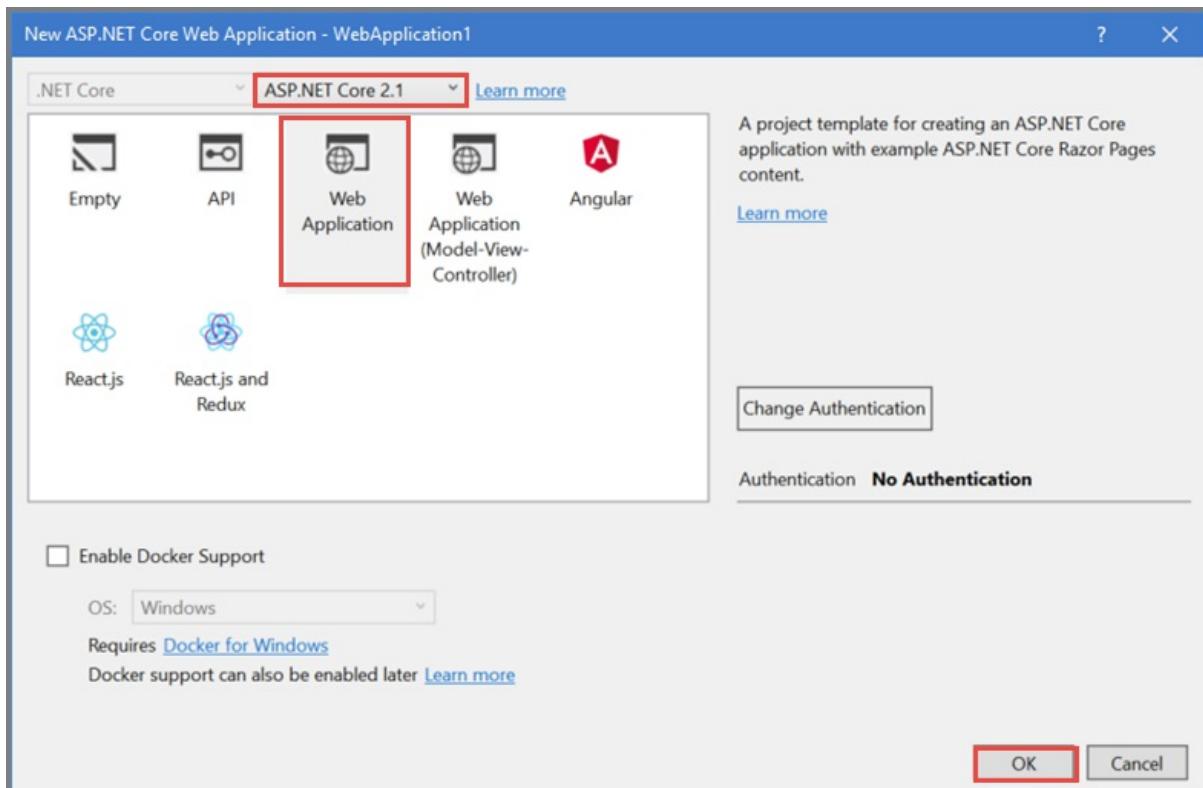

## Create an ASP.NET Core project that hosts SignalR client and server

- [Visual Studio](#)
- [Visual Studio Code](#)

1. Use the **File > New Project** menu option and choose **ASP.NET Core Web Application**. Name the project *SignalRChat*.

2. Select **Web Application** to create a project using Razor Pages. Then select **OK**. Be sure that **ASP.NET Core 2.1** is selected from the framework selector, though SignalR runs on older versions of .NET.

Visual Studio includes the `Microsoft.AspNetCore.SignalR` package containing its server libraries as part of its **ASP.NET Core Web Application** template. However, the JavaScript client library for SignalR must be installed using *npm*.

3. Run the following commands in the **Package Manager Console** window, from the project root:

```
npm init -y
npm install @aspnet/signalr
```

4. Create a new folder named "signalr" inside the *lib* folder in your project. Copy the *signalrjs* file from *node\_modules\@aspnet\signalr\dist\browser* to this folder.

## Create the SignalR Hub

A hub is a class that serves as a high-level pipeline that allows the client and server to call methods on each other.

- [Visual Studio](#)
- [Visual Studio Code](#)

1. Add a class to the project by choosing **File > New > File** and selecting **Visual C# Class**. Name the class `ChatHub` and the file `ChatHub.cs`.
2. Inherit from `Microsoft.AspNetCore.SignalR.Hub`. The `Hub` class contains properties and events for managing connections and groups, as well as sending and receiving data.
3. Create the `SendMessage` method that sends a message to all connected chat clients. Notice it returns a `Task`, because SignalR is asynchronous. Asynchronous code scales better.

```
using Microsoft.AspNetCore.SignalR;
using System.Threading.Tasks;

namespace SignalRChat.Hubs
{
    public class ChatHub : Hub
    {
        public async Task SendMessage(string user, string message)
        {
            await Clients.All.SendAsync("ReceiveMessage", user, message);
        }
    }
}
```

## Configure the project to use SignalR

The SignalR server must be configured so that it knows to pass requests to SignalR.

1. To configure a SignalR project, modify the project's `Startup.ConfigureServices` method.

`services.AddSignalR` makes the SignalR services available to the [dependency injection](#) system.

2. Configure routes to your hubs with `UseSignalR` in the `Configure` method. `app.UseSignalR` adds SignalR to the [middleware](#) pipeline.

```
using Microsoft.AspNetCore.Builder;
using Microsoft.AspNetCore.Hosting;
using Microsoft.AspNetCore.Http;
using Microsoft.Extensions.Configuration;
using Microsoft.Extensions.DependencyInjection;
using SignalRChat.Hubs;

namespace SignalRChat
{
    public class Startup
    {
        public Startup(IConfiguration configuration)
        {
            Configuration = configuration;
        }

        public IConfiguration Configuration { get; }

        public void ConfigureServices(IServiceCollection services)
        {
            services.Configure<CookiePolicyOptions>(options =>
            {
                options.CheckConsentNeeded = context => true;
                options.MinimumSameSitePolicy = SameSiteMode.None;
            });

            services.AddMvc();

            services.AddCors(options => options.AddPolicy("CorsPolicy",
                builder =>
                {
                    builder.AllowAnyMethod().AllowAnyHeader()
                        .WithOrigins("http://localhost:55830")
                        .AllowCredentials();
                }));
            services.AddSignalR();
        }

        public void Configure(IApplicationBuilder app, IHostingEnvironment env)
        {
            if (env.IsDevelopment())
            {

                app.UseDeveloperExceptionPage();
            }
            else
            {
                app.UseExceptionHandler("/Error");
                app.UseHsts();
            }

            app.UseHttpsRedirection();
            app.UseStaticFiles();
            app.UseCookiePolicy();
            app.UseCors("CorsPolicy");
            app.UseSignalR(routes =>
            {
                routes.MapHub<ChatHub>("/chatHub");
            });
            app.UseMvc();
        }
    }
}
```

## Create the SignalR client code

1. Add a JavaScript file, named *chat.js*, to the *wwwroot\js* folder. Add the following code to it:

```
// The following sample code uses modern ECMAScript 6 features
// that aren't supported in Internet Explorer 11.
// To convert the sample for environments that do not support ECMAScript 6,
// such as Internet Explorer 11, use a transpiler such as
// Babel at http://babeljs.io/.
//
// See Es5-chat.js for a Babel transpiled version of the following code:

const connection = new signalR.HubConnectionBuilder()
    .withUrl("/chatHub")
    .build();

connection.on("ReceiveMessage", (user, message) => {
    const msg = message.replace(/&/g, "&").replace(/</g, "<").replace(/>/g, ">");
    const encodedMsg = user + " says " + msg;
    const li = document.createElement("li");
    li.textContent = encodedMsg;
    document.getElementById("messagesList").appendChild(li);
});

connection.start().catch(err => console.error(err.toString()));

document.getElementById("sendButton").addEventListener("click", event => {
    const user = document.getElementById("userInput").value;
    const message = document.getElementById("messageInput").value;
    connection.invoke("SendMessage", user, message).catch(err => console.error(err.toString()));
    event.preventDefault();
});
```

2. Replace the content in *Pages\Index.cshtml* with the following code:

```
@page

<div class="row">&nbsp;</div>
    <div class="row">
        <div class="col-6">&nbsp;</div>
        <div class="col-6">
            User.....<input type="text" id="userInput" />
            <br />
            Message...<input type="text" id="messageInput" />
            <input type="button" id="sendButton" value="Send Message" />
        </div>
    </div>
    <div class="row">
        <div class="col-12">
            <hr />
        </div>
    </div>
    <div class="row">
        <div class="col-6">&nbsp;</div>
        <div class="col-6">
            <ul id="messagesList"></ul>
        </div>
    </div>
</div>
<script src="~/lib/signalr/signalr.js"></script>
<script src="~/js/chat.js"></script>
@*<script src="~/js/es5-chat.js"></script>*@

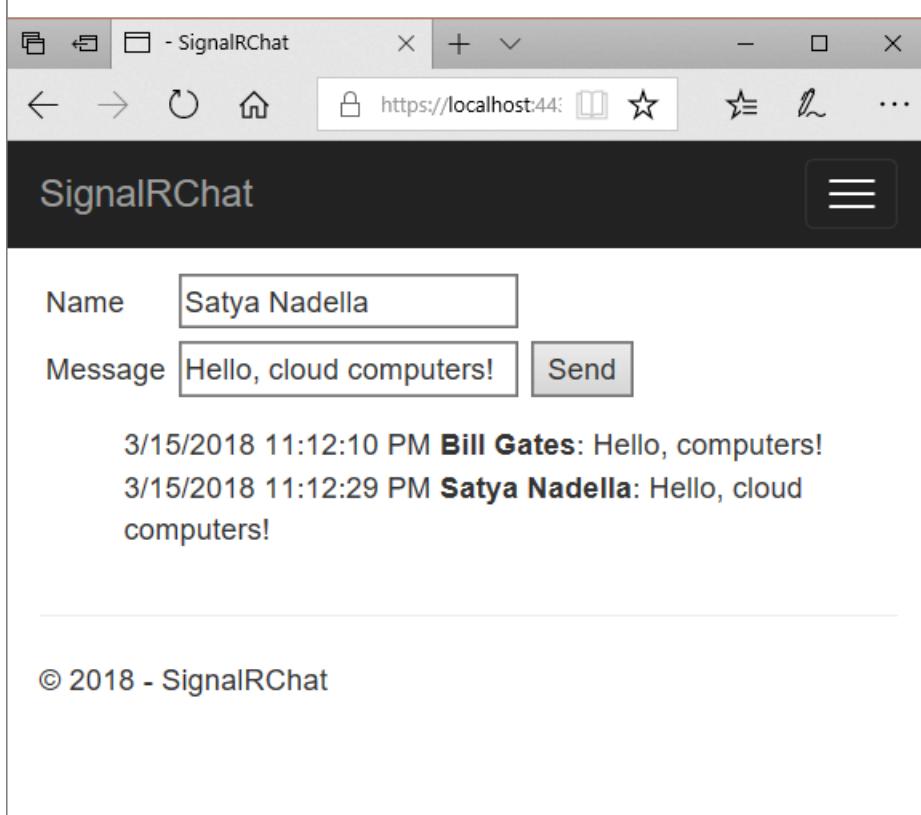

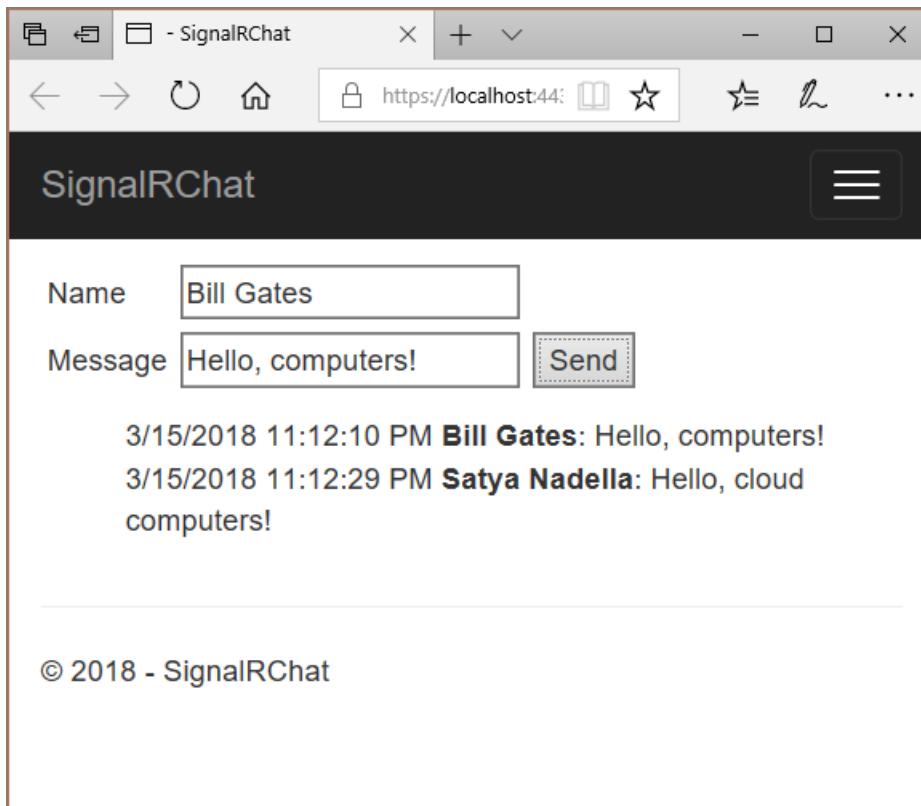

```

The preceding HTML displays name and message fields, and a submit button. Notice the script references at the bottom: a reference to SignalR and *chat.js*.

## Run the app

- [Visual Studio](#)
- [Visual Studio Code](#)

1. Select **Debug > Start without debugging** to launch a browser and load the website locally. Copy the URL from the address bar.
2. Open another browser instance (any browser) and paste the URL in the address bar.
3. Choose either browser, enter a name and message, and click the **Send** button. The name and message are displayed on both pages instantly.

[Introduction to ASP.NET Core SignalR](#)

# Use ASP.NET Core SignalR with TypeScript and Webpack

7/10/2018 • 10 minutes to read • [Edit Online](#)

By Sébastien Sougnez and Scott Addie

Webpack enables developers to bundle and build the client-side resources of a web app. This tutorial demonstrates using Webpack in an ASP.NET Core SignalR web app whose client is written in [TypeScript](#).

In this tutorial, you learn how to:

- Scaffold a starter ASP.NET Core SignalR app
- Configure the SignalR TypeScript client
- Configure a build pipeline using Webpack
- Configure the SignalR server
- Enable communication between client and server

[View or download sample code \(how to download\)](#)

## Prerequisites

Install the following software:

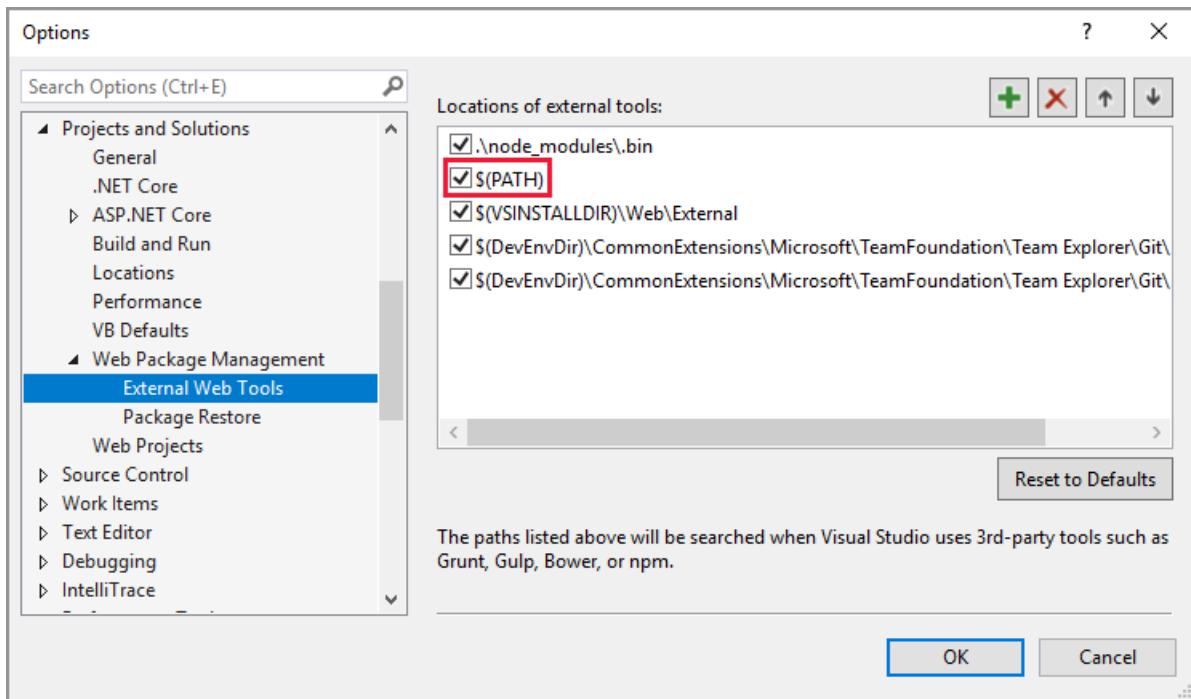

- [Visual Studio](#)
- [.NET Core CLI](#)
- [.NET Core SDK 2.1 or later](#)
- [Node.js](#) with [npm](#)
- [Visual Studio 2017](#) version 15.7.3 or later with the **ASP.NET and web development** workload

## Create the ASP.NET Core web app

- [Visual Studio](#)
- [.NET Core CLI](#)

Configure Visual Studio to look for npm in the *PATH* environment variable. By default, Visual Studio uses the version of npm found in its installation directory. Follow these instructions in Visual Studio:

1. Navigate to **Tools > Options > Projects and solutions > Web Package Management > External Web Tools**.
2. Select the `$(PATH)` entry from the list. Click the up arrow to move the entry to the second position in the list.  
As an aside, the first entry refers to the project's local packages.

Visual Studio configuration is completed. It's time to create the project.

1. Use the **File > New > Project** menu option and choose the **ASP.NET Core Web Application** template.
2. Name the project *SignalRWebPack*, and click the **OK** button.
3. Select *.NET Core* from the target framework drop-down, and select *ASP.NET Core 2.1* from the framework selector drop-down. Select the **Empty** template, and click the **OK** button.

## Configure Webpack and TypeScript

The following steps configure the conversion of TypeScript to JavaScript and the bundling of client-side resources.

1. Execute the following command in the project root to create a *package.json* file:

```
npm init -y
```

2. Add the highlighted property to the *package.json* file:

```
{
  "name": "SignalRWebPack",
  "version": "1.0.0",
  "private": true,
  "description": "",
  "main": "index.js",
  "scripts": {
    "test": "echo \"Error: no test specified\" && exit 1"
  },
  "keywords": [],
  "author": "",
  "license": "ISC"
}
```

Setting the `private` property to `true` prevents package installation warnings in the next step.

3. Install the required npm packages. Execute the following command from the project root:

```
npm install -D -E clean-webpack-plugin@0.1.19 css-loader@0.28.11 html-webpack-plugin@3.2.0 mini-css-extract-plugin@0.4.0 ts-loader@4.4.1 typescript@2.9.2 webpack@4.12.0 webpack-cli@3.0.6
```

Some command details to note:

- A version number follows the `@` sign for each package name. npm installs those specific package versions.
- The `-E` option disables npm's default behavior of writing [semantic versioning](#) range operators to `package.json`. For example, `"webpack": "4.12.0"` is used instead of `"webpack": "^4.12.0"`. This option prevents unintended upgrades to newer package versions.

See the official [npm-install](#) docs for more detail.

#### 4. Replace the `scripts` property of the `package.json` file with the following snippet:

```
"scripts": {  
  "build": "webpack --mode=development --watch",  
  "release": "webpack --mode=production",  
  "publish": "npm run release && dotnet publish -c Release"  
},
```

Some explanation of the scripts:

- `build` : Bundles your client-side resources in development mode and watches for file changes. The file watcher causes the bundle to regenerate each time a project file changes. The `mode` option disables production optimizations, such as tree shaking and minification. Only use `build` in development.
- `release` : Bundles your client-side resources in production mode.
- `publish` : Runs the `release` script to bundle the client-side resources in production mode. It calls the .NET Core CLI's `publish` command to publish the app.

#### 5. Create a file named `webpack.config.js`, in the project root, with the following content:

```

const path = require("path");
const HtmlWebpackPlugin = require("html-webpack-plugin");
const CleanWebpackPlugin = require("clean-webpack-plugin");
const MiniCssExtractPlugin = require("mini-css-extract-plugin");

module.exports = {
  entry: "./src/index.ts",
  output: {
    path: path.resolve(__dirname, "wwwroot"),
    filename: "[name].[chunkhash].js",
    publicPath: "/"
  },
  resolve: {
    extensions: [".js", ".ts"]
  },
  module: {
    rules: [
      {
        test: /\.ts$/,
        use: "ts-loader"
      },
      {
        test: /\.css$/,
        use: [MiniCssExtractPlugin.loader, "css-loader"]
      }
    ]
  },
  plugins: [
    new CleanWebpackPlugin(["wwwroot/*"]),
    new HtmlWebpackPlugin({
      template: "./src/index.html"
    }),
    new MiniCssExtractPlugin({
      filename: "css/[name].[chunkhash].css"
    })
  ]
};

```

The preceding file configures the Webpack compilation. Some configuration details to note:

- The `output` property overrides the default value of `dist`. The bundle is instead emitted in the `wwwroot` directory.
- The `resolve.extensions` array includes `.js` to import the SignalR client JavaScript.

6. Create a new `src` directory in the project root. Its purpose is to store the project's client-side assets.

7. Create `src/index.html` with the following content.

```

<!DOCTYPE html>
<html>
<head>
  <meta charset="utf-8" />
  <title>ASP.NET Core SignalR</title>
</head>
<body>
  <div id="divMessages" class="messages">
  </div>
  <div class="input-zone">
    <label id="lblMessage" for="tbMessage">Message:</label>
    <input id="tbMessage" class="input-zone-input" type="text" />
    <button id="btnSend">Send</button>
  </div>
</body>
</html>

```

The preceding HTML defines the homepage's boilerplate markup.

8. Create a new `src/css` directory. Its purpose is to store the project's `.css` files.

9. Create `src/css/main.css` with the following content:

```
* { *::before, *::after {  
    box-sizing: border-box;  
}  
  
html, body {  
    margin: 0;  
    padding: 0;  
}  
  
.input-zone {  
    align-items: center;  
    display: flex;  
    flex-direction: row;  
    margin: 10px;  
}  
  
.input-zone-input {  
    flex: 1;  
    margin-right: 10px;  
}  
  
.message-author {  
    font-weight: bold;  
}  
  
.messages {  
    border: 1px solid #000;  
    margin: 10px;  
    max-height: 300px;  
    min-height: 300px;  
    overflow-y: auto;  
    padding: 5px;  
}
```

The preceding `main.css` file styles the app.

10. Create `src/tsconfig.json` with the following content:

```
{  
  "compilerOptions": {  
    "target": "es5"  
  }  
}
```

The preceding code configures the TypeScript compiler to produce [ECMAScript](#) 5-compatible JavaScript.

11. Create `src/index.ts` with the following content:

```

import "./css/main.css";

const divMessages: HTMLDivElement = document.querySelector("#divMessages");
const tbMessage: HTMLInputElement = document.querySelector("#tbMessage");
const btnSend: HTMLButtonElement = document.querySelector("#btnSend");
const username = new Date().getTime();

tbMessage.addEventListener("keyup", (e: KeyboardEvent) => {
    if (e.keyCode === 13) {
        send();
    }
});

btnSend.addEventListener("click", send);

function send() {
}

```

The preceding TypeScript retrieves references to DOM elements and attaches two event handlers:

- `keyup` : This event fires when the user types something in the textbox identified as `tbMessage`. The `send` function is called when the user presses the **Enter** key.
- `click` : This event fires when the user clicks the **Send** button. The `send` function is called.

## Configure the ASP.NET Core app

1. The code provided in the `Startup.Configure` method displays *Hello World!*. Replace the `app.Run` method call with calls to `UseDefaultFiles` and `UseStaticFiles`.

```

app.UseDefaultFiles();
app.UseStaticFiles();

```

The preceding code allows the server to locate and serve the *index.html* file, whether the user enters its full URL or the root URL of the web app.

2. Call `AddSignalR` in the `Startup.ConfigureServices` method. It adds the SignalR services to your project.

```

services.AddSignalR();

```

3. Map a `/hub` route to the `ChatHub` hub. Add the following lines at the end of the `Startup.Configure` method:

```

app.UseSignalR(options =>
{
    options.MapHub<ChatHub>("/hub");
});

```

4. Create a new directory, called *Hubs*, in the project root. Its purpose is to store the SignalR hub, which is created in the next step.
5. Create hub *Hubs/ChatHub.cs* with the following code:

```
using Microsoft.AspNetCore.SignalR;
using System.Threading.Tasks;

namespace SignalRWebPack.Hubs
{
    public class ChatHub : Hub
    {
    }
}
```

6. Add the following code at the top of the *Startup.cs* file to resolve the `ChatHub` reference:

```
using SignalRWebPack.Hubs;
```

## Enable client and server communication

The app currently displays a simple form to send messages. Nothing happens when you try to do so. The server is listening to a specific route but does nothing with sent messages.

1. Execute the following command at the project root:

```
npm install @aspnet/signalr
```

The preceding command installs the [SignalR TypeScript client](#), which allows the client to send messages to the server.

2. Add the highlighted code to the *src/index.ts* file:

```

import "./css/main.css";
import * as signalR from "@aspnet/signalr";

const divMessages: HTMLDivElement = document.querySelector("#divMessages");
const tbMessage: HTMLInputElement = document.querySelector("#tbMessage");
const btnSend: HTMLButtonElement = document.querySelector("#btnSend");
const username = new Date().getTime();

const connection = new signalR.HubConnectionBuilder()
    .withUrl("/hub")
    .build();

connection.start().catch(err => document.write(err));

connection.on("messageReceived", (username: string, message: string) => {
    let m = document.createElement("div");

    m.innerHTML =
        `<div class="message__author">${username}</div><div>${message}</div>`;

    divMessages.appendChild(m);
    divMessages.scrollTop = divMessages.scrollHeight;
});

tbMessage.addEventListener("keyup", (e: KeyboardEvent) => {
    if (e.keyCode === 13) {
        send();
    }
});

btnSend.addEventListener("click", send);

function send() {
}

```

The preceding code supports receiving messages from the server. The `HubConnectionBuilder` class creates a new builder for configuring the server connection. The `withUrl` function configures the hub URL.

SignalR enables the exchange of messages between a client and a server. Each message has a specific name. For example, you can have messages with the name `messageReceived` that execute the logic responsible for displaying the new message in the messages zone. Listening to a specific message can be done via the `on` function. You can listen to any number of message names. It's also possible to pass parameters to the message, such as the author's name and the content of the message received. Once the client receives a message, a new `div` element is created with the author's name and the message content in its `innerHTML` attribute. It's added to the main `div` element displaying the messages.

- Now that the client can receive a message, configure it to send messages. Add the highlighted code to the `src/index.ts` file:

```

import "./css/main.css";
import * as signalR from "@aspnet/signalr";

const divMessages: HTMLDivElement = document.querySelector("#divMessages");
const tbMessage: HTMLInputElement = document.querySelector("#tbMessage");
const btnSend: HTMLButtonElement = document.querySelector("#btnSend");
const username = new Date().getTime();

const connection = new signalR.HubConnectionBuilder()
    .withUrl("/hub")
    .build();

connection.start().catch(err => document.write(err));

connection.on("messageReceived", (username: string, message: string) => {
    let messageContainer = document.createElement("div");

    messageContainer.innerHTML =
        `<div class="message-author">${username}</div><div>${message}</div>`;

    divMessages.appendChild(messageContainer);
    divMessages.scrollTop = divMessages.scrollHeight;
});

tbMessage.addEventListener("keyup", (e: KeyboardEvent) => {
    if (e.keyCode === 13) {
        send();
    }
});

btnSend.addEventListener("click", send);

function send() {
    connection.send("newMessage", username, tbMessage.value)
        .then(() => tbMessage.value = "");
}

```

Sending a message through the WebSockets connection requires calling the `send` method. The method's first parameter is the message name. The message data inhabits the other parameters. In this example, a message identified as `newMessage` is sent to the server. The message consists of the username and the user input from a text box. If the send works, the text box value is cleared.

4. Add the highlighted method to the `ChatHub` class:

```

using Microsoft.AspNetCore.SignalR;
using System.Threading.Tasks;

namespace SignalRWebPack.Hubs
{
    public class ChatHub : Hub
    {
        public async Task NewMessage(string username, string message)
        {
            await Clients.All.SendAsync("messageReceived", username, message);
        }
    }
}

```

The preceding code broadcasts received messages to all connected users once the server receives them. It's unnecessary to have a generic `on` method to receive all the messages. A method named after the message name suffices.

In this example, the TypeScript client sends a message identified as `newMessage`. The C# `NewMessage` method

expects the data sent by the client. A call is made to the `SendAsync` method on `Clients.All`. The received messages are sent to all clients connected to the hub.

## Test the app

Confirm that the app works with the following steps.

- [Visual Studio](#)
- [.NET Core CLI](#)

1. Run Webpack in *release* mode. Using the **Package Manager Console** window, execute the following command in the project root:

```
npm run release
```

This command yields the client-side assets to be served when running the app. The assets are placed in the `wwwroot` folder.

Webpack completed the following tasks:

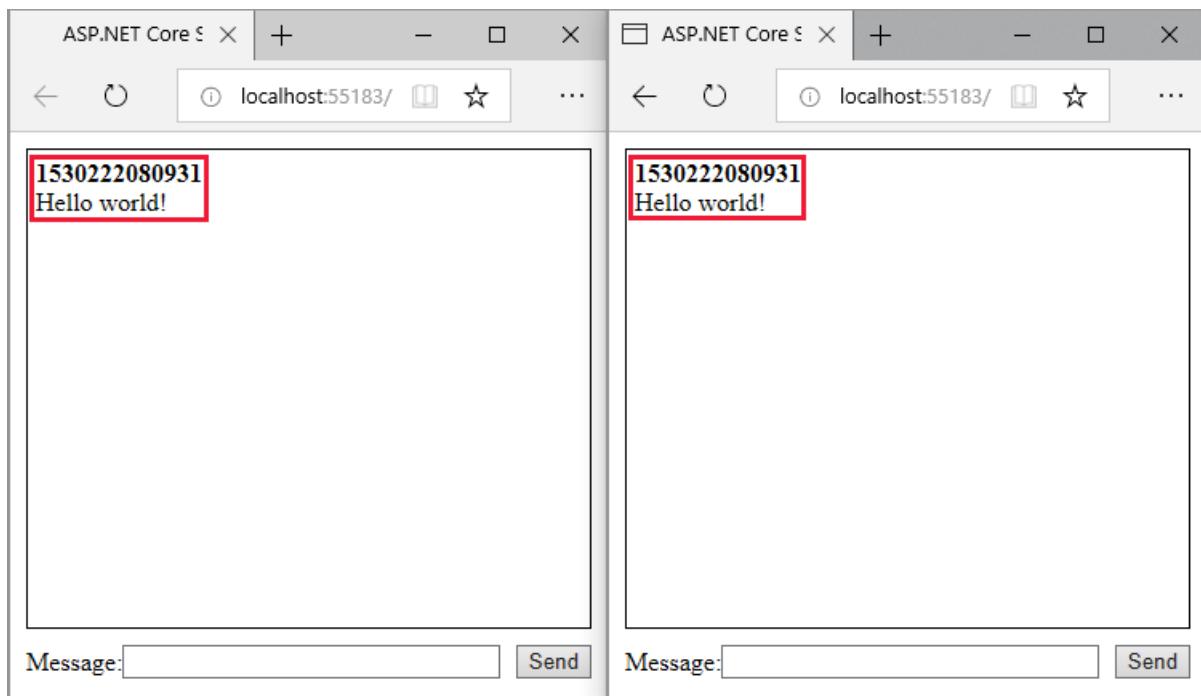

- Purged the contents of the `wwwroot` directory.
- Converted the TypeScript to JavaScript—a process known as *transpilation*.
- Mangled the generated JavaScript to reduce file size—a process known as *minification*.
- Copied the processed JavaScript, CSS, and HTML files from `src` to the `wwwroot` directory.
- Injected the following elements into the `wwwroot/index.html` file:
  - A `<link>` tag, referencing the `wwwroot/main.<hash>.css` file. This tag is placed immediately before the closing `</head>` tag.
  - A `<script>` tag, referencing the minified `wwwroot/main.<hash>.js` file. This tag is placed immediately before the closing `</body>` tag.

2. Select **Debug > Start without debugging** to launch the app in a browser without attaching the debugger.

The `wwwroot/index.html` file is served at `http://localhost:<port_number>`.

3. Open another browser instance (any browser). Paste the URL in the address bar.

4. Choose either browser, type something in the **Message** text box, and click the **Send** button. The unique user name and message are displayed on both pages instantly.

- macOS, Linux, and Windows: [Create an ASP.NET Core MVC app with Visual Studio Code](#)

## Install Visual Studio and .NET Core

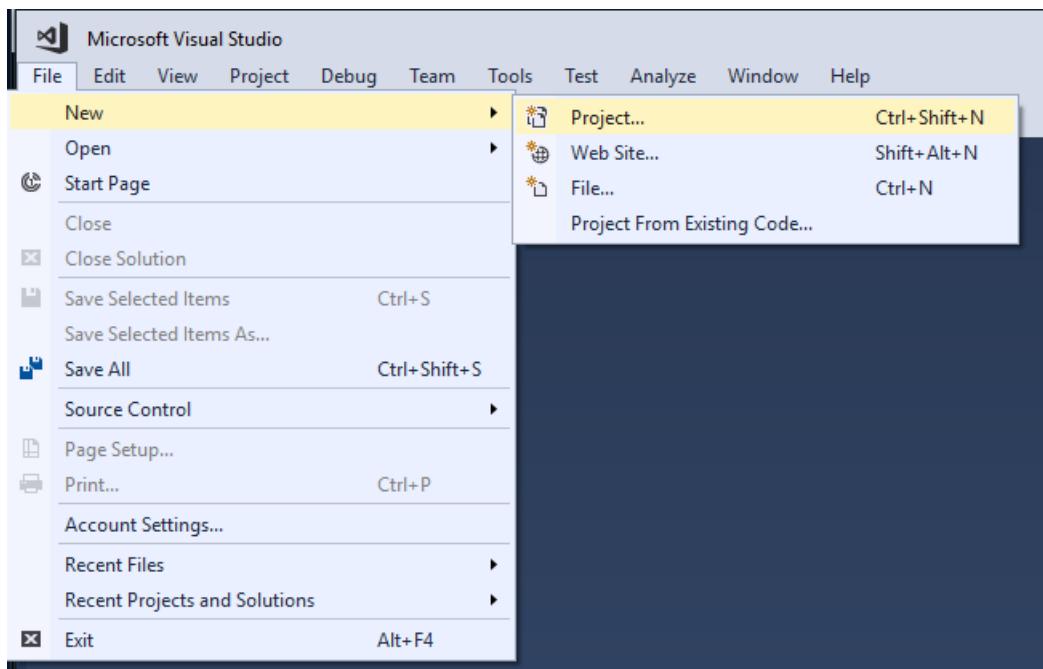

[Visual Studio 2017 version 15.7.3 or later](#) with the following workloads:

- **ASP.NET and web development**
- **.NET Core cross-platform development**

[.NET Core 2.1 SDK or later](#)

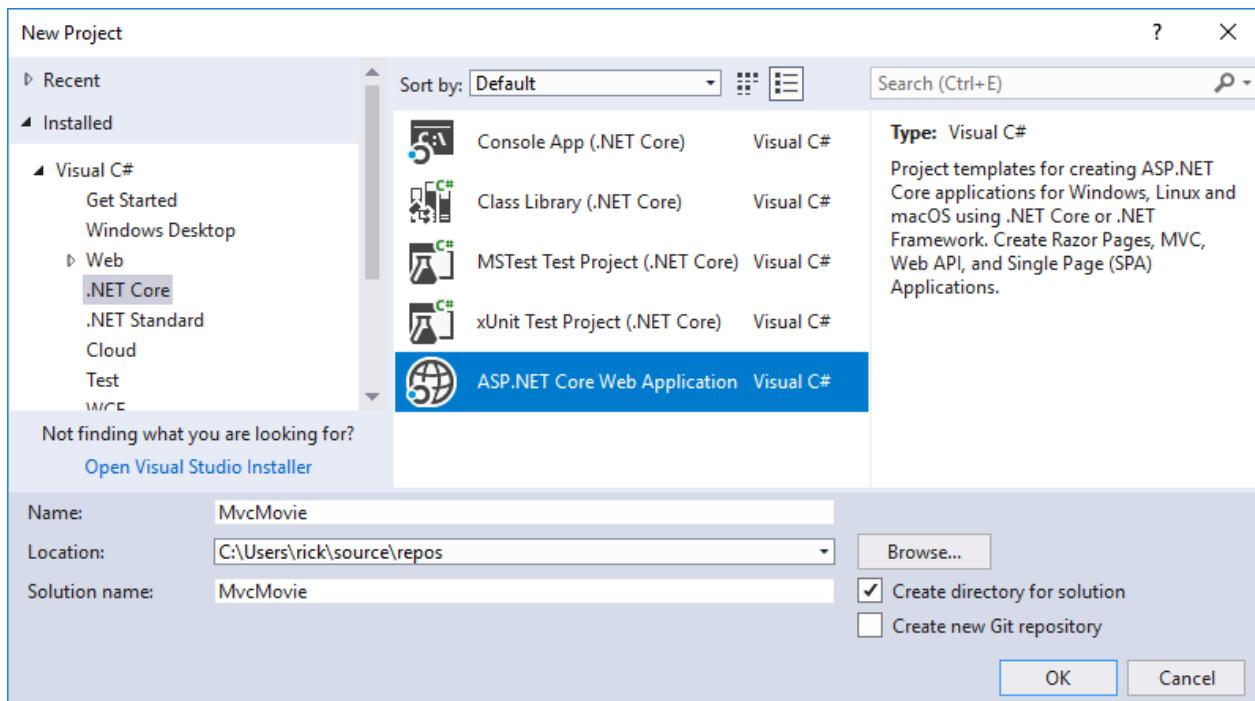

## Create a web app

From Visual Studio, select **File > New > Project**.

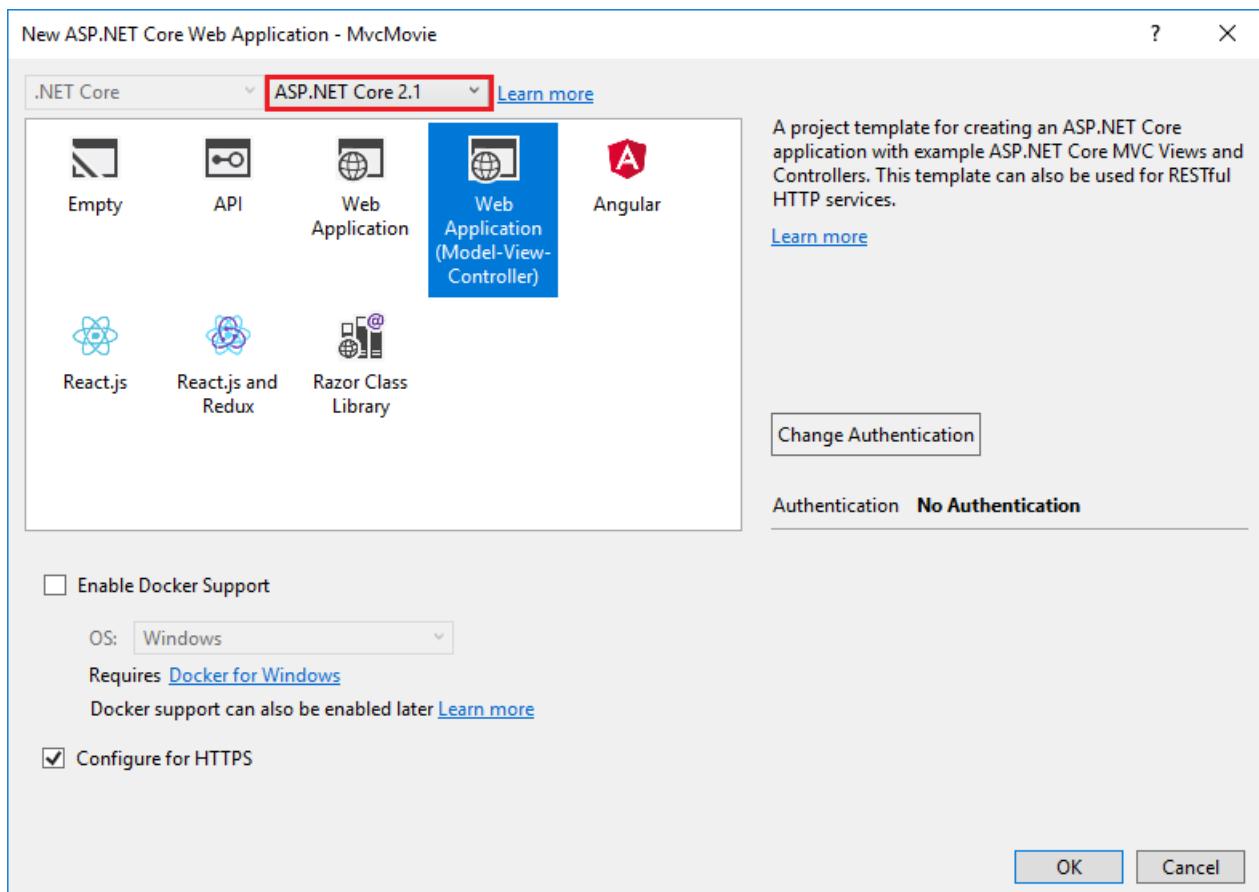

Complete the **New Project** dialog:

- In the left pane, tap **.NET Core**
- In the center pane, tap **ASP.NET Core Web Application (.NET Core)**
- Name the project "MvcMovie" (It's important to name the project "MvcMovie" so when you copy code, the namespace will match.)
- Tap **OK**

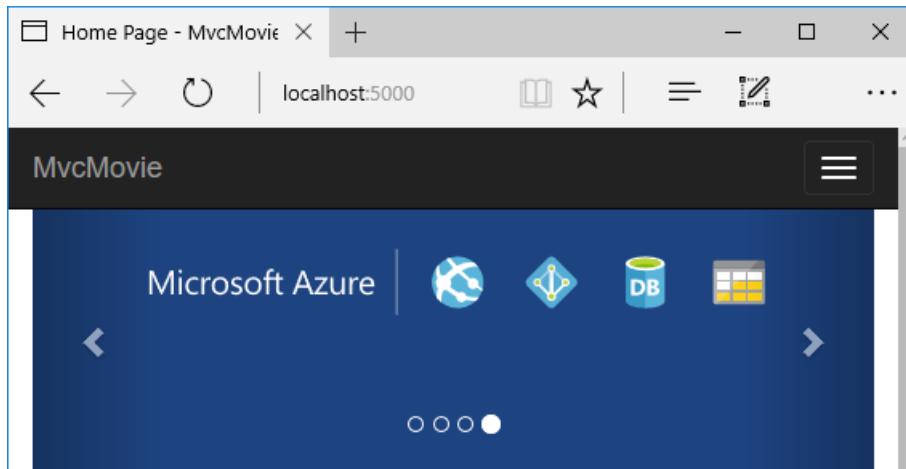

Complete the **New ASP.NET Core Web Application (.NET Core) - MvcMovie** dialog:

- In the version selector drop-down box select **ASP.NET Core 2.1**
- Select **Web Application(Model-View-Controller)**
- Tap **OK**.

Visual Studio used a default template for the MVC project you just created. You have a working app right now by entering a project name and selecting a few options. This is a basic starter project, and it's a good place to start,

Tap **F5** to run the app in debug mode or **Ctrl-F5** in non-debug mode.

## Application uses

- Sample pages using ASP.NET Core MVC
- Bower for managing client-side libraries
- Theming using Bootstrap

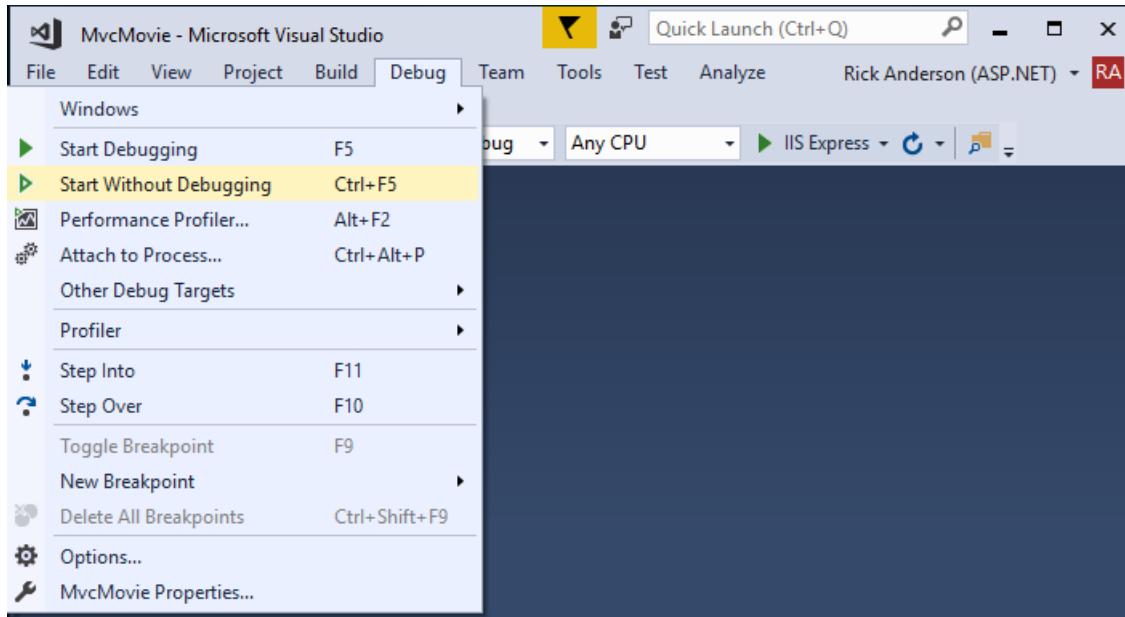

## How to

- Add a Controller and View
- Manage User Secrets using Secret Manager.
- Use logging to log a message.
- Add packages using NuGet

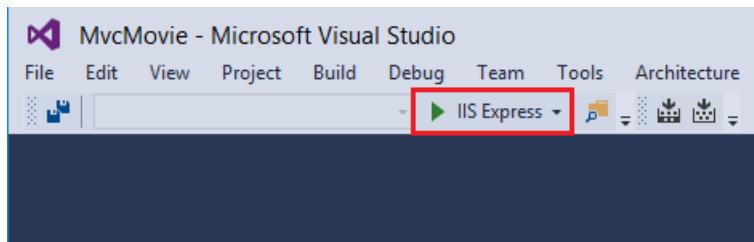

- Visual Studio starts **IIS Express** and runs your app. Notice that the address bar shows `localhost:port#` and not something like `example.com`. That's because `localhost` is the standard hostname for your local computer.

When Visual Studio creates a web project, a random port is used for the web server. In the image above, the port number is 5000. The URL in the browser shows `localhost:5000`. When you run the app, you'll see a different port number.

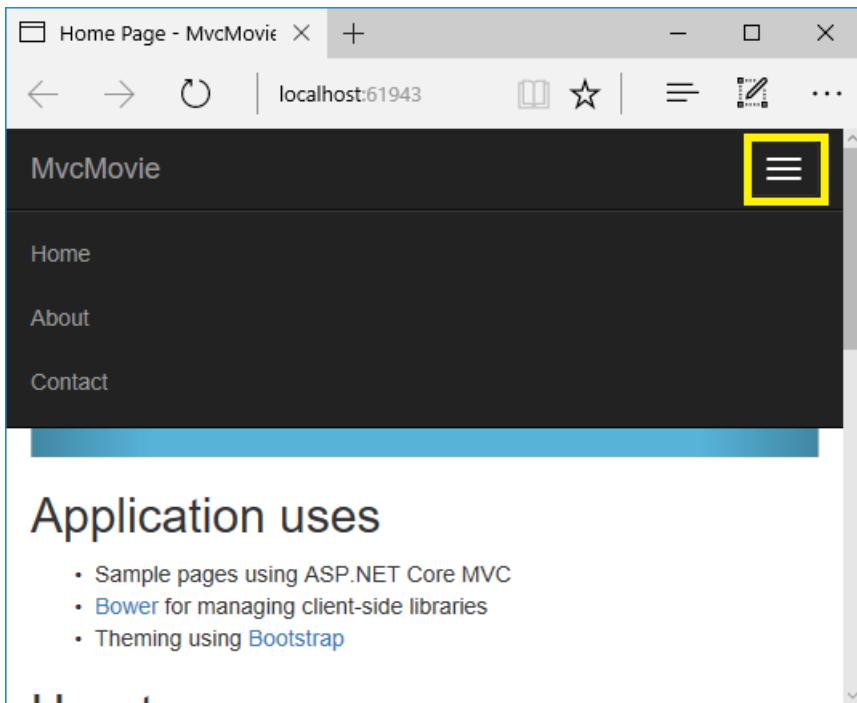

- Launching the app with **Ctrl+F5** (non-debug mode) allows you to make code changes, save the file, refresh the browser, and see the code changes. Many developers prefer to use non-debug mode to quickly launch the app and view changes.
- You can launch the app in debug or non-debug mode from the **Debug** menu item:

- You can debug the app by tapping the **IIS Express** button

The default template gives you working **Home**, **About** and **Contact** links. The browser image above doesn't show these links. Depending on the size of your browser, you might need to click the navigation icon to show them.

If you were running in debug mode, tap **Shift-F5** to stop debugging.

In the next part of this tutorial, we'll learn about MVC and start writing some code.

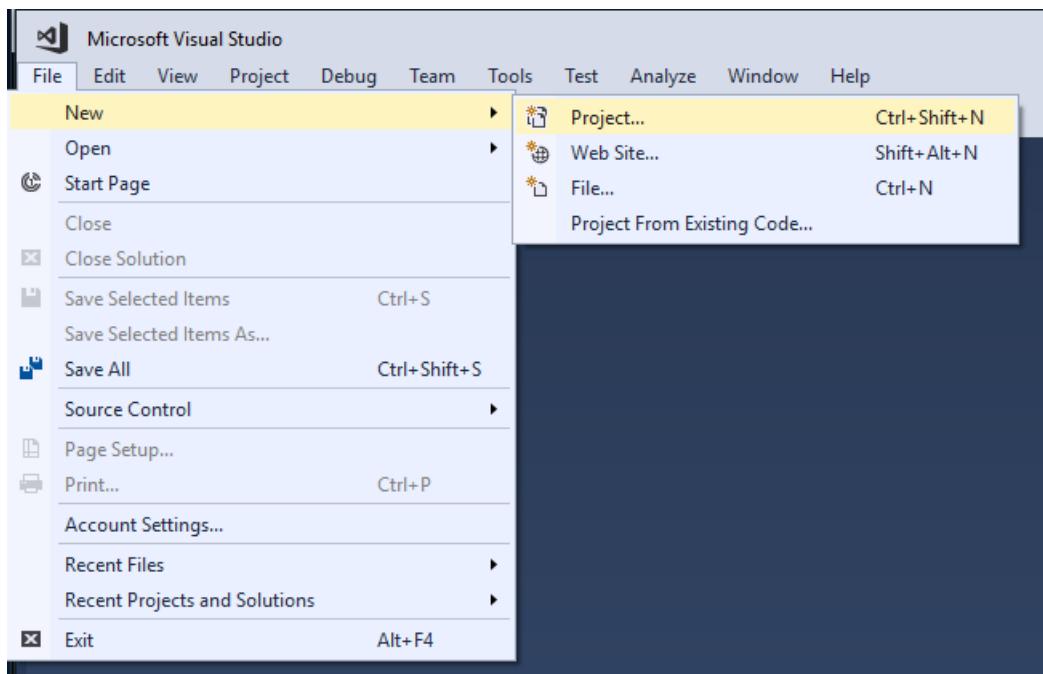

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

Install **one** of the following:

- CLI tooling: Windows, Linux, or macOS: [.NET Core SDK 2.0 or later](#)
- IDE/editor tooling
  - Windows: [Visual Studio for Windows](#)
    - **ASP.NET and web development** workload
    - **.NET Core cross-platform development** workload
  - Linux: [Visual Studio Code](#)
  - macOS: [Visual Studio for Mac](#)

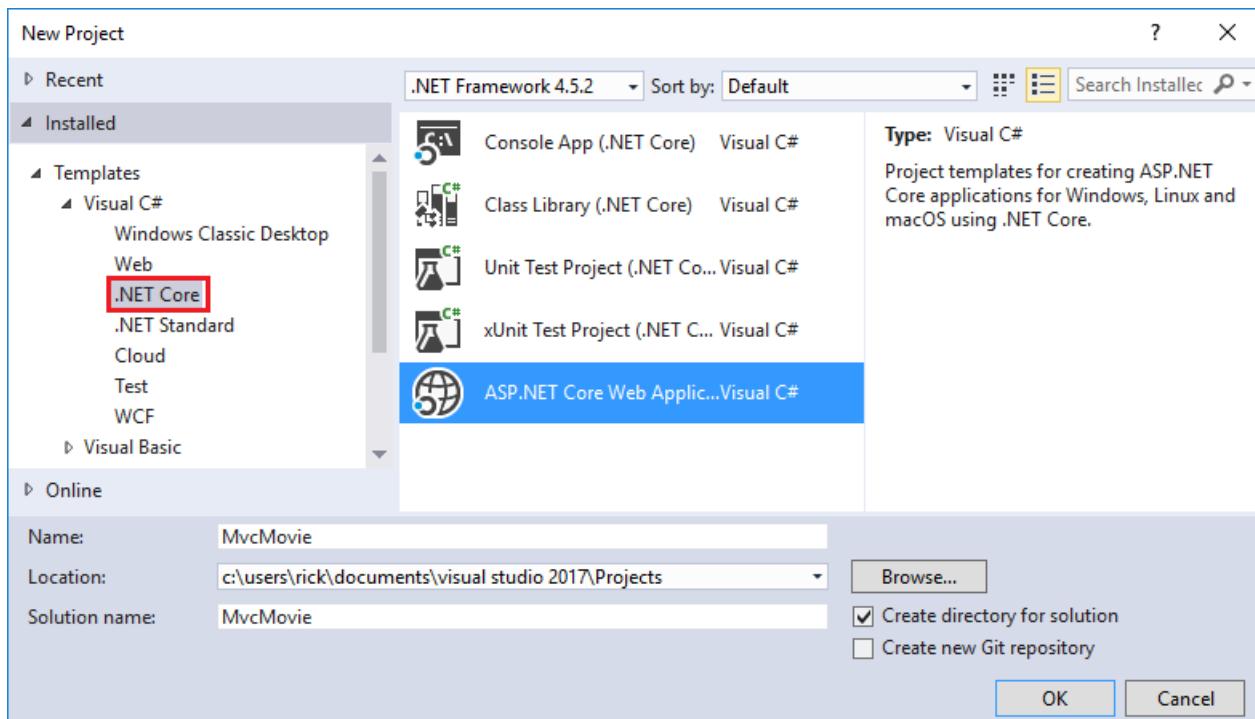

## Create a web app

From Visual Studio, select **File > New > Project**.

Complete the **New Project** dialog:

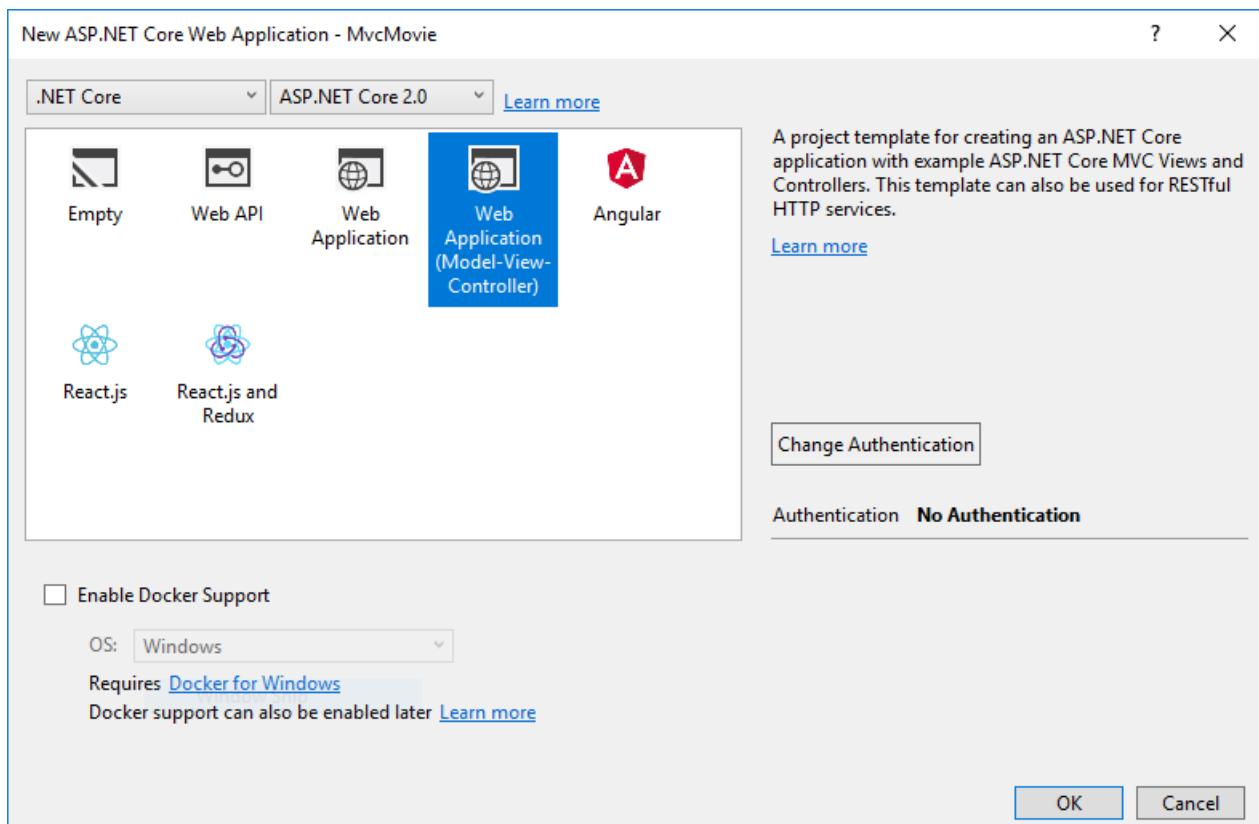

- In the left pane, tap **.NET Core**
- In the center pane, tap **ASP.NET Core Web Application (.NET Core)**
- Name the project "MvcMovie" (It's important to name the project "MvcMovie" so when you copy code, the namespace will match.)
- Tap **OK**

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

# Add a controller to an ASP.NET Core MVC app

7/10/2018 • 5 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

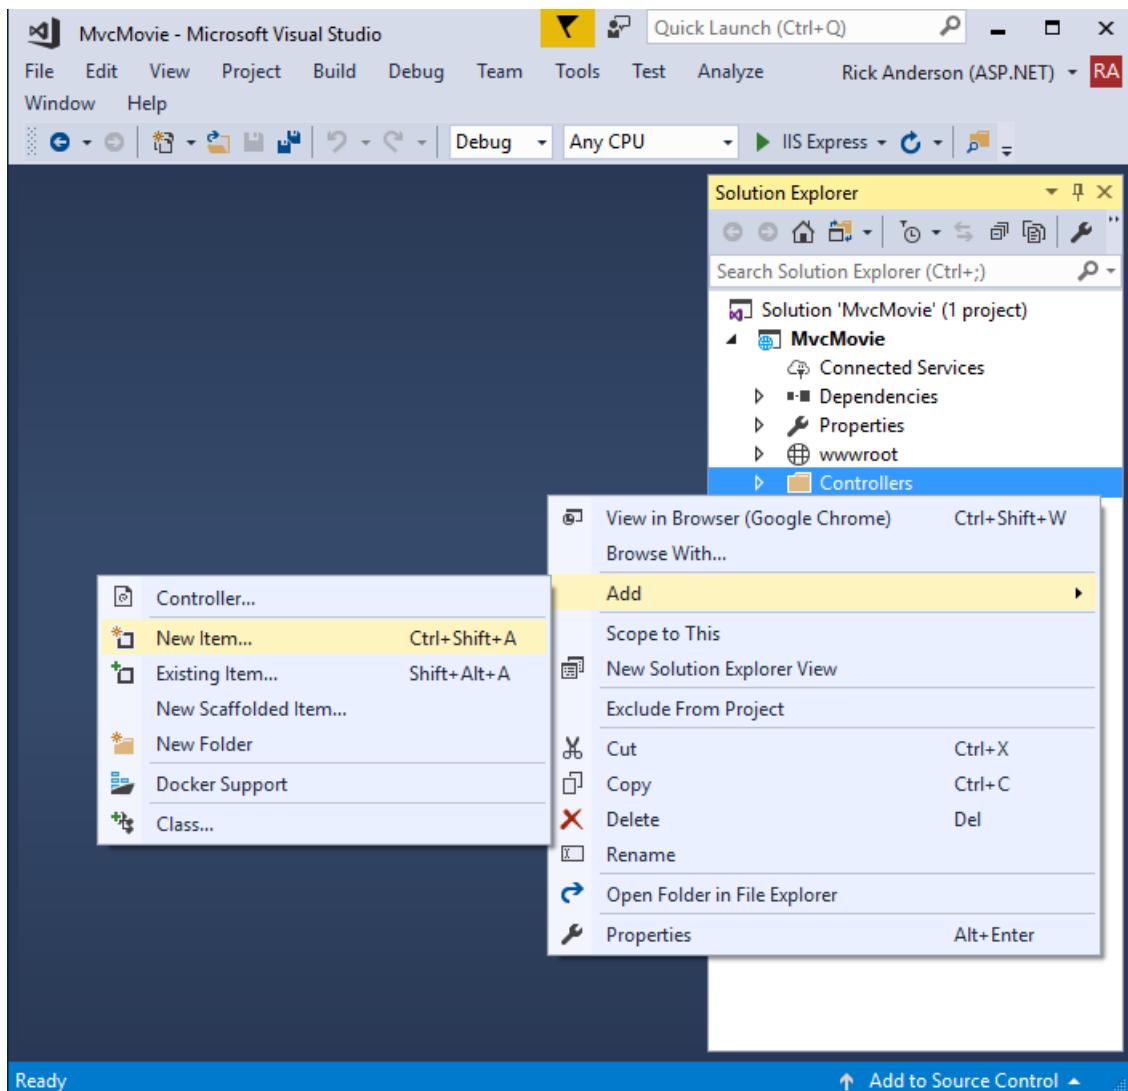

The Model-View-Controller (MVC) architectural pattern separates an app into three main components: **Model**, **View**, and **Controller**. The MVC pattern helps you create apps that are more testable and easier to update than traditional monolithic apps. MVC-based apps contain:

- **Models:** Classes that represent the data of the app. The model classes use validation logic to enforce business rules for that data. Typically, model objects retrieve and store model state in a database. In this tutorial, a `Movie` model retrieves movie data from a database, provides it to the view or updates it. Updated data is written to a database.
- **Views:** Views are the components that display the app's user interface (UI). Generally, this UI displays the model data.
- **Controllers:** Classes that handle browser requests. They retrieve model data and call view templates that return a response. In an MVC app, the view only displays information; the controller handles and responds to user input and interaction. For example, the controller handles route data and query-string values, and passes these values to the model. The model might use these values to query the database. For example, `http://localhost:1234/Home/About` has route data of `Home` (the controller) and `About` (the action method to call on the home controller). `http://localhost:1234/Movies/Edit/5` is a request to edit the movie with ID=5 using the movie controller. We'll talk about route data later in the tutorial.

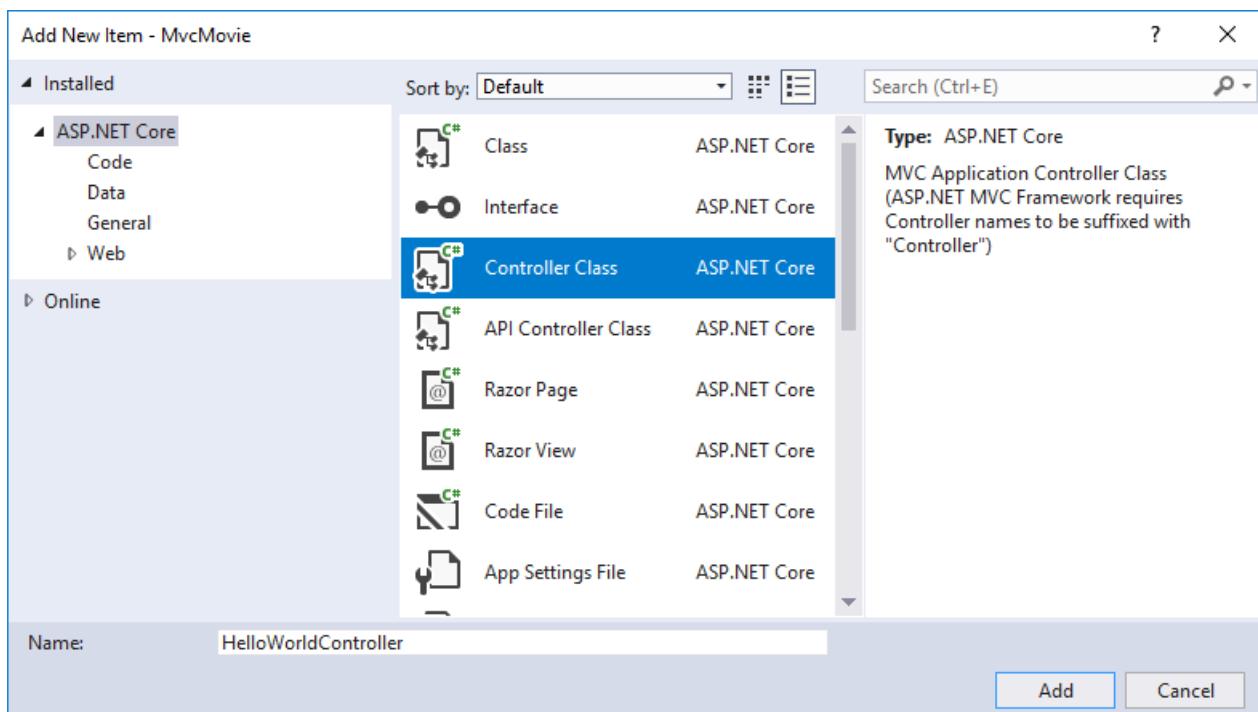

The MVC pattern helps you create apps that separate the different aspects of the app (input logic, business logic, and UI logic), while providing a loose coupling between these elements. The pattern specifies where each kind of logic should be located in the app. The UI logic belongs in the view. Input logic belongs in the controller. Business logic belongs in the model. This separation helps you manage complexity when you build an app, because it enables you to work on one aspect of the implementation at a time without impacting the code of another. For example, you can work on the view code without depending on the business logic code.

We cover these concepts in this tutorial series and show you how to use them to build a movie app. The MVC project contains folders for the *Controllers* and *Views*.

- In **Solution Explorer**, right-click **Controllers** > **Add** > **New Item**

- Select **Controller Class**
- In the **Add New Item** dialog, enter **HelloWorldController**.

Replace the contents of *Controllers/HelloWorldController.cs* with the following:

```

using Microsoft.AspNetCore.Mvc;
using System.Text.Encodings.Web;

namespace MvcMovie.Controllers
{
    public class HelloWorldController : Controller
    {
        //
        // GET: /HelloWorld/

        public string Index()
        {
            return "This is my default action...";
        }

        //
        // GET: /HelloWorld/Welcome/

        public string Welcome()
        {
            return "This is the Welcome action method...";
        }
    }
}

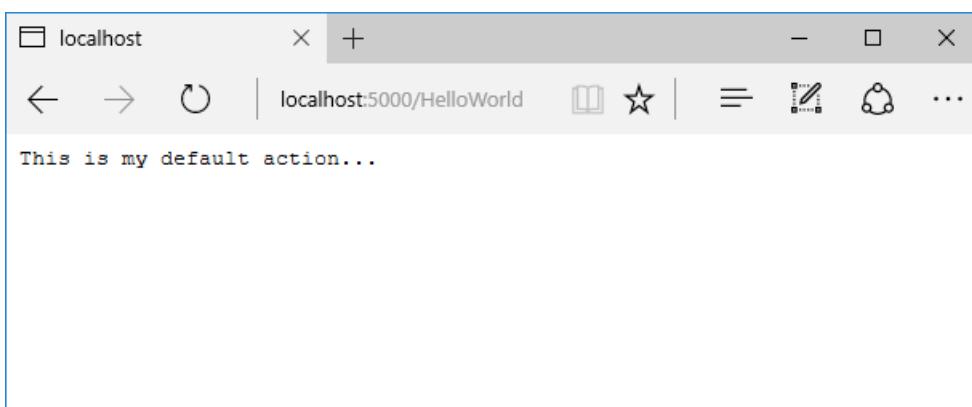

```

Every `public` method in a controller is callable as an HTTP endpoint. In the sample above, both methods return a string. Note the comments preceding each method.

An HTTP endpoint is a targetable URL in the web application, such as `http://localhost:1234/HelloWorld`, and combines the protocol used: `HTTP`, the network location of the web server (including the TCP port): `localhost:1234` and the target URI `HelloWorld`.

The first comment states this is an `HTTP GET` method that's invoked by appending `/HelloWorld/` to the base URL. The second comment specifies an `HTTP GET` method that's invoked by appending `/HelloWorld/Welcome/` to the URL. Later on in the tutorial you'll use the scaffolding engine to generate `HTTP POST` methods.

Run the app in non-debug mode and append "HelloWorld" to the path in the address bar. The `Index` method returns a string.

MVC invokes controller classes (and the action methods within them) depending on the incoming URL. The default [URL routing logic](#) used by MVC uses a format like this to determine what code to invoke:

`/[Controller]/[ActionName]/[Parameters]`

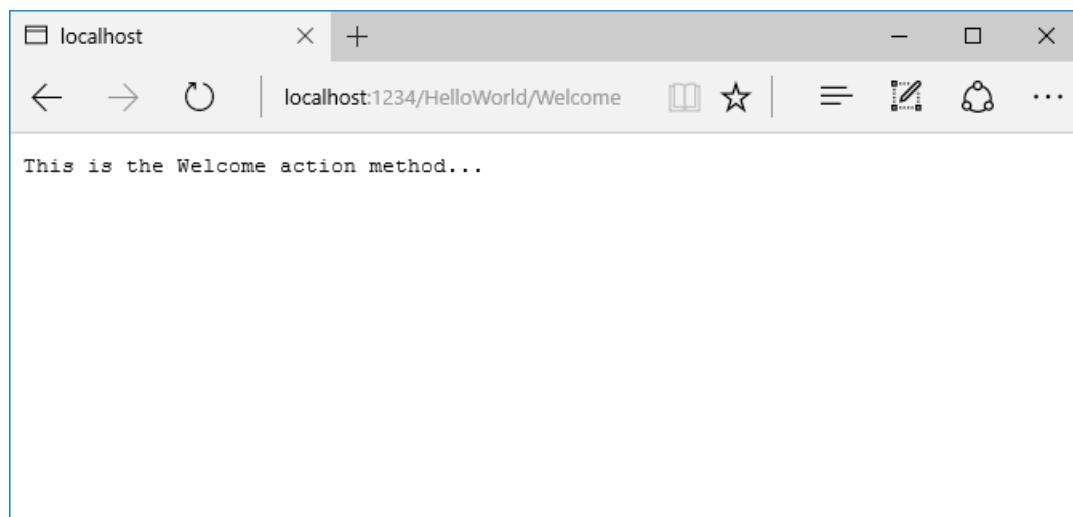

You set the format for routing in the `Configure` method in `Startup.cs` file.

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

When you run the app and don't supply any URL segments, it defaults to the "Home" controller and the "Index" method specified in the template line highlighted above.

The first URL segment determines the controller class to run. So `localhost:xxxx/HelloWorld` maps to the `HelloWorldController` class. The second part of the URL segment determines the action method on the class. So `localhost:xxxx/HelloWorld/Index` would cause the `Index` method of the `HelloWorldController` class to run. Notice that you only had to browse to `localhost:xxxx/HelloWorld` and the `Index` method was called by default. This is because `Index` is the default method that will be called on a controller if a method name isn't explicitly specified. The third part of the URL segment (`id`) is for route data. You'll see route data later on in this tutorial.

Browse to `http://localhost:xxxx/HelloWorld/Welcome`. The `Welcome` method runs and returns the string "This is the Welcome action method...". For this URL, the controller is `HelloWorld` and `Welcome` is the action method. You haven't used the `[Parameters]` part of the URL yet.

Modify the code to pass some parameter information from the URL to the controller. For example, `/HelloWorld/Welcome?name=Rick&numtimes=4`. Change the `Welcome` method to include two parameters as shown in the following code.

```
// GET: /HelloWorld/Welcome/
// Requires using System.Text.Encodings.Web;
public string Welcome(string name, int numTimes = 1)
{
    return HtmlEncoder.Default.Encode($"Hello {name}, NumTimes is: {numTimes}");
}
```

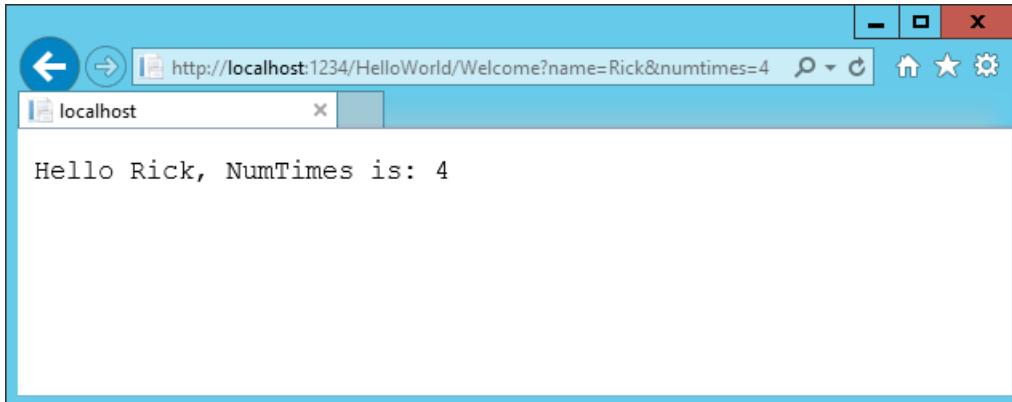

The preceding code:

- Uses the C# optional-parameter feature to indicate that the `numTimes` parameter defaults to 1 if no value is passed for that parameter.
- Uses `HtmlEncoder.Default.Encode` to protect the app from malicious input (namely JavaScript).
- Uses [Interpolated Strings](#).

Run your app and browse to:

```
http://localhost:xxxx/HelloWorld/Welcome?name=Rick&numtimes=4
```

(Replace xxxx with your port number.) You can try different values for `name` and `numtimes` in the URL. The MVC [model binding](#) system automatically maps the named parameters from the query string in the address bar to parameters in your method. See [Model Binding](#) for more information.

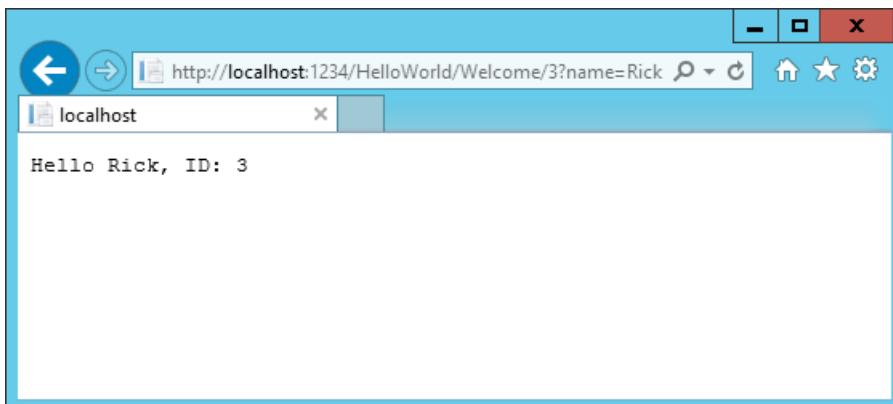

In the image above, the URL segment (`Parameters`) isn't used, the `name` and `numTimes` parameters are passed as [query strings](#). The `?` (question mark) in the above URL is a separator, and the query strings follow. The `&` character separates query strings.

Replace the `Welcome` method with the following code:

```
public string Welcome(string name, int ID = 1)
{
    return HtmlEncoder.Default.Encode($"Hello {name}, ID: {ID}");
}
```

Run the app and enter the following URL: `http://localhost:xxx/HelloWorld/Welcome/3?name=Rick`

This time the third URL segment matched the route parameter `id`. The `Welcome` method contains a parameter `id` that matched the URL template in the `MapRoute` method. The trailing `?` (in `id?`) indicates the `id` parameter is optional.

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

In these examples the controller has been doing the "VC" portion of MVC - that is, the view and controller work. The controller is returning HTML directly. Generally you don't want controllers returning HTML directly, since that becomes very cumbersome to code and maintain. Instead you typically use a separate Razor view template file to

help generate the HTML response. You do that in the next tutorial.

In Visual Studio, in non-debug mode (Ctrl+F5), you don't need to build the app after changing code. Just save the file, refresh your browser and you can see the changes.

[PREVIOUS](#)

[NEXT](#)

# Add a view to an ASP.NET Core MVC app

6/26/2018 • 8 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section you modify the `HelloWorldController` class to use Razor view template files to cleanly encapsulate the process of generating HTML responses to a client.

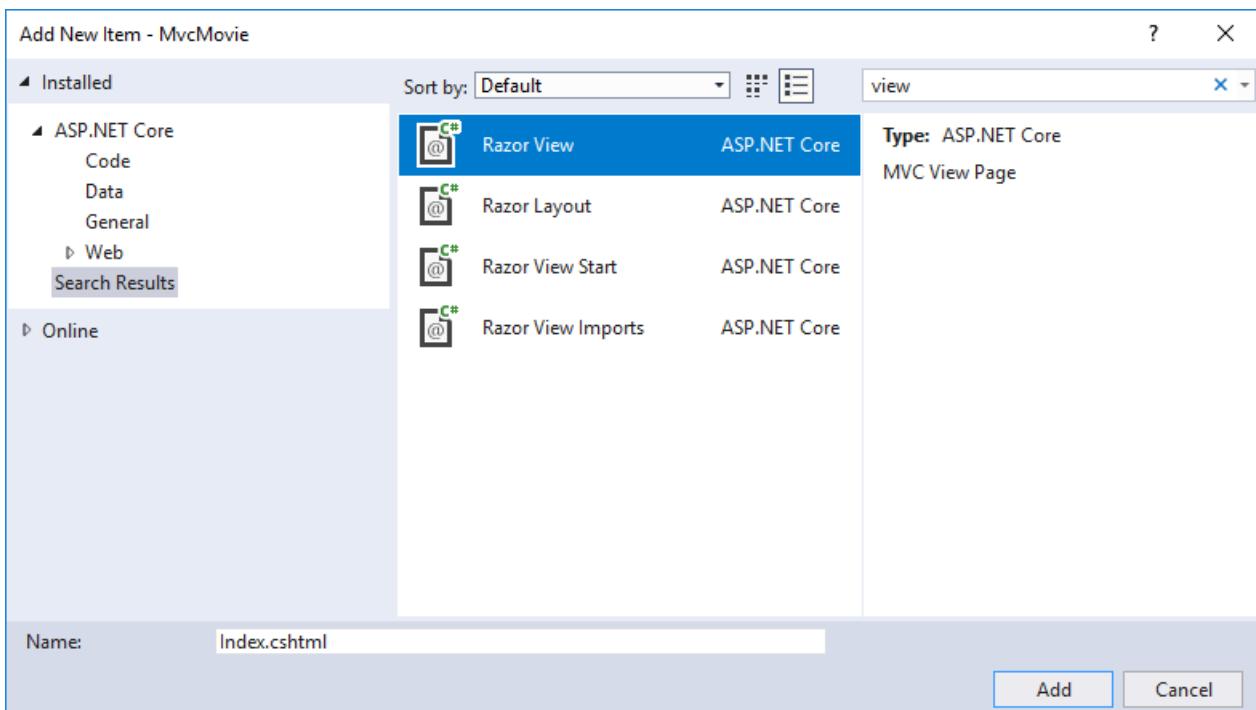

You create a view template file using Razor. Razor-based view templates have a `.cshtml` file extension. They provide an elegant way to create HTML output using C#.

Currently the `Index` method returns a string with a message that's hard-coded in the controller class. In the `HelloWorldController` class, replace the `Index` method with the following code:

```
public IActionResult Index()
{
    return View();
}
```

The preceding code returns a `View` object. It uses a view template to generate an HTML response to the browser. Controller methods (also known as action methods) such as the `Index` method above, generally return an `IActionResult` (or a class derived from `ActionResult`), not a type like `string`.

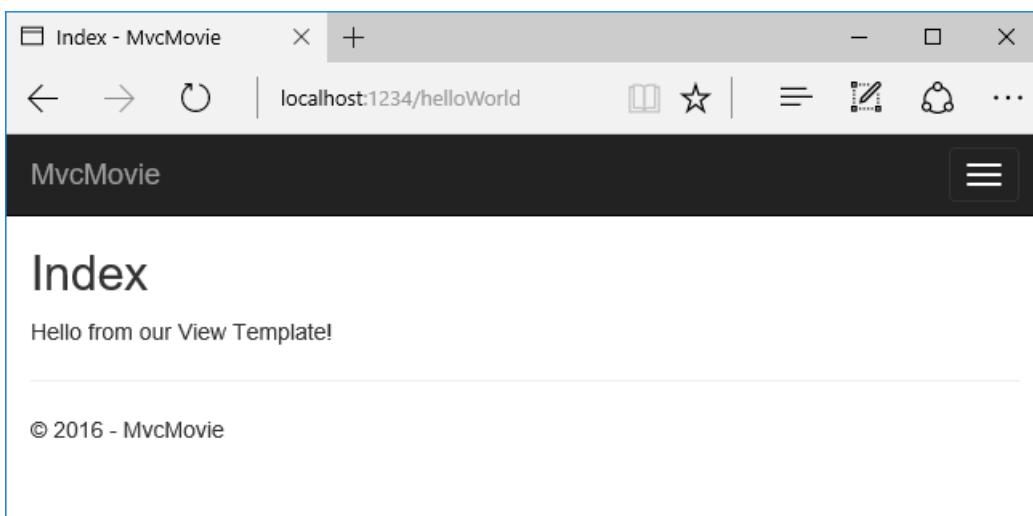

- Right click on the `Views` folder, and then **Add > New Folder** and name the folder `HelloWorld`.
- Right click on the `Views/HelloWorld` folder, and then **Add > New Item**.
- In the **Add New Item - MvcMovie** dialog
  - In the search box in the upper-right, enter `view`
  - Tap **Razor View**
  - In the **Name** box, change the name if necessary to `Index.cshtml`.
  - Tap **Add**

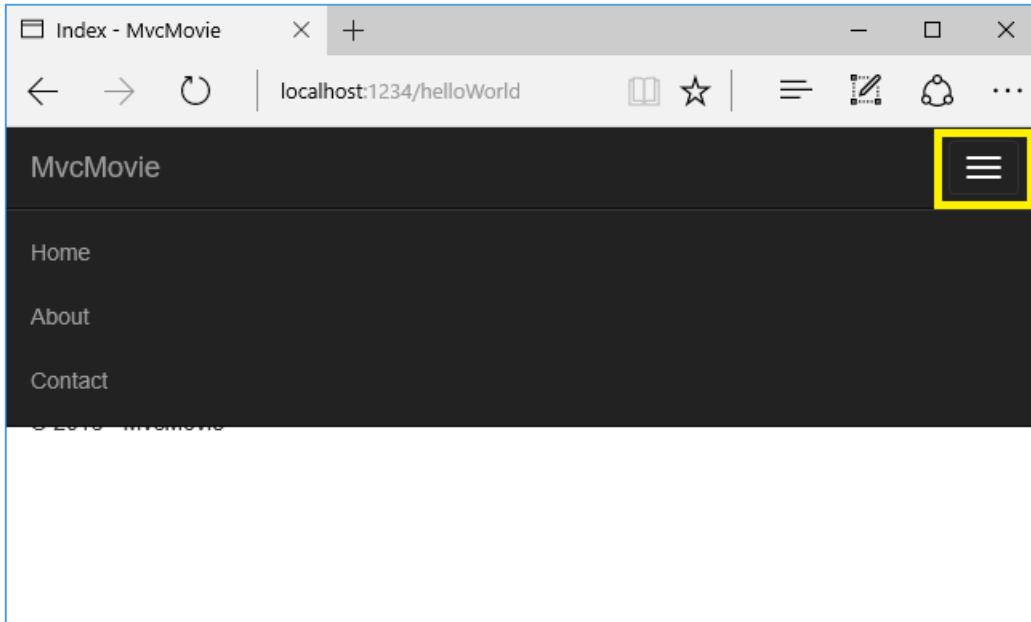

Replace the contents of the `Views/HelloWorld/Index.cshtml` Razor view file with the following:

```
@{  
    ViewData["Title"] = "Index";  
}  
  
<h2>Index</h2>  
  
<p>Hello from our View Template!</p>
```

Navigate to `http://localhost:xxxx>HelloWorld`. The `Index` method in the `HelloWorldController` didn't do much; it ran the statement `return View();`, which specified that the method should use a view template file to render a response to the browser. Because you didn't explicitly specify the name of the view template file, MVC defaulted to using the `Index.cshtml` view file in the `/Views/HelloWorld` folder. The image below shows the string "Hello from our View Template!" hard-coded in the view.

If your browser window is small (for example on a mobile device), you might need to toggle (tap) the [Bootstrap navigation button](#) in the upper right to see the **Home**, **About**, and **Contact** links.

## Changing views and layout pages

Tap the menu links (**MvcMovie**, **Home**, **About**). Each page shows the same menu layout. The menu layout is implemented in the `Views/Shared/_Layout.cshtml` file. Open the `Views/Shared/_Layout.cshtml` file.

**Layout** templates allow you to specify the HTML container layout of your site in one place and then apply it across multiple pages in your site. Find the `@RenderBody()` line. `RenderBody` is a placeholder where all the view-specific pages you create show up, *wrapped* in the layout page. For example, if you select the **About** link, the **Views/Home/About.cshtml** view is rendered inside the `RenderBody` method.

## Change the title and menu link in the layout file

In the title element, change `MvcMovie` to `Movie App`. Change the anchor text in the layout template from `MvcMovie` to `Movie App` and the controller from `Home` to `Movies` as highlighted below:

```
@inject Microsoft.ApplicationInsights.AspNetCore.JavaScriptSnippet JavaScriptSnippet
<!DOCTYPE html>

### WARNING

We haven't implemented the `Movies` controller yet, so if you click on that link, you'll get a 404 (Not found) error.

Save your changes and tap the **About** link. Notice how the title on the browser tab now displays **About - Movie App** instead of **About - Mvc Movie**:

Tap the **Contact** link and notice that the title and anchor text also display **Movie App**. We were able to make the change once in the layout template and have all pages on the site reflect the new link text and new title.

Examine the *Views/\_ViewStart.cshtml* file:

```
@{  
    Layout = "_Layout";  
}
```

The *Views/\_ViewStart.cshtml* file brings in the *Views/Shared/\_Layout.cshtml* file to each view. You can use the `Layout` property to set a different layout view, or set it to `null` so no layout file will be used.

Change the title of the `Index` view.

Open *Views/HelloWorld/Index.cshtml*. There are two places to make a change:

- The text that appears in the title of the browser.
- The secondary header (`<h2>` element).

You'll make them slightly different so you can see which bit of code changes which part of the app.

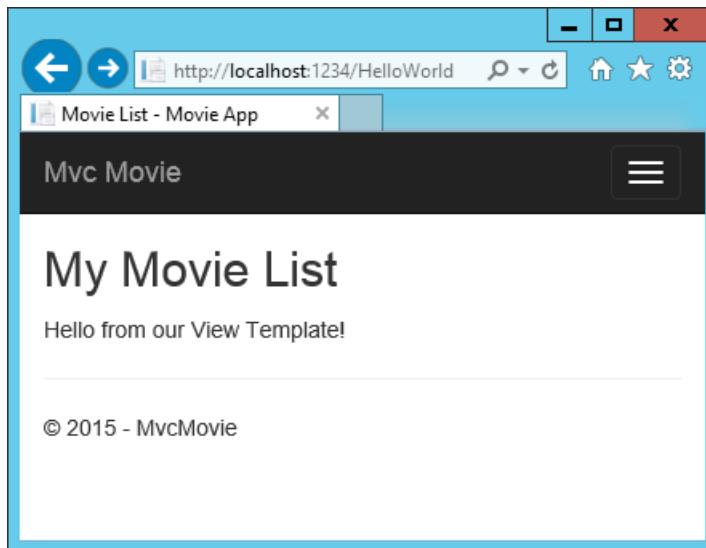

```
@{  
    ViewData["Title"] = "Movie List";  
}  
  
<h2>My Movie List</h2>  
  
<p>Hello from our View Template!</p>
```

`ViewData["Title"] = "Movie List";` in the code above sets the `Title` property of the `ViewData` dictionary to "Movie List". The `Title` property is used in the `<title>` HTML element in the layout page:

```
<title>@ViewData["Title"] - Movie App</title>
```

Save your change and navigate to `http://localhost:xxxx/HelloWorld`. Notice that the browser title, the primary heading, and the secondary headings have changed. (If you don't see changes in the browser, you might be viewing cached content. Press **Ctrl+F5** in your browser to force the response from the server to be loaded.) The browser title is created with `ViewData["Title"]` we set in the *Index.cshtml* view template and the additional "-Movie App" added in the layout file.

Also notice how the content in the *Index.cshtml* view template was merged with the *Views/Shared/\_Layout.cshtml* view template and a single HTML response was sent to the browser. Layout templates make it really easy to make changes that apply across all of the pages in your application. To learn more see [Layout](#).

Our little bit of "data" (in this case the "Hello from our View Template!" message) is hard-coded, though. The MVC application has a "V" (view) and you've got a "C" (controller), but no "M" (model) yet.

## Passing Data from the Controller to the View

Controller actions are invoked in response to an incoming URL request. A controller class is where you write the code that handles the incoming browser requests. The controller retrieves data from a data source and decides what type of response to send back to the browser. View templates can be used from a controller to generate and format an HTML response to the browser.

Controllers are responsible for providing the data required in order for a view template to render a response. A best practice: View templates should **not** perform business logic or interact with a database directly. Rather, a view template should work only with the data that's provided to it by the controller. Maintaining this "separation of concerns" helps keep your code clean, testable, and maintainable.

Currently, the `Welcome` method in the `HelloWorldController` class takes a `name` and a `ID` parameter and then outputs the values directly to the browser. Rather than have the controller render this response as a string, change the controller to use a view template instead. The view template generates a dynamic response, which means that appropriate bits of data must be passed from the controller to the view in order to generate the response. Do this by having the controller put the dynamic data (parameters) that the view template needs in a `ViewData` dictionary that the view template can then access.

Return to the `HelloWorldController.cs` file and change the `Welcome` method to add a `Message` and `NumTimes` value to the `ViewData` dictionary. The `ViewData` dictionary is a dynamic object, which means you can put whatever you want in to it; the `ViewData` object has no defined properties until you put something inside it. The [MVC model binding system](#) automatically maps the named parameters (`name` and `numTimes`) from the query string in the address bar to parameters in your method. The complete `HelloWorldController.cs` file looks like this:

```

using Microsoft.AspNetCore.Mvc;
using System.Text.Encodings.Web;

namespace MvcMovie.Controllers
{
    public class HelloWorldController : Controller
    {
        public IActionResult Index()
        {
            return View();
        }

        public IActionResult Welcome(string name, int numTimes = 1)
        {
            ViewData["Message"] = "Hello " + name;
            ViewData["NumTimes"] = numTimes;

            return View();
        }
    }
}

```

The `viewData` dictionary object contains data that will be passed to the view.

Create a Welcome view template named `Views/HelloWorld/Welcome.cshtml`.

You'll create a loop in the `Welcome.cshtml` view template that displays "Hello" `NumTimes`. Replace the contents of `Views/HelloWorld/Welcome.cshtml` with the following:

```

@{
    ViewData["Title"] = "Welcome";
}

<h2>Welcome</h2>

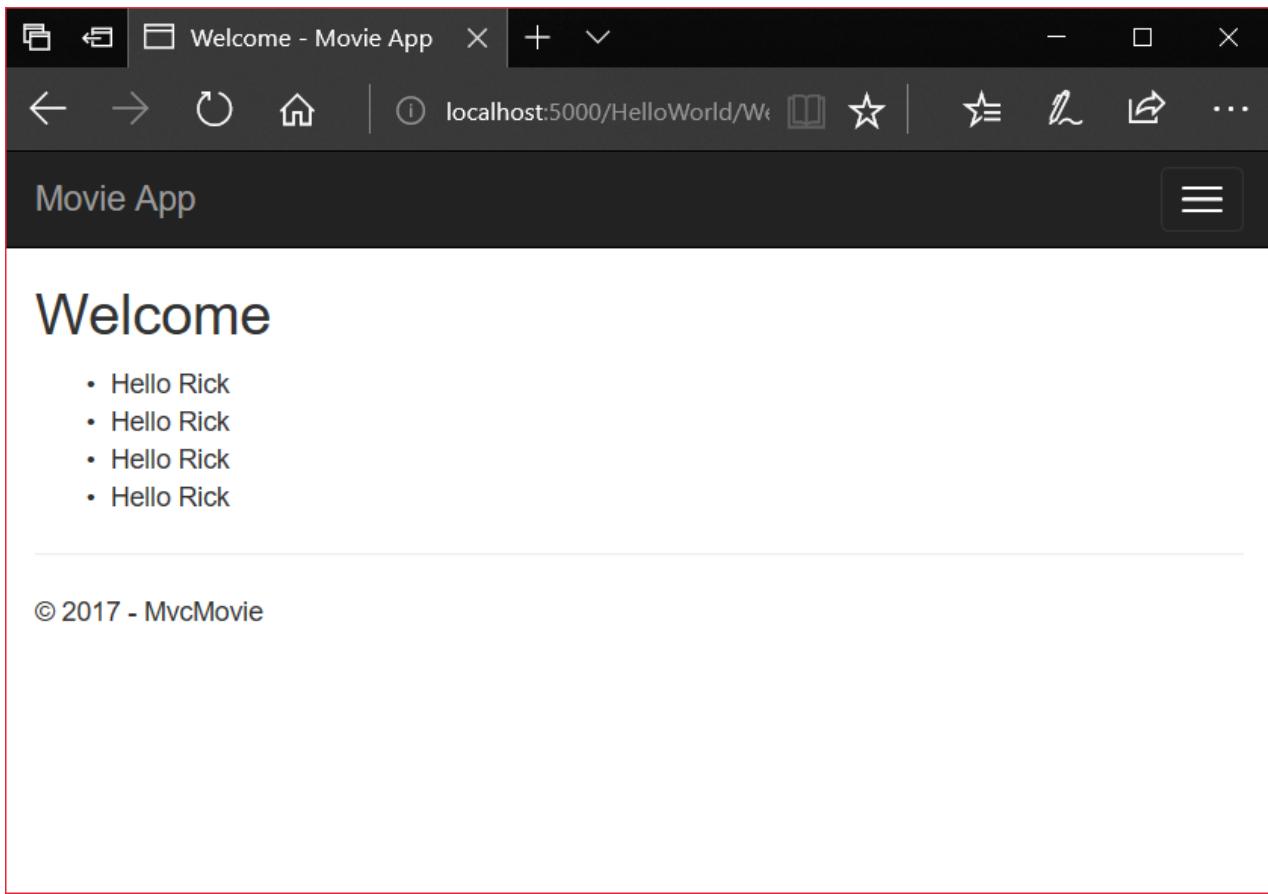

<ul>
    @for (int i = 0; i < (int)ViewData["NumTimes"]; i++)
    {
        <li>@ViewData["Message"]</li>
    }
</ul>

```

Save your changes and browse to the following URL:

`http://localhost:xxxx/HelloWorld/Welcome?name=Rick&numtimes=4`

Data is taken from the URL and passed to the controller using the [MVC model binder](#). The controller packages the data into a `viewData` dictionary and passes that object to the view. The view then renders the data as HTML to the browser.

In the sample above, we used the `ViewData` dictionary to pass data from the controller to a view. Later in the tutorial, we will use a view model to pass data from a controller to a view. The view model approach to passing data is generally much preferred over the `ViewData` dictionary approach. See [ViewModel vs ViewData vs ViewBag vs TempData vs Session in MVC](#) for more information.

Well, that was a kind of an "M" for model, but not the database kind. Let's take what we've learned and create a database of movies.

[PREVIOUS](#) [NEXT](#)

# Add a model to an ASP.NET Core MVC app

6/26/2018 • 10 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Tom Dykstra](#)

In this section, you'll add some classes for managing movies in a database. These classes will be the "**Model**" part of the **MVC** app.

You use these classes with [Entity Framework Core](#) (EF Core) to work with a database. EF Core is an object-relational mapping (ORM) framework that simplifies the data access code that you have to write. [EF Core supports many database engines](#).

The model classes you'll create are known as POCO classes (from "plain-old CLR objects") because they don't have any dependency on EF Core. They just define the properties of the data that will be stored in the database.

In this tutorial you'll write the model classes first, and EF Core will create the database. An alternate approach not covered here is to generate model classes from an already-existing database. For information about that approach, see [ASP.NET Core - Existing Database](#).

## Add a data model class

Right-click the *Models* folder > **Add** > **Class**. Name the class **Movie** and add the following properties:

```
using System;

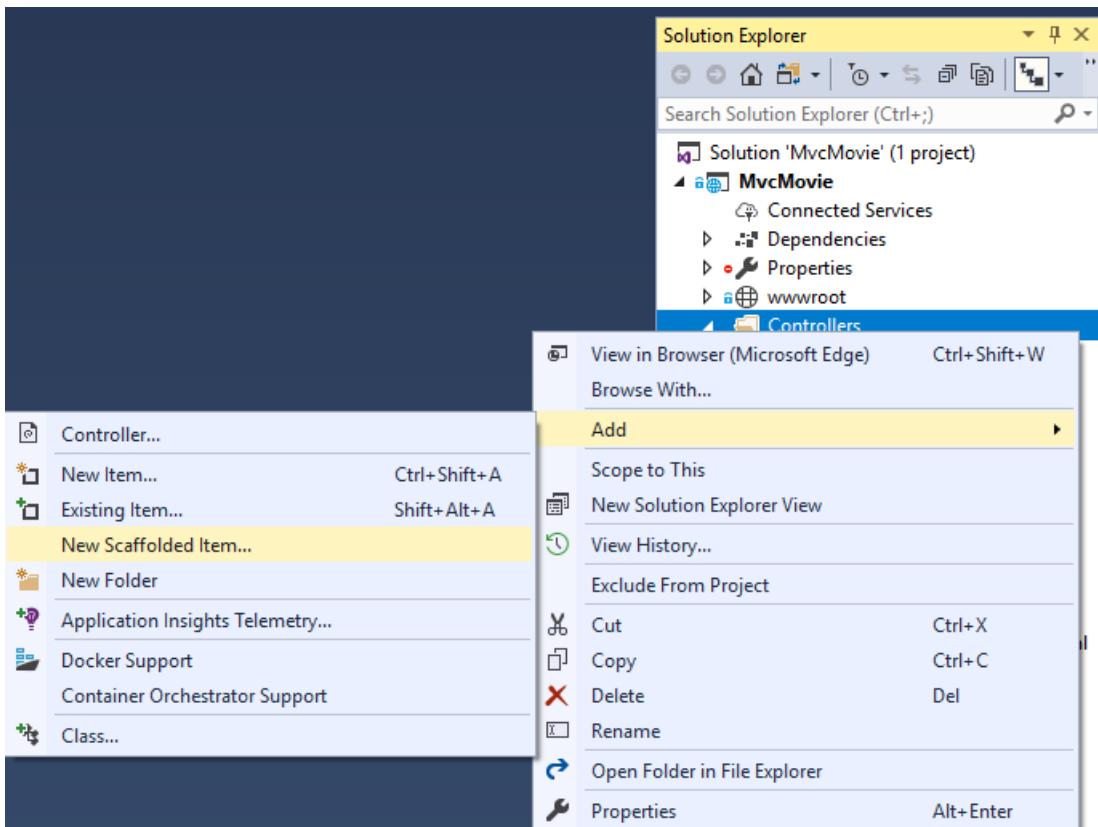

namespace MvcMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

The `ID` field is required by the database for the primary key.

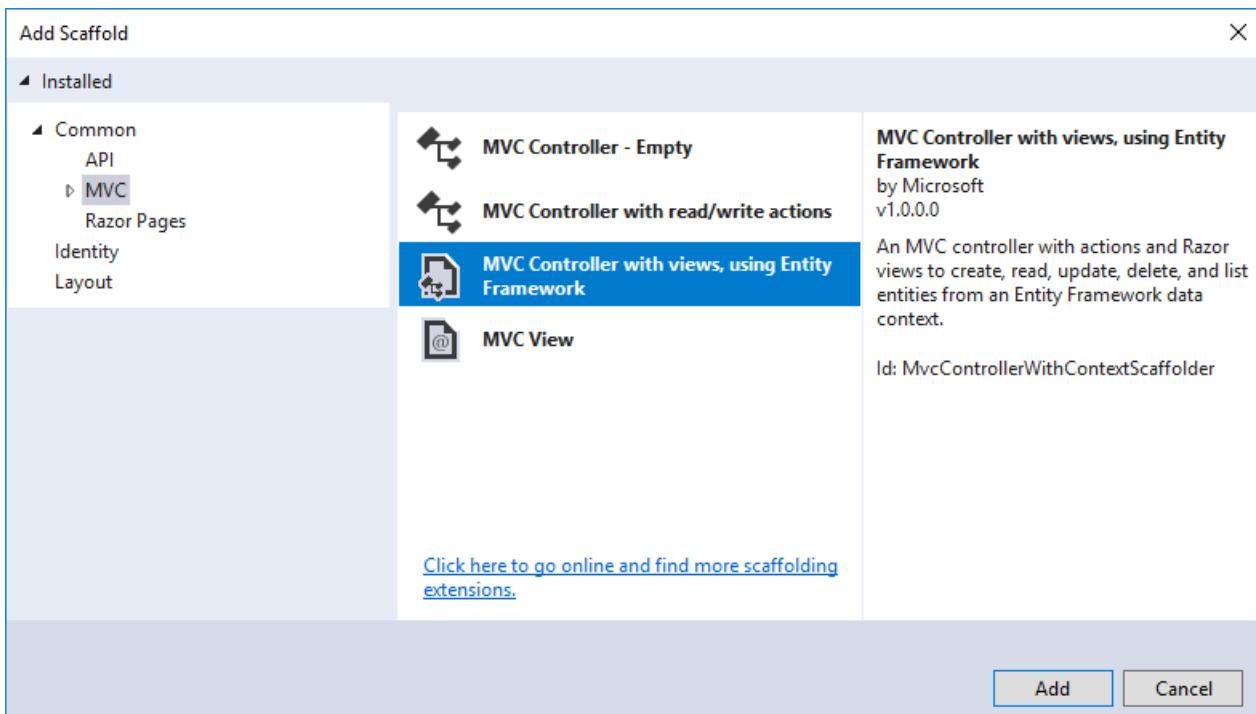

Build the project to verify you don't have any errors. You now have a **Model** in your **MVC** app.

## Scaffolding a controller

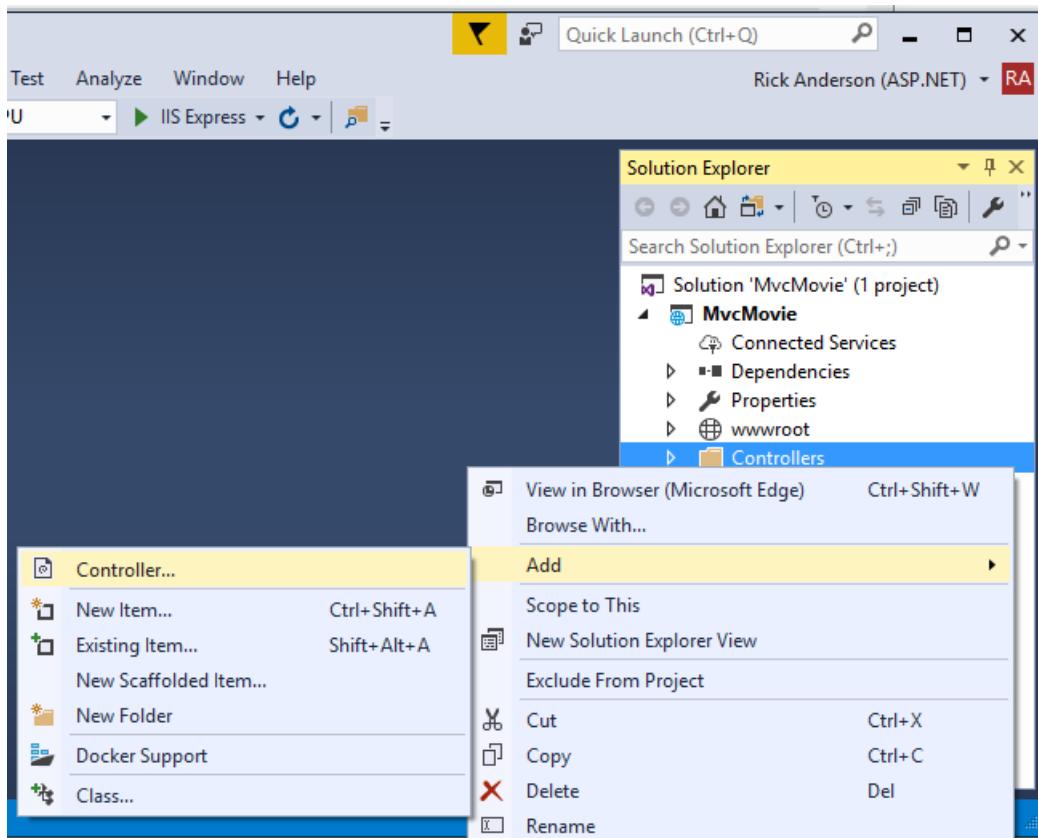

In **Solution Explorer**, right-click the *Controllers* folder > **Add** > **New Scaffolded Item**.

In the **Add Scaffold** dialog, tap **MVC Controller with views, using Entity Framework > Add**.

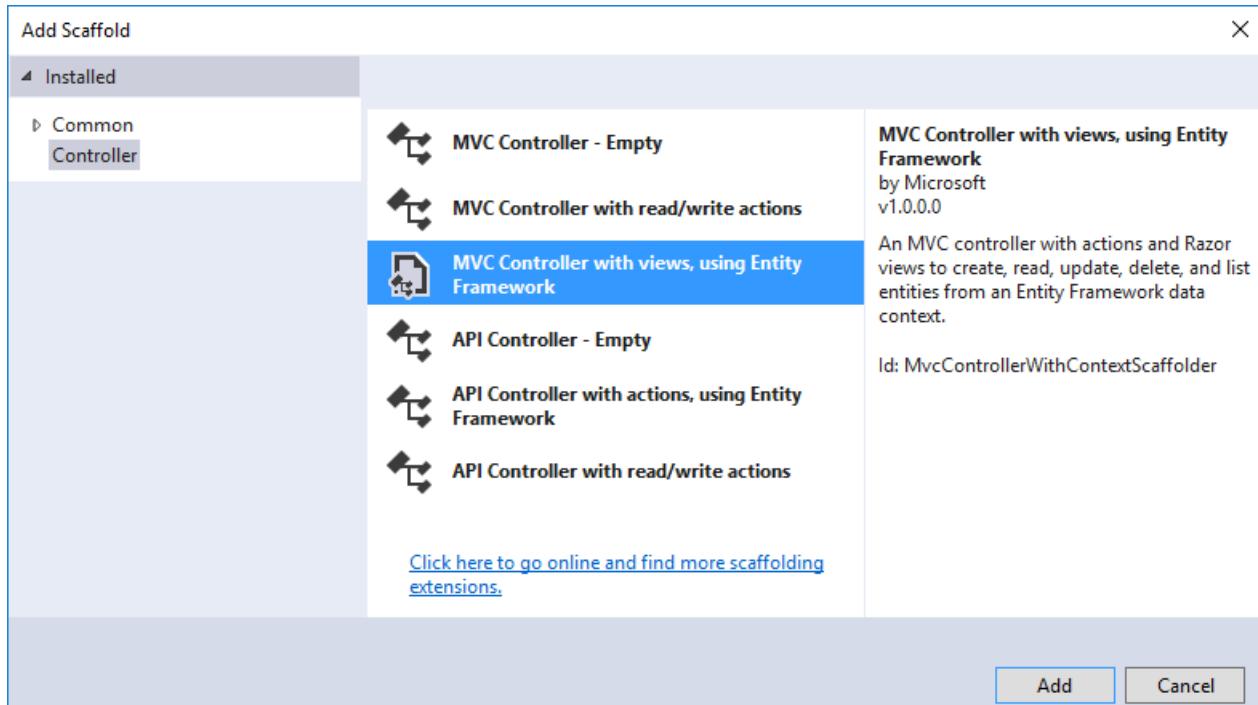

In **Solution Explorer**, right-click the *Controllers* folder > **Add > Controller**.

If the **Add MVC Dependencies** dialog appears:

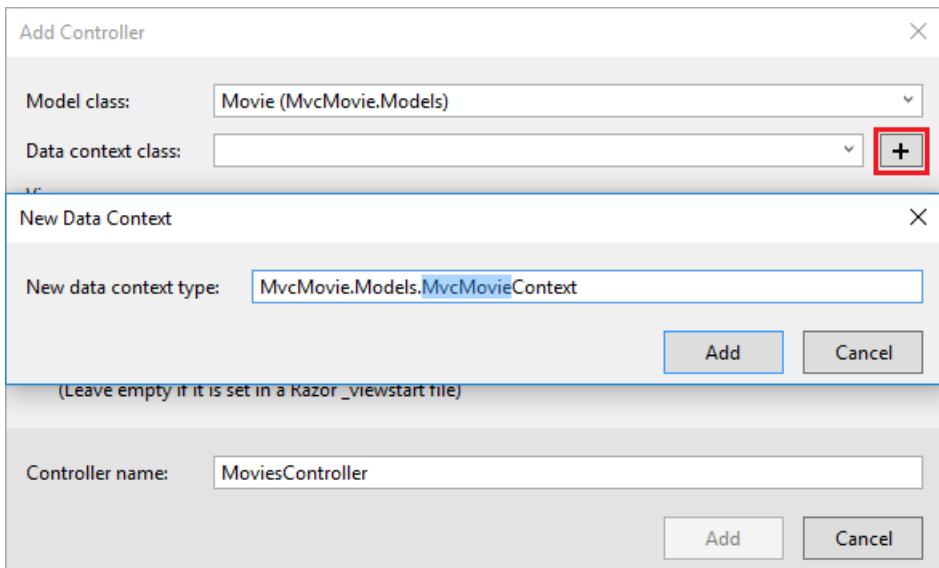

- [Update Visual Studio to the latest version](#). Visual Studio versions prior to 15.5 show this dialog.
- If you can't update, select **ADD**, and then follow the add controller steps again.

In the **Add Scaffold** dialog, tap **MVC Controller with views, using Entity Framework > Add**.

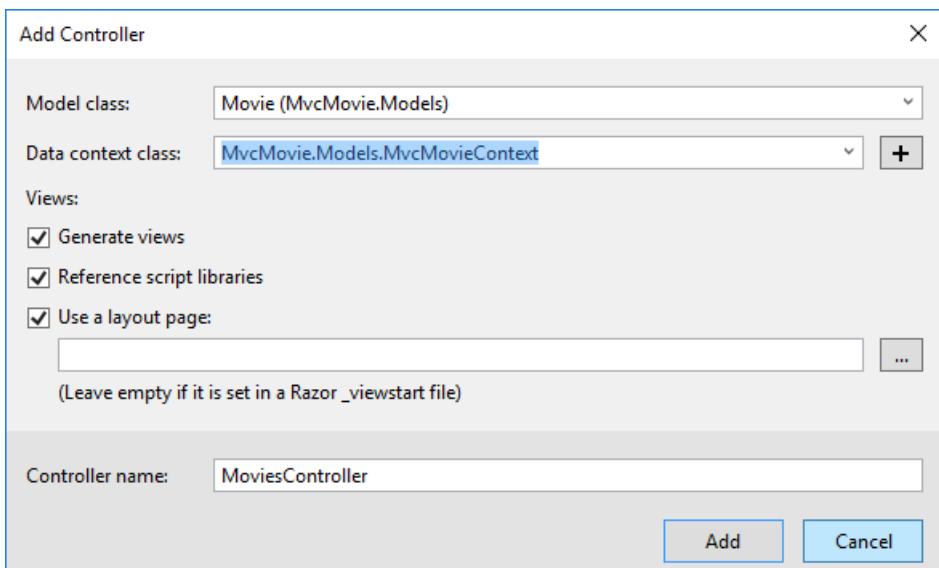

Complete the **Add Controller** dialog:

- **Model class:** Movie (`MvcMovie.Models.Movie`)
- **Data context class:** Select the + icon and add the default `MvcMovie.Models.MvcMovieContext`

- **Views:** Keep the default of each option checked
- **Controller name:** Keep the default *MoviesController*
- Tap **Add**

Visual Studio creates:

- An Entity Framework Core **database context class** (*Data/MvcMovieContext.cs*)
- A movies controller (*Controllers/MoviesController.cs*)
- Razor view files for Create, Delete, Details, Edit, and Index pages (*Views/Movies/\*.cshtml*)

The automatic creation of the database context and **CRUD** (create, read, update, and delete) action methods and views is known as *scaffolding*. You'll soon have a fully functional web application that lets you manage a movie database.

If you run the app and click on the **Mvc Movie** link, you get an error similar to the following:

```
An unhandled exception occurred while processing the request.

SqlException: Cannot open database "MvcMovieContext-<GUID removed>" requested by the login. The login failed.
Login failed for user 'Rick'.

System.Data.SqlClient.SqlInternalConnectionTds..ctor(DbConnectionPoolIdentity identity, SqlConnectionString
```

You need to create the database, and you'll use the EF Core **Migrations** feature to do that. Migrations lets you

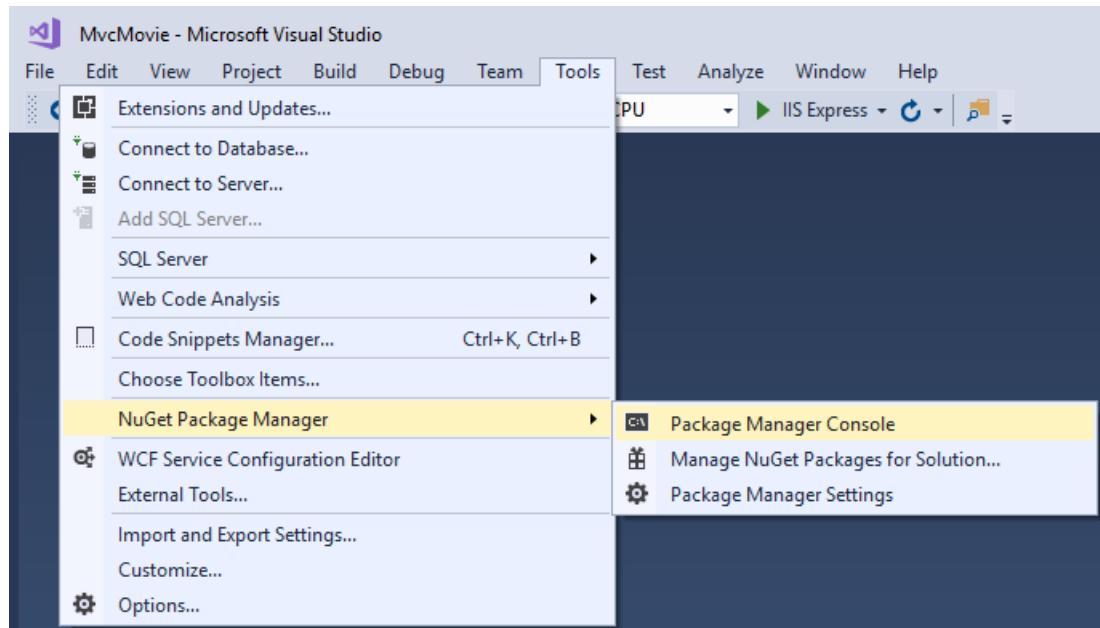

create a database that matches your data model and update the database schema when your data model changes.

## Add EF tooling and perform initial migration

In this section you'll use the Package Manager Console (PMC) to:

- Add the Entity Framework Core Tools package. This package is required to add migrations and update the database.
- Add an initial migration.
- Update the database with the initial migration.

From the **Tools** menu, select **NuGet Package Manager > Package Manager Console**.

In the PMC, enter the following commands:

```
Add-Migration Initial  
Update-Database
```

Ignore the following error message, we fix it in the next tutorial:

```
Microsoft.EntityFrameworkCore.Model.Validation[30000]  
No type was specified for the decimal column 'Price' on entity type 'Movie'. This will cause values to be silently truncated if they do not fit in the default precision and scale. Explicitly specify the SQL server column type that can accommodate all the values using 'ForHasColumnType()'.
```

```
Install-Package Microsoft.EntityFrameworkCore.Tools  
Add-Migration Initial  
Update-Database
```

**Note:** If you receive an error with the `Install-Package` command, open NuGet Package Manager and search for the `Microsoft.EntityFrameworkCore.Tools` package. This allows you to install the package or check if it's already installed. Alternatively, see the [CLI approach](#) if you have problems with the PMC.

The `Add-Migration` command creates code to create the initial database schema. The schema is based on the model specified in the `DbContext` (In the `Data/MvcMovieContext.cs` file). The `Initial` argument is used to name the migrations. You can use any name, but by convention you choose a name that describes the migration. See [Introduction to migrations](#) for more information.

The `Update-Database` command runs the `Up` method in the *Migrations/<time-stamp>\_Initial.cs* file, which creates the database.

You can perform the preceding steps using the command-line interface (CLI) rather than the PMC:

- Add [EF Core tooling](#) to the *.csproj* file.
- Run the following commands from the console (in the project directory):

```
dotnet ef migrations add Initial  
dotnet ef database update
```

If you run the app and get the error:

```
SqlException: Cannot open database "Movie" requested by the login.  
The login failed.  
Login failed for user 'user name'.
```

You probably have not run `dotnet ef database update`.

## Test the app

- Run the app and tap the **Mvc Movie** link.
- Tap the **Create New** link and create a movie.

The screenshot shows a browser window titled "Create - Movie App" with the URL "localhost:1234/Movies/". The page is titled "MvcMovie" and has a header "Create". The form is for creating a "Movie" with fields: "Title" (Conan), "Release Date" (3/3/2017), "Genre" (Comedy), and "Price" (1.99). A "Create" button is at the bottom.

- You may not be able to enter decimal points or commas in the `Price` field. To support [jQuery validation](#) for non-English locales that use a comma (",") for a decimal point, and non US-English date formats, you must take steps to globalize your app. See <https://github.com/aspnet/Docs/issues/4076> and [Additional resources](#) for more information. For now, just enter whole numbers like 10.
- In some locales you need to specify the date format. See the highlighted code below.

```
using System;
using System.ComponentModel.DataAnnotations;

namespace MvcMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

We'll talk about `DataAnnotations` later in the tutorial.

Tapping **Create** causes the form to be posted to the server, where the movie information is saved in a database. The app redirects to the /Movies URL, where the newly created movie information is displayed.

The screenshot shows a browser window titled "Index - Movie App". The address bar says "localhost:1234/Movies". The main content area is titled "MvcMovie" and has a heading "Index". Below the heading is a link "Create New". A table lists one movie entry:

Title	Release Date	Genre	Price
Conan	3/3/2017	Comedy	\$1.99

Below the table is a copyright notice: © 2017 - MvcMovie.

Create a couple more movie entries. Try the **Edit**, **Details**, and **Delete** links, which are all functional.

```
public void ConfigureServices(IServiceCollection services)
{
    services.Configure<CookiePolicyOptions>(options =>
    {
        // This lambda determines whether user consent for non-essential cookies is needed for a given
        request.
        options.CheckConsentNeeded = context => true;
        options.MinimumSameSitePolicy = SameSiteMode.None;
    });

    services.AddMvc().SetCompatibilityVersion(CompatibilityVersion.Version_2_1);

    services.AddDbContext<MvcMovieContext>(options =>
        options.UseSqlServer(Configuration.GetConnectionString("MvcMovieContext")));
}
```

```
public void ConfigureServices(IServiceCollection services)
{
    // Add framework services.
    services.AddMvc();

    services.AddDbContext<MvcMovieContext>(options =>
        options.UseSqlServer(Configuration.GetConnectionString("MvcMovieContext")));
}
```

The highlighted code above shows the movie database context being added to the [Dependency Injection](#) container (In the *Startup.cs* file). `services.AddDbContext<MvcMovieContext>(options =>` specifies the database to use and the connection string. `=>` is a [lambda operator](#).

Open the *Controllers/MoviesController.cs* file and examine the constructor:

```
public class MoviesController : Controller
{
    private readonly MvcMovieContext _context;

    public MoviesController(MvcMovieContext context)
    {
        _context = context;
    }
}
```

The constructor uses [Dependency Injection](#) to inject the database context (`MvcMovieContext`) into the controller. The database context is used in each of the [CRUD](#) methods in the controller.

## Strongly typed models and the `@model` keyword

Earlier in this tutorial, you saw how a controller can pass data or objects to a view using the `ViewData` dictionary. The `ViewData` dictionary is a dynamic object that provides a convenient late-bound way to pass information to a view.

MVC also provides the ability to pass strongly typed model objects to a view. This strongly typed approach enables better compile-time checking of your code. The scaffolding mechanism used this approach (that is, passing a strongly typed model) with the `MoviesController` class and views when it created the methods and views.

Examine the generated `Details` method in the `Controllers/MoviesController.cs` file:

```
// GET: Movies/Details/5
public async Task<IActionResult> Details(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .FirstOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}
```

```
// GET: Movies/Details/5
public async Task<IActionResult> Details(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .SingleOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}
```

The `id` parameter is generally passed as route data. For example `http://localhost:5000/movies/details/1` sets:

- The controller to the `movies` controller (the first URL segment).
- The action to `details` (the second URL segment).
- The id to 1 (the last URL segment).

You can also pass in the `id` with a query string as follows:

```
http://localhost:1234/movies/details?id=1
```

The `id` parameter is defined as a [nullable type](#) (`int?`) in case an ID value isn't provided.

A [lambda expression](#) is passed in to `FirstOrDefaultAsync` to select movie entities that match the route data or query string value.

```
var movie = await _context.Movie
    .FirstOrDefaultAsync(m => m.ID == id);
```

A [lambda expression](#) is passed in to `SingleOrDefaultAsync` to select movie entities that match the route data or query string value.

```
var movie = await _context.Movie
    .SingleOrDefaultAsync(m => m.ID == id);
```

If a movie is found, an instance of the `Movie` model is passed to the `Details` view:

```
return View(movie);
```

Examine the contents of the `Views/Movies/Details.cshtml` file:

```

@model MvcMovie.Models.Movie

 @{
    ViewData["Title"] = "Details";
}

<h2>Details</h2>

<div>
    <h4>Movie</h4>
    <hr />
    <dl class="dl-horizontal">
        <dt>
            @Html.DisplayNameFor(model => model.Title)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Title)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.ReleaseDate)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.ReleaseDate)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Genre)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Genre)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Price)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Price)
        </dd>
    </dl>
</div>
<div>
    <a asp-action="Edit" asp-route-id="@Model.ID">Edit</a> |
    <a asp-action="Index">Back to List</a>
</div>

```

By including a `@model` statement at the top of the view file, you can specify the type of object that the view expects. When you created the movie controller, Visual Studio automatically included the following `@model` statement at the top of the *Details.cshtml* file:

```

@model MvcMovie.Models.Movie

```

This `@model` directive allows you to access the movie that the controller passed to the view by using a `Model` object that's strongly typed. For example, in the *Details.cshtml* view, the code passes each movie field to the `DisplayNameFor` and `DisplayFor` HTML Helpers with the strongly typed `Model` object. The `Create` and `Edit` methods and views also pass a `Movie` model object.

Examine the *Index.cshtml* view and the `Index` method in the *Movies* controller. Notice how the code creates a `List` object when it calls the `View` method. The code passes this `Movies` list from the `Index` action method to the view:

```
// GET: Movies
public async Task<IActionResult> Index()
{
    return View(await _context.Movie.ToListAsync());
}
```

When you created the movies controller, scaffolding automatically included the following `@model` statement at the top of the *Index.cshtml* file:

```
@model IEnumerable<MvcMovie.Models.Movie>
```

The `@model` directive allows you to access the list of movies that the controller passed to the view by using a `Model` object that's strongly typed. For example, in the *Index.cshtml* view, the code loops through the movies with a `foreach` statement over the strongly typed `Model` object:

```

@model IEnumerable<MvcMovie.Models.Movie>

 @{
    ViewData["Title"] = "Index";
}

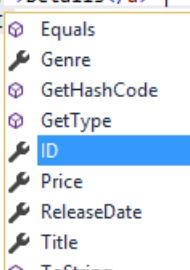

<h2>Index</h2>

<p>
    <a asp-action="Create">Create New</a>
</p>
<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.Title)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.ReleaseDate)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Genre)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Price)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
@foreach (var item in Model) {
        <tr>
            <td>
                @Html.DisplayFor(modelItem => item.Title)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.ReleaseDate)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.Genre)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.Price)
            </td>
            <td>
                <a asp-action="Edit" asp-route-id="@item.ID">Edit</a> |
                <a asp-action="Details" asp-route-id="@item.ID">Details</a> |
                <a asp-action="Delete" asp-route-id="@item.ID">Delete</a>
            </td>
        </tr>
}
    </tbody>
</table>

```

Because the `Model` object is strongly typed (as an `IEnumerable<Movie>` object), each item in the loop is typed as `Movie`. Among other benefits, this means that you get compile-time checking of the code:

```
@foreach (var item in Model) {
    <tr>
        <td>
            @Html.DisplayFor(modelItem => item.Genre)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.Price)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.ReleaseDate)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.Title)
        </td>
        <td>
            <a asp-action="Edit" asp-route-id="@item.ID">Edit</a> | 
            <a asp-action="Details" asp-route-id="@item.ID">Details</a> | 
            <a asp-action="Delete" asp-route-id="@item.ID">Delete</a>
        </td>
    </tr>
}
</table>
```

# Work with SQL Server LocalDB in ASP.NET Core

7/6/2018 • 3 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

The `MvcMovieContext` object handles the task of connecting to the database and mapping `Movie` objects to database records. The database context is registered with the [Dependency Injection](#) container in the `ConfigureServices` method in the `Startup.cs` file:

```
public void ConfigureServices(IServiceCollection services)
{
    services.Configure<CookiePolicyOptions>(options =>
    {
        // This lambda determines whether user consent for non-essential cookies is needed for a given
        request.
        options.CheckConsentNeeded = context => true;
        options.MinimumSameSitePolicy = SameSiteMode.None;
    });

    services.AddMvc().SetCompatibilityVersion(CompatibilityVersion.Version_2_1);

    services.AddDbContext<MvcMovieContext>(options =>
        options.UseSqlServer(Configuration.GetConnectionString("MvcMovieContext")));
}
```

```
public void ConfigureServices(IServiceCollection services)
{
    // Add framework services.
    services.AddMvc();

    services.AddDbContext<MvcMovieContext>(options =>
        options.UseSqlServer(Configuration.GetConnectionString("MvcMovieContext")));
}
```

The ASP.NET Core [Configuration](#) system reads the `ConnectionString`. For local development, it gets the connection string from the `appsettings.json` file:

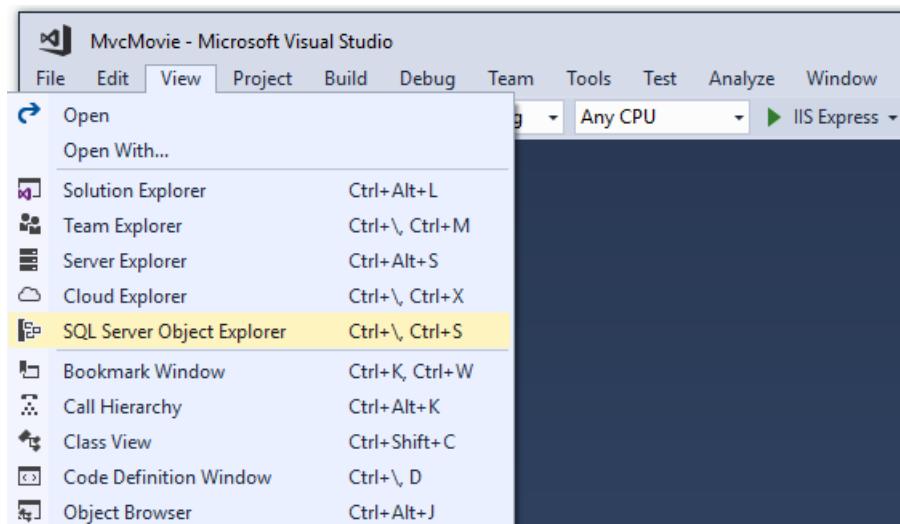

```
"ConnectionStrings": {
    "MvcMovieContext": "Server=(localdb)\\mssqllocaldb;Database=MvcMovieContext-
    2;Trusted_Connection=True;MultipleActiveResultSets=true"
}
```

When you deploy the app to a test or production server, you can use an environment variable or another approach to set the connection string to a real SQL Server. See [Configuration](#) for more information.

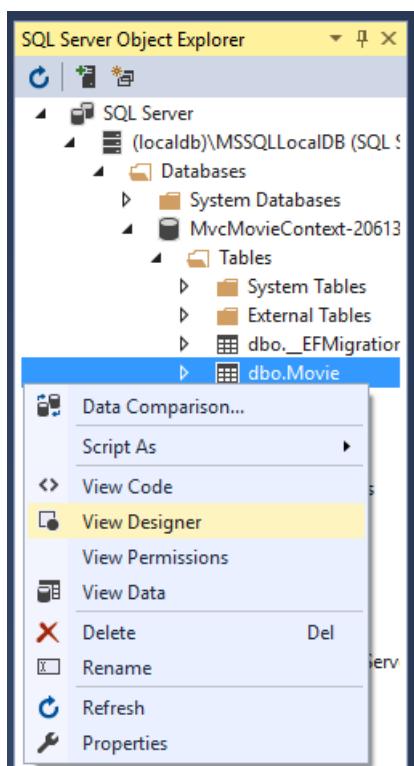

## SQL Server Express LocalDB

LocalDB is a lightweight version of the SQL Server Express Database Engine that's targeted for program development. LocalDB starts on demand and runs in user mode, so there's no complex configuration. By default, LocalDB database creates ".mdf" files in the `C:/Users/<user>` directory.

- From the **View** menu, open **SQL Server Object Explorer** (SSOX).

- Right click on the `Movie` table > **View Designer**

**dbo.Movie [Design]**

**Update | Script File: dbo.Movie.sql**

	Name	Data Type	Allow Nulls

**View Data**

**Properties**

The screenshot shows the 'MvcMovie' project in Microsoft Visual Studio. The 'dbo.Movie' table is open in the 'Data' view. The table structure is as follows:

	ID	Genre	Price	ReleaseDate	Title
▶	1	Comedy	1.99	11/18/2015 12:0...	When Harry Me...
▶	2	Comedy	2.99	1/11/2016 12:00...	Ghost Busters IV
*	3	Comedy	3.99	12/11/2015 12:0...	Ghost Busters 7
*	NULL	NULL	NULL	NULL	NULL

Below the table, the connection information is shown: Connection Re... | (localdb)\MSSQLLocalDB | REDMOND\riande | aspnet5-MvcMovie-8f261... . The status bar at the bottom indicates 3 Rows | Cell is Read Only | Ln 1 | Col 1.

## Seed the database

Create a new class named `SeedData` in the *Models* folder. Replace the generated code with the following:

```

using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using System;
using System.Linq;

namespace MvcMovie.Models
{
    public static class SeedData
    {
        public static void Initialize(IServiceProvider serviceProvider)
        {
            using (var context = new MvcMovieContext(
                serviceProvider.GetRequiredService<DbContextOptions<MvcMovieContext>>()))
            {
                // Look for any movies.
                if (context.Movie.Any())
                {
                    return; // DB has been seeded
                }

                context.Movie.AddRange(
                    new Movie
                    {
                        Title = "When Harry Met Sally",
                        ReleaseDate = DateTime.Parse("1989-1-11"),
                        Genre = "Romantic Comedy",
                        Price = 7.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters ",
                        ReleaseDate = DateTime.Parse("1984-3-13"),
                        Genre = "Comedy",
                        Price = 8.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters 2",
                        ReleaseDate = DateTime.Parse("1986-2-23"),
                        Genre = "Comedy",
                        Price = 9.99M
                    },
                    new Movie
                    {
                        Title = "Rio Bravo",
                        ReleaseDate = DateTime.Parse("1959-4-15"),
                        Genre = "Western",
                        Price = 3.99M
                    }
                );
                context.SaveChanges();
            }
        }
    }
}

```

If there are any movies in the DB, the seed initializer returns and no movies are added.

```
if (context.Movie.Any())
{
    return; // DB has been seeded.
}
```

## Add the seed initializer

Replace the contents of *Program.cs* with the following code:

```
using Microsoft.AspNetCore;
using Microsoft.AspNetCore.Hosting;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Logging;
using System;
using Microsoft.EntityFrameworkCore;
using MvcMovie.Models;
using MvcMovie;

namespace MvcMovie
{
    public class Program
    {
        public static void Main(string[] args)
        {
            var host = CreateWebHostBuilder(args).Build();

            using (var scope = host.Services.CreateScope())
            {
                var services = scope.ServiceProvider;

                try
                {
                    var context = services.GetRequiredService<MvcMovieContext>();
                    context.Database.Migrate();
                    SeedData.Initialize(services);
                }
                catch (Exception ex)
                {
                    var logger = services.GetRequiredService<ILogger<Program>>();
                    logger.LogError(ex, "An error occurred seeding the DB.");
                }
            }

            host.Run();
        }

        public static IWebHostBuilder CreateWebHostBuilder(string[] args) =>
            WebHost.CreateDefaultBuilder(args)
                .UseStartup<Startup>();
    }
}
```

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

Add the seed initializer to the `Main` method in the *Program.cs* file:

```

using Microsoft.AspNetCore;
using Microsoft.AspNetCore.Hosting;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Logging;
using MvcMovie.Models;
using System;

namespace MvcMovie
{
    public class Program
    {
        public static void Main(string[] args)
        {
            var host = BuildWebHost(args);

            using (var scope = host.Services.CreateScope())
            {
                var services = scope.ServiceProvider;

                try
                {
                    // Requires using MvcMovie.Models;
                    SeedData.Initialize(services);
                }
                catch (Exception ex)
                {
                    var logger = services.GetRequiredService<ILogger<Program>>();
                    logger.LogError(ex, "An error occurred seeding the DB.");
                }
            }

            host.Run();
        }

        public static IWebHost BuildWebHost(string[] args) =>
            WebHost.CreateDefaultBuilder(args)
                .UseStartup<Startup>()
                .Build();
    }
}

```

## Test the app

- Delete all the records in the DB. You can do this with the delete links in the browser or from SSOX.
- Force the app to initialize (call the methods in the `Startup` class) so the seed method runs. To force initialization, IIS Express must be stopped and restarted. You can do this with any of the following approaches:
  - Right click the IIS Express system tray icon in the notification area and tap **Exit** or **Stop Site**

- o If you were running VS in non-debug mode, press F5 to run in debug mode
- o If you were running VS in debug mode, stop the debugger and press F5

The app shows the seeded data.

A screenshot of a Microsoft Edge browser window. The title bar says '- Movie App' and the address bar shows 'localhost:5000/Movies'. The main content area displays a table titled 'Create New' with four columns: 'Title', 'ReleaseDate', 'Genre', and 'Price'. There are four rows of data:

Title	ReleaseDate	Genre	Price
When Harry Met Sally	1/11/1989 12:00:00 AM	Romantic Comedy	7.99
Ghostbusters	3/13/1984 12:00:00 AM	Comedy	8.99
Ghostbusters 2	2/23/1986 12:00:00 AM	Comedy	9.99

Each row has 'Edit | Details | Delete' links. At the bottom of the page, it says '© 2017 - MvcMovie'.

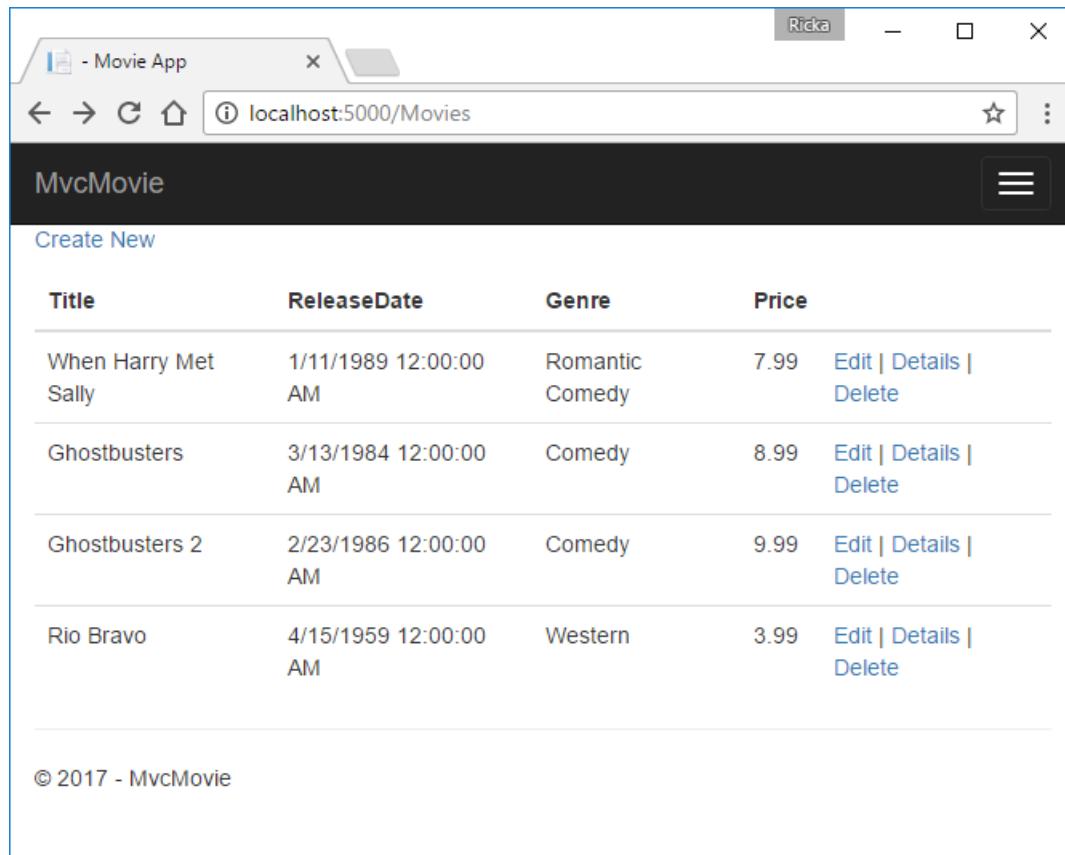

[PREVIOUS](#) [NEXT](#)

# Controller methods and views in ASP.NET Core

6/21/2018 • 10 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

We have a good start to the movie app, but the presentation isn't ideal. We don't want to see the time (12:00:00 AM in the image below) and **ReleaseDate** should be two words.

The screenshot shows a browser window titled "Movie App" with the URL "localhost:5000/Movies". The page is titled "MvcMovie" and has a "Create New" link. Below is a table listing four movies:

Title	ReleaseDate	Genre	Price	
When Harry Met Sally	1/11/1989 12:00:00 AM	Romantic Comedy	7.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Ghostbusters	3/13/1984 12:00:00 AM	Comedy	8.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Ghostbusters 2	2/23/1986 12:00:00 AM	Comedy	9.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Rio Bravo	4/15/1959 12:00:00 AM	Western	3.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

At the bottom left, it says "© 2017 - MvcMovie".

Open the *Models/Movie.cs* file and add the highlighted lines shown below:

```
using System;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace MvcMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }

        [Display(Name = "Release Date")]
        [DataType(DataType.Date)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }

        [Column(TypeName = "decimal(18, 2)")]
        public decimal Price { get; set; }
    }
}
```

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Threading.Tasks;

namespace MvcMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }

        [Display(Name = "Release Date")]
        [DataType(DataType.Date)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}

```

We cover [DataAnnotations](#) in the next tutorial. The [Display](#) attribute specifies what to display for the name of a field (in this case "Release Date" instead of "ReleaseDate"). The [DataType](#) attribute specifies the type of the data (Date), so the time information stored in the field isn't displayed.

The `[Column(TypeName = "decimal(18, 2)")]` data annotation is required so Entity Framework Core can correctly map `Price` to currency in the database. For more information, see [Data Types](#).

Browse to the `Movies` controller and hold the mouse pointer over an **Edit** link to see the target URL.

Genre	Price	Release Date	Title	
Romantic Comedy	7.99	1/11/1989	When Harry Met Sally	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	8.99	3/13/1984	Ghostbusters	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	9.99	2/23/1986	Ghostbusters 2	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Western	3.99	4/15/1959	Rio Bravo	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

© 2016 - MvcMovie

<http://localhost:1234/Movies/Edit/5>

The **Edit**, **Details**, and **Delete** links are generated by the Core MVC Anchor Tag Helper in the `Views/Movies/Index.cshtml` file.

```
<a asp-action="Edit" asp-route-id="@item.ID">Edit</a> |  
<a asp-action="Details" asp-route-id="@item.ID">Details</a> |  
<a asp-action="Delete" asp-route-id="@item.ID">Delete</a>  
</td>  
</tr>
```

Tag Helpers enable server-side code to participate in creating and rendering HTML elements in Razor files. In the code above, the `AnchorTagHelper` dynamically generates the HTML `href` attribute value from the controller action method and route id. You use **View Source** from your favorite browser or use the developer tools to examine the generated markup. A portion of the generated HTML is shown below:

```
<td>  
  <a href="/Movies/Edit/4"> Edit </a> |  
  <a href="/Movies/Details/4"> Details </a> |  
  <a href="/Movies/Delete/4"> Delete </a>  
</td>
```

Recall the format for **routing** set in the *Startup.cs* file:

```
app.UseMvc(routes =>  
{  
    routes.MapRoute(  
        name: "default",  
        template: "{controller=Home}/{action=Index}/{id?}");  
});
```

ASP.NET Core translates `http://localhost:1234/Movies/Edit/4` into a request to the `Edit` action method of the `Movies` controller with the parameter `Id` of 4. (Controller methods are also known as action methods.)

Tag Helpers are one of the most popular new features in ASP.NET Core. See [Additional resources](#) for more information.

Open the `Movies` controller and examine the two `Edit` action methods. The following code shows the `HTTP GET Edit` method, which fetches the movie and populates the edit form generated by the *Edit.cshtml* Razor file.

```
// GET: Movies/Edit/5  
public async Task<IActionResult> Edit(int? id)  
{  
    if (id == null)  
    {  
        return NotFound();  
    }  
  
    var movie = await _context.Movie.FindAsync(id);  
    if (movie == null)  
    {  
        return NotFound();  
    }  
    return View(movie);  
}
```

The following code shows the `HTTP POST Edit` method, which processes the posted movie values:

```

// POST: Movies/Edit/5
// To protect from overposting attacks, please enable the specific properties you want to bind to, for
// more details see http://go.microsoft.com/fwlink/?LinkId=317598.
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction("Index");
    }
    return View(movie);
}

```

```

// GET: Movies/Edit/5
public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }
    return View(movie);
}

```

The following code shows the `HTTP POST Edit` method, which processes the posted movie values:

```

// POST: Movies/Edit/5
// To protect from overposting attacks, please enable the specific properties you want to bind to, for
// more details see http://go.microsoft.com/fwlink/?LinkId=317598.
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction("Index");
    }
    return View(movie);
}

```

The `[Bind]` attribute is one way to protect against [over-posting](#). You should only include properties in the `[Bind]` attribute that you want to change. See [Protect your controller from over-posting](#) for more information.

[ViewModels](#) provide an alternative approach to prevent over-posting.

Notice the second `Edit` action method is preceded by the `[HttpPost]` attribute.

```
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction(nameof(Index));
    }
    return View(movie);
}
```

```

// POST: Movies/Edit/5
// To protect from overposting attacks, please enable the specific properties you want to bind to, for
// more details see http://go.microsoft.com/fwlink/?LinkId=317598.
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction("Index");
    }
    return View(movie);
}

```

The `[HttpPost]` attribute specifies that this `Edit` method can be invoked *only* for `POST` requests. You could apply the `[HttpGet]` attribute to the first edit method, but that's not necessary because `[HttpGet]` is the default.

The `[ValidateAntiForgeryToken]` attribute is used to [prevent forgery of a request](#) and is paired up with an anti-forgery token generated in the edit view file (`Views/Movies/Edit.cshtml`). The edit view file generates the anti-forgery token with the [Form Tag Helper](#).

```
<form asp-action="Edit">
```

The [Form Tag Helper](#) generates a hidden anti-forgery token that must match the `[ValidateAntiForgeryToken]` generated anti-forgery token in the `Edit` method of the Movies controller. For more information, see [Anti-Request Forgery](#).

The `[HttpGet Edit]` method takes the movie `ID` parameter, looks up the movie using the Entity Framework `SingleOrDefaultAsync` method, and returns the selected movie to the Edit view. If a movie cannot be found, `NotFound` (HTTP 404) is returned.

```
// GET: Movies/Edit/5
public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie.FindAsync(id);
    if (movie == null)
    {
        return NotFound();
    }
    return View(movie);
}
```

```
// GET: Movies/Edit/5
public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }
    return View(movie);
}
```

When the scaffolding system created the Edit view, it examined the `Movie` class and created code to render `<label>` and `<input>` elements for each property of the class. The following example shows the Edit view that was generated by the Visual Studio scaffolding system:

```

@model MvcMovie.Models.Movie

 @{
     ViewData["Title"] = "Edit";
 }

<h2>Edit</h2>

<form asp-action="Edit">
    <div class="form-horizontal">
        <h4>Movie</h4>
        <hr />
        <div asp-validation-summary="ModelOnly" class="text-danger"></div>
        <input type="hidden" asp-for="ID" />
        <div class="form-group">
            <label asp-for="Title" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Title" class="form-control" />
                <span asp-validation-for="Title" class="text-danger"></span>
            </div>
        </div>
        <div class="form-group">
            <label asp-for="ReleaseDate" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="ReleaseDate" class="form-control" />
                <span asp-validation-for="ReleaseDate" class="text-danger"></span>
            </div>
        </div>
        <div class="form-group">
            <label asp-for="Genre" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Genre" class="form-control" />
                <span asp-validation-for="Genre" class="text-danger"></span>
            </div>
        </div>
        <div class="form-group">
            <label asp-for="Price" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Price" class="form-control" />
                <span asp-validation-for="Price" class="text-danger"></span>
            </div>
        </div>
        <div class="form-group">
            <div class="col-md-offset-2 col-md-10">
                <input type="submit" value="Save" class="btn btn-default" />
            </div>
        </div>
    </div>
</form>

<div>
    <a asp-action="Index">Back to List</a>
</div>

@section Scripts {
    @{await Html.RenderPartialAsync("_ValidationScriptsPartial");}
}

```

Notice how the view template has a `@model MvcMovie.Models.Movie` statement at the top of the file.

`@model MvcMovie.Models.Movie` specifies that the view expects the model for the view template to be of type `Movie`.

The scaffolded code uses several Tag Helper methods to streamline the HTML markup. The - [Label Tag Helper](#) displays the name of the field ("Title", "ReleaseDate", "Genre", or "Price"). The [Input Tag Helper](#) renders an HTML `<input>` element. The [Validation Tag Helper](#) displays any validation messages associated with that property.

Run the application and navigate to the `/Movies` URL. Click an **Edit** link. In the browser, view the source for the page. The generated HTML for the `<form>` element is shown below.

```
<form action="/Movies/Edit/7" method="post">
    <div class="form-horizontal">
        <h4>Movie</h4>
        <hr />
        <div class="text-danger" />
        <input type="hidden" data-val="true" data-val-required="The ID field is required." id="ID" name="ID" value="7" />
        <div class="form-group">
            <label class="control-label col-md-2" for="Genre" />
            <div class="col-md-10">
                <input class="form-control" type="text" id="Genre" name="Genre" value="Western" />
                <span class="text-danger field-validation-valid" data-valmsg-for="Genre" data-valmsg-replace="true"></span>
            </div>
        </div>
        <div class="form-group">
            <label class="control-label col-md-2" for="Price" />
            <div class="col-md-10">
                <input class="form-control" type="text" data-val="true" data-val-number="The field Price must be a number." data-val-required="The Price field is required." id="Price" name="Price" value="3.99" />
                <span class="text-danger field-validation-valid" data-valmsg-for="Price" data-valmsg-replace="true"></span>
            </div>
        </div>
        <!-- Markup removed for brevity -->
        <div class="form-group">
            <div class="col-md-offset-2 col-md-10">
                <input type="submit" value="Save" class="btn btn-default" />
            </div>
        </div>
    </div>
    <input name="__RequestVerificationToken" type="hidden" value="CfDJ8Inyxp63fRFqUePGvuI5jGZsloJu1L7X9le1gy7NCI1SduCRx9jDQC1rV9pOTTmqUyXnJBXhmrjcUVDJyDUMm7-MF_9rK8aAZdRdl0ri7FmKVkRe_2v5LIHGKFcTjPrWPYnc9AdSbomki0SaTEg7RU" />
</form>
```

The `<input>` elements are in an `HTML <form>` element whose `action` attribute is set to post to the `/Movies/Edit/id` URL. The form data will be posted to the server when the `Save` button is clicked. The last line before the closing `</form>` element shows the hidden **XSRF** token generated by the [Form Tag Helper](#).

## Processing the POST Request

The following listing shows the `[HttpPost]` version of the `Edit` action method.

```
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction(nameof(Index));
    }
    return View(movie);
}
```

```

// POST: Movies/Edit/5
// To protect from overposting attacks, please enable the specific properties you want to bind to, for
// more details see http://go.microsoft.com/fwlink/?LinkId=317598.
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction("Index");
    }
    return View(movie);
}

```

The `[ValidateAntiForgeryToken]` attribute validates the hidden [XSRF](#) token generated by the anti-forgery token generator in the [Form Tag Helper](#)

The [model binding](#) system takes the posted form values and creates a `Movie` object that's passed as the `movie` parameter. The `ModelState.IsValid` method verifies that the data submitted in the form can be used to modify (edit or update) a `Movie` object. If the data is valid it's saved. The updated (edited) movie data is saved to the database by calling the `SaveChangesAsync` method of database context. After saving the data, the code redirects the user to the `Index` action method of the `MoviesController` class, which displays the movie collection, including the changes just made.

Before the form is posted to the server, client side validation checks any validation rules on the fields. If there are any validation errors, an error message is displayed and the form isn't posted. If JavaScript is disabled, you won't have client side validation but the server will detect the posted values that are not valid, and the form values will be redisplayed with error messages. Later in the tutorial we examine [Model Validation](#) in more detail. The [Validation Tag Helper](#) in the `Views/Movies/Edit.cshtml` view template takes care of displaying appropriate error messages.

All the `[HttpGet]` methods in the movie controller follow a similar pattern. They get a movie object (or list of objects, in the case of `Index`), and pass the object (model) to the view. The `Create` method passes an empty movie object to the `Create` view. All the methods that create, edit, delete, or otherwise modify data do so in the `[HttpPost]` overload of the method. Modifying data in an `HTTP GET` method is a security risk. Modifying data in an `HTTP GET` method also violates HTTP best practices and the architectural `REST` pattern, which specifies that GET requests shouldn't change the state of your application. In other words, performing a GET operation should be a safe operation that has no side effects and doesn't modify your persisted data.

# Add search to an ASP.NET Core MVC app

6/26/2018 • 7 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section you add search capability to the `Index` action method that lets you search movies by *genre* or *name*.

Update the `Index` method with the following code:

```
public async Task<IActionResult> Index(string searchString)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    return View(await movies.ToListAsync());
}
```

The first line of the `Index` action method creates a [LINQ](#) query to select the movies:

```
var movies = from m in _context.Movie
             select m;
```

The query is *only* defined at this point, it has **not** been run against the database.

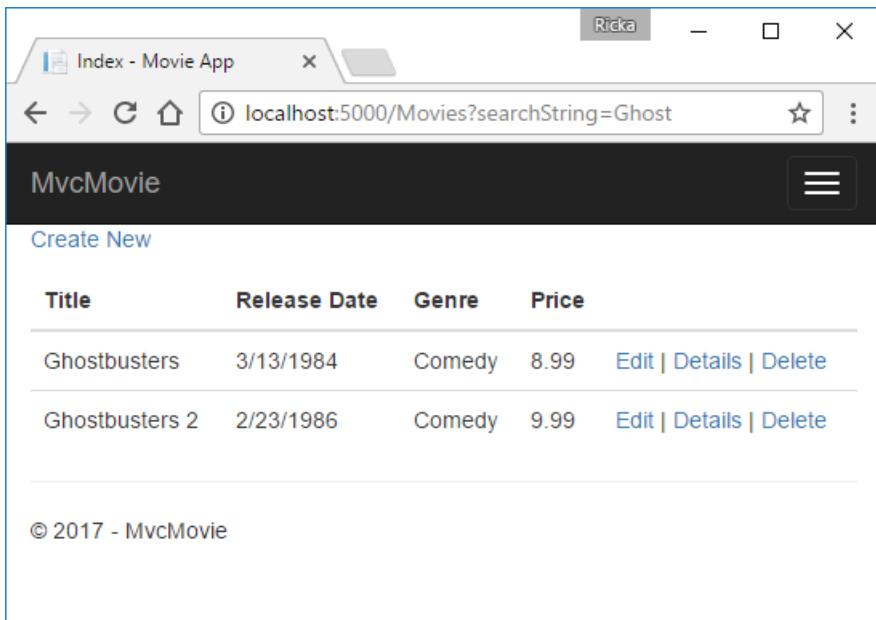

If the `searchString` parameter contains a string, the movies query is modified to filter on the value of the search string:

```
if (!String.IsNullOrEmpty(searchString))
{
    movies = movies.Where(s => s.Title.Contains(searchString));
}
```

The `s => s.Title.Contains()` code above is a [Lambda Expression](#). Lambdas are used in method-based [LINQ](#) queries as arguments to standard query operator methods such as the `Where` method or `Contains` (used in the code above). LINQ queries are not executed when they're defined or when they're modified by calling a method such as `Where`, `Contains` or `OrderBy`. Rather, query execution is deferred. That means that the evaluation of an expression is delayed until its realized value is actually iterated over or the `ToListAsync` method is called. For more information about deferred query execution, see [Query Execution](#).

Note: The `Contains` method is run on the database, not in the c# code shown above. The case sensitivity on the query depends on the database and the collation. On SQL Server, `Contains` maps to [SQL LIKE](#), which is case insensitive. In SQLite, with the default collation, it's case sensitive.

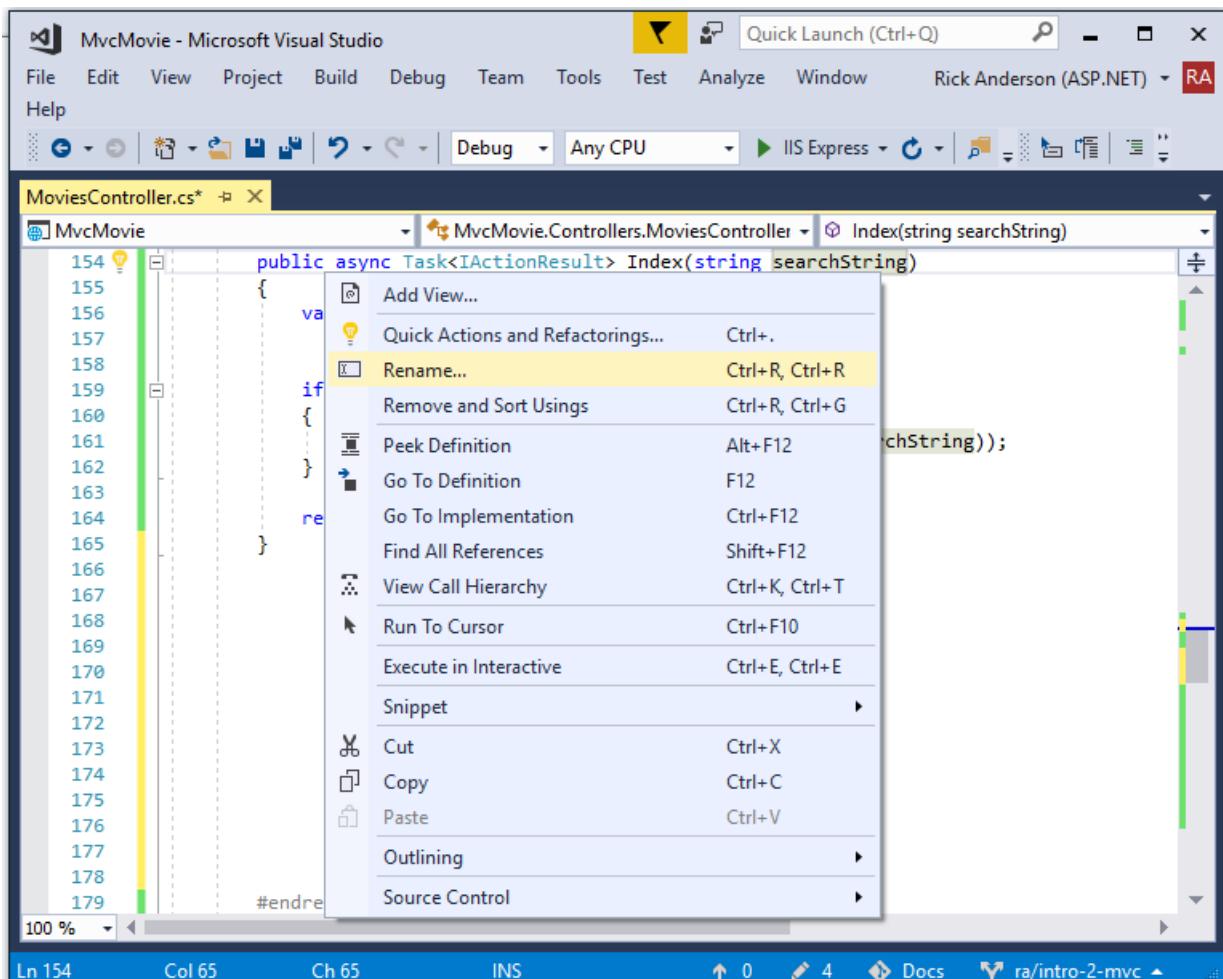

Navigate to `/Movies/Index`. Append a query string such as `?searchString=Ghost` to the URL. The filtered movies are displayed.

If you change the signature of the `Index` method to have a parameter named `id`, the `id` parameter will match the optional `{id}` placeholder for the default routes set in `Startup.cs`.

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

You can quickly rename the `searchString` parameter to `id` with the **rename** command. Right click on `searchString` > **Rename**.

The rename targets are highlighted.

```
public ActionResult Index(string searchString)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    return View(movies);
}
```

Change the parameter to `id` and all occurrences of `searchString` change to `id`.

```
public ActionResult Index(string id)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(id))
    {
        movies = movies.Where(s => s.Title.Contains(id));
    }

    return View(movies);
}
```

The previous `Index` method:

```

public async Task<IActionResult> Index(string searchString)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    return View(await movies.ToListAsync());
}

```

The updated `Index` method with `id` parameter:

```

public async Task<IActionResult> Index(string id)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(id))
    {
        movies = movies.Where(s => s.Title.Contains(id));
    }

    return View(await movies.ToListAsync());
}

```

You can now pass the search title as route data (a URL segment) instead of as a query string value.

Genre	Price	Release Date	Title	
Comedy	8.99	3/13/1984	Ghostbusters	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	9.99	2/23/1986	Ghostbusters 2	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

© 2015 - MvcMovie

However, you can't expect users to modify the URL every time they want to search for a movie. So now you'll add UI elements to help them filter movies. If you changed the signature of the `Index` method to test how to pass the route-bound `ID` parameter, change it back so that it takes a parameter named `searchString`:

```

public async Task<IActionResult> Index(string searchString)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    return View(await movies.ToListAsync());
}

```

Open the `Views/Movies/Index.cshtml` file, and add the `<form>` markup highlighted below:

```

        ViewData["Title"] = "Index";
    }

<h2>Index</h2>

<p>
    <a asp-action="Create">Create New</a>
</p>

<form asp-controller="Movies" asp-action="Index">
    <p>
        Title: <input type="text" name="SearchString">
        <input type="submit" value="Filter" />
    </p>
</form>

<table class="table">
    <thead>

```

The HTML `<form>` tag uses the [Form Tag Helper](#), so when you submit the form, the filter string is posted to the `Index` action of the movies controller. Save your changes and then test the filter.

Genre	Price	Release Date	Title	
Romantic Comedy	7.99	1/11/1989	When Harry Met Sally	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	8.99	3/13/1984	Ghostbusters	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	9.99	2/23/1986	Ghostbusters 2	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Western	3.99	4/15/1959	Rio Bravo	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

© 2016 - MvcMovie

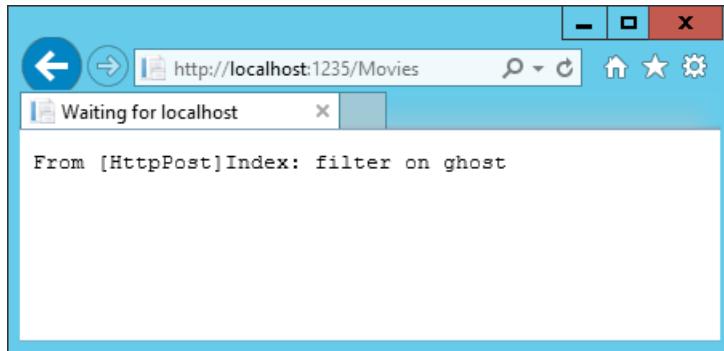

There's no `[HttpPost]` overload of the `Index` method as you might expect. You don't need it, because the method isn't changing the state of the app, just filtering data.

You could add the following `[HttpPost] Index` method.

```
[HttpPost]
public string Index(string searchString, bool notUsed)
{
    return "From [HttpPost]Index: filter on " + searchString;
}
```

The `notUsed` parameter is used to create an overload for the `Index` method. We'll talk about that later in the tutorial.

If you add this method, the action invoker would match the `[HttpPost] Index` method, and the `[HttpPost] Index` method would run as shown in the image below.

However, even if you add this `[HttpPost]` version of the `Index` method, there's a limitation in how this has all been implemented. Imagine that you want to bookmark a particular search or you want to send a link to friends that they can click in order to see the same filtered list of movies. Notice that the URL for the HTTP POST request is the same as the URL for the GET request (`localhost:xxxxx/Movies/Index`) -- there's no search information in the URL. The search string information is sent to the server as a [form field value](#). You can verify that with the browser Developer tools or the excellent [Fiddler tool](#). The image below shows the Chrome browser Developer tools:

The screenshot shows the Chrome DevTools Network tab for a 'Movie App' at `localhost:5000/Movies`. A red box highlights the 'Movies' entry in the list, which corresponds to the search term entered in the application. Another red box highlights the 'Request Headers' section, showing the search parameter and the XSRF token. A third red box highlights the 'Form Data' section, showing the search parameter and the XSRF token.

**Form Data:**

- SearchString: Ghost
- \_RequestVerificationToken: CfDJ8B98MxUFL5pAq2aeCj59HP1g2HXMD176MabW7uuk20AGre8b3y0NufBTMAjxmJCjRFe-2sF50PVla72IyfcA9Pao3muZ0f4jtjDND1XEagdJk\_g67wBX12qOKI7DLD980GjMjBB\_-5rvRhJuQCroPRw

You can see the search parameter and [XSRF](#) token in the request body. Note, as mentioned in the previous tutorial, the [Form Tag Helper](#) generates an [XSRF](#) anti-forgery token. We're not modifying data, so we don't need to validate the token in the controller method.

Because the search parameter is in the request body and not the URL, you can't capture that search information to bookmark or share with others. We'll fix this by specifying the request should be `HTTP GET`.

Notice how intelliSense helps us update the markup.

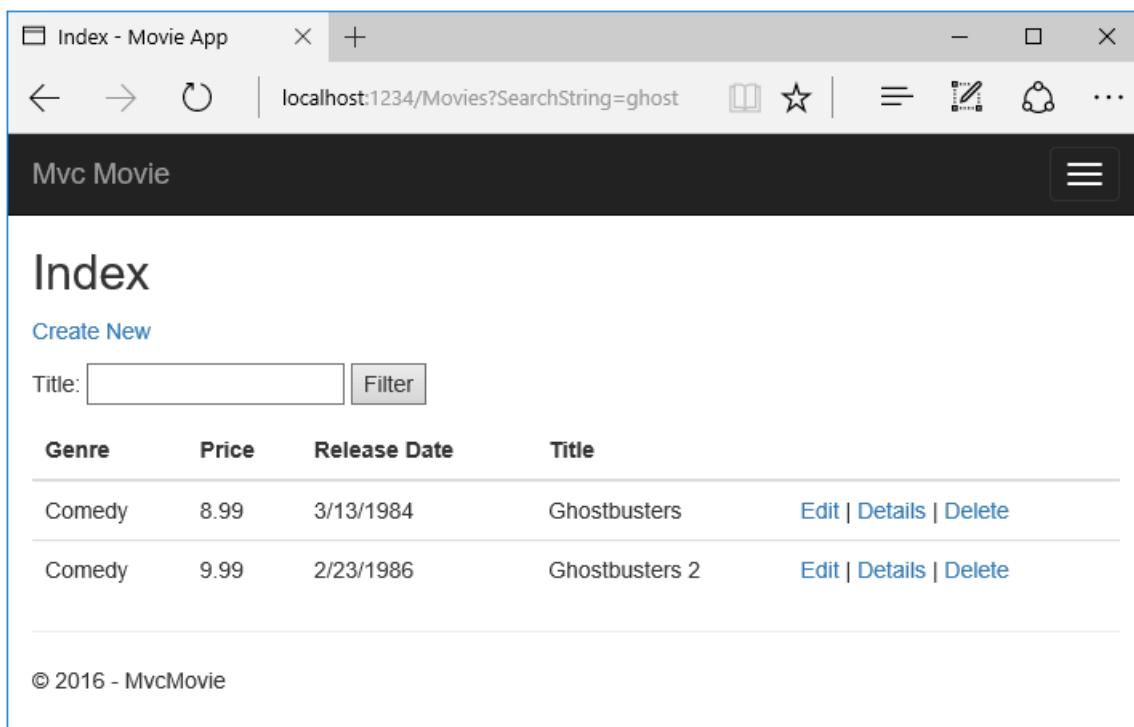

```
<form asp-controller="Movies" asp-action="Index" method="get">
  <p>
    Title: <input type="text" name="SearchString" />
    <input type="submit" value="Filter" />
  </p>
</form>
```

```
<form asp-controller="Movies" asp-action="Index" method="get">
  <p>
    Title: <input type="text" name="SearchString" />
    <input type="submit" value="Filter" />
  </p>
</form>
```

Notice the distinctive font in the `<form>` tag. That distinctive font indicates the tag is supported by Tag Helpers.

```
<form asp-controller="Movies" asp-action="Index">
  <p>
    Title: <input type="text" name="SearchString" />
    <input type="submit" value="Filter" />
  </p>
</form>
```

Now when you submit a search, the URL contains the search query string. Searching will also go to the `HttpGet Index` action method, even if you have a `HttpPost Index` method.

The following markup shows the change to the `form` tag:

```
<form asp-controller="Movies" asp-action="Index" method="get">
```

## Adding Search by genre

Add the following `MovieGenreViewModel` class to the *Models* folder:

```

using Microsoft.AspNetCore.Mvc.Rendering;
using System.Collections.Generic;

namespace MvcMovie.Models
{
    public class MovieGenreViewModel
    {
        public List<Movie> movies;
        public SelectList genres;
        public string movieGenre { get; set; }
    }
}

```

The movie-genre view model will contain:

- A list of movies.
- A `SelectList` containing the list of genres. This will allow the user to select a genre from the list.
- `movieGenre`, which contains the selected genre.

Replace the `Index` method in `MoviesController.cs` with the following code:

```

// Requires using Microsoft.AspNetCore.Mvc.Rendering;
public async Task<IActionResult> Index(string movieGenre, string searchString)
{
    // Use LINQ to get list of genres.
    IQueryable<string> genreQuery = from m in _context.Movie
                                         orderby m.Genre
                                         select m.Genre;

    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    if (!String.IsNullOrEmpty(movieGenre))
    {
        movies = movies.Where(x => x.Genre == movieGenre);
    }

    var movieGenreVM = new MovieGenreViewModel();
    movieGenreVM.genres = new SelectList(await genreQuery.Distinct().ToListAsync());
    movieGenreVM.movies = await movies.ToListAsync();

    return View(movieGenreVM);
}

```

The following code is a `LINQ` query that retrieves all the genres from the database.

```

// Use LINQ to get list of genres.
IQueryable<string> genreQuery = from m in _context.Movie
                                         orderby m.Genre
                                         select m.Genre;

```

The `SelectList` of genres is created by projecting the distinct genres (we don't want our select list to have duplicate genres).

```
movieGenreVM.genres = new SelectList(await genreQuery.Distinct().ToListAsync())
```

## Adding search by genre to the Index view

Update `Index.cshtml` as follows:

```

@model MvcMovie.Models.MovieGenreViewModel

 @{
     ViewData["Title"] = "Index";
 }

<h2>Index</h2>

<p>
    <a asp-action="Create">Create New</a>
</p>

<form asp-controller="Movies" asp-action="Index" method="get">
    <p>
        <select asp-for="movieGenre" asp-items="Model.genres">
            <option value="">All</option>
        </select>

        Title: <input type="text" name="SearchString">
        <input type="submit" value="Filter" />
    </p>
</form>

<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Title)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].ReleaseDate)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Genre)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Price)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
        @foreach (var item in Model.movies)
        {
            <tr>
                <td>
                    @Html.DisplayFor(modelItem => item.Title)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.ReleaseDate)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Genre)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Price)
                </td>
                <td>
                    <a asp-action="Edit" asp-route-id="@item.ID">Edit</a> |
                    <a asp-action="Details" asp-route-id="@item.ID">Details</a> |
                    <a asp-action="Delete" asp-route-id="@item.ID">Delete</a>
                </td>
            </tr>
        }
    </tbody>
</table>

```

Examine the lambda expression used in the following HTML Helper:

```
@Html.DisplayNameFor(model => model.movies[0].Title)
```

In the preceding code, the `DisplayNameFor` HTML Helper inspects the `Title` property referenced in the lambda expression to determine the display name. Since the lambda expression is inspected rather than evaluated, you don't receive an access violation when `model`, `model.movies`, or `model.movies[0]` are `null` or empty. When the lambda expression is evaluated (for example, `@Html.DisplayFor(modelItem => item.Title)`), the model's property values are evaluated.

Test the app by searching by genre, by movie title, and by both.

[PREVIOUS](#)

[NEXT](#)

# Add a new field to an ASP.NET Core MVC app

6/26/2018 • 4 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section you'll use [Entity Framework](#) Code First Migrations to add a new field to the model and migrate that change to the database.

When you use EF Code First to automatically create a database, Code First adds a table to the database to help track whether the schema of the database is in sync with the model classes it was generated from. If they aren't in sync, EF throws an exception. This makes it easier to find inconsistent database/code issues.

## Adding a Rating Property to the Movie Model

Open the `Models/Movie.cs` file and add a `Rating` property:

```
public class Movie
{
    public int ID { get; set; }
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }
    public string Genre { get; set; }

    [Column(TypeName = "decimal(18, 2)")]
    public decimal Price { get; set; }
    public string Rating { get; set; }
}
```

```
public class Movie
{
    public int ID { get; set; }
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }
    public string Genre { get; set; }
    public decimal Price { get; set; }
    public string Rating { get; set; }
}
```

Build the app (Ctrl+Shift+B).

Because you've added a new field to the `Movie` class, you also need to update the binding white list so this new property will be included. In `MoviesController.cs`, update the `[Bind]` attribute for both the `Create` and `Edit` action methods to include the `Rating` property:

```
[Bind("ID,Title,ReleaseDate,Genre,Price,Rating")]
```

You also need to update the view templates in order to display, create and edit the new `Rating` property in the browser view.

Edit the `/Views/Movies/Index.cshtml` file and add a `Rating` field:

```
<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Title)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].ReleaseDate)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Genre)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Price)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Rating)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
        @foreach (var item in Model.movies)
        {
            <tr>
                <td>
                    @Html.DisplayFor(modelItem => item.Title)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.ReleaseDate)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Genre)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Price)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Rating)
                </td>
                <td>
```

Update the `/Views/Movies/Create.cshtml` with a `Rating` field. You can copy/paste the previous "form group" and let intelliSense help you update the fields. IntelliSense works with [Tag Helpers](#). Note: In the RTM verison of Visual Studio 2017 you need to install the [Razor Language Services](#) for Razor intelliSense. This will be fixed in the next release.

```

        </div>
        <div class="form-group">
            <label asp-for="Title" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Title" class="form-control" />
                <span asp-validation-for="Title" class="text-danger" />
            </div>
        </div>
        <div class="form-group">
            <label asp-for="R" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="R" class="form-control" />
                <span asp-validation-for="R" class="text-danger" />
            </div>
        </div>
        <div class="form-group">
            <label asp-for="Rating" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Rating" type="text" class="form-control" />
                <span asp-validation-for="Rating" class="text-danger" />
            </div>
        </div>
    </div>
</form>

```

The app won't work until we update the DB to include the new field. If you run it now, you'll get the following `SqlException`:

```
SqlException: Invalid column name 'Rating'.
```

You're seeing this error because the updated Movie model class is different than the schema of the Movie table of the existing database. (There's no Rating column in the database table.)

There are a few approaches to resolving the error:

1. Have the Entity Framework automatically drop and re-create the database based on the new model class schema. This approach is very convenient early in the development cycle when you are doing active development on a test database; it allows you to quickly evolve the model and database schema together. The downside, though, is that you lose existing data in the database — so you don't want to use this approach on a production database! Using an initializer to automatically seed a database with test data is often a productive way to develop an application.
2. Explicitly modify the schema of the existing database so that it matches the model classes. The advantage of this approach is that you keep your data. You can make this change either manually or by creating a database change script.
3. Use Code First Migrations to update the database schema.

For this tutorial, we'll use Code First Migrations.

Update the `SeedData` class so that it provides a value for the new column. A sample change is shown below, but you'll want to make this change for each `new Movie`.

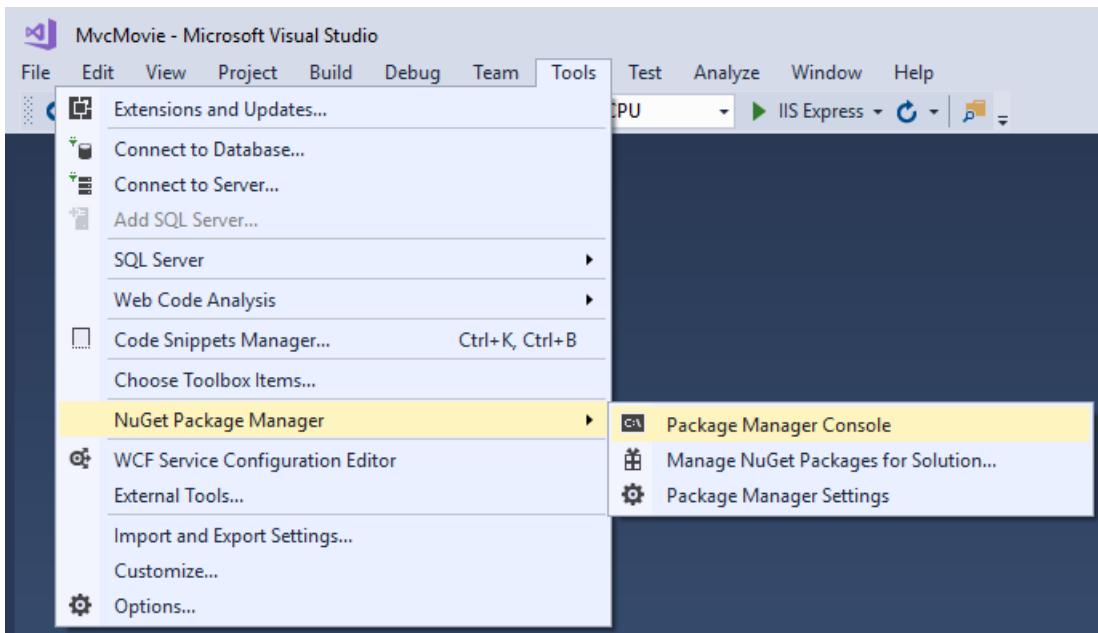

```

new Movie
{
    Title = "When Harry Met Sally",
    ReleaseDate = DateTime.Parse("1989-1-11"),
    Genre = "Romantic Comedy",
    Rating = "R",
    Price = 7.99M
},

```

Build the solution.

From the **Tools** menu, select **NuGet Package Manager > Package Manager Console**.

In the PMC, enter the following commands:

```
Add-Migration Rating  
Update-Database
```

The `Add-Migration` command tells the migration framework to examine the current `Movie` model with the current `Movie` DB schema and create the necessary code to migrate the DB to the new model. The name "Rating" is arbitrary and is used to name the migration file. It's helpful to use a meaningful name for the migration file.

If you delete all the records in the DB, the initialize will seed the DB and include the `Rating` field. You can do this with the delete links in the browser or from SSOX.

Run the app and verify you can create/edit/display movies with a `Rating` field. You should also add the `Rating` field to the `Edit`, `Details`, and `Delete` view templates.

[PREVIOUS](#) [NEXT](#)

# Add validation to an ASP.NET Core MVC app

6/26/2018 • 10 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section you'll add validation logic to the `Movie` model, and you'll ensure that the validation rules are enforced any time a user creates or edits a movie.

## Keeping things DRY

One of the design tenets of MVC is [DRY](#) ("Don't Repeat Yourself"). ASP.NET MVC encourages you to specify functionality or behavior only once, and then have it be reflected everywhere in an app. This reduces the amount of code you need to write and makes the code you do write less error prone, easier to test, and easier to maintain.

The validation support provided by MVC and Entity Framework Core Code First is a good example of the DRY principle in action. You can declaratively specify validation rules in one place (in the model class) and the rules are enforced everywhere in the app.

## Adding validation rules to the movie model

Open the `Movie.cs` file. DataAnnotations provides a built-in set of validation attributes that you apply declaratively to any class or property. (It also contains formatting attributes like `DataType` that help with formatting and don't provide any validation.)

Update the `Movie` class to take advantage of the built-in `Required`, `StringLength`, `RegularExpression`, and `Range` validation attributes.

```
public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3)]
    [Required]
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [Range(1, 100)]
    [DataType(DataType.Currency)]
    [Column(TypeName = "decimal(18, 2)")]
    public decimal Price { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z\s-]*$")]
    [Required]
    [StringLength(30)]
    public string Genre { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z0-9\s-]*$")]
    [StringLength(5)]
    [Required]
    public string Rating { get; set; }
}
```

```

public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3)]
    [Required]
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [Range(1, 100)]
    [DataType(DataType.Currency)]
    public decimal Price { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z''"\s-]*$")]
    [Required]
    [StringLength(30)]
    public string Genre { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z0-9"""\s-]*$")]
    [StringLength(5)]
    [Required]
    public string Rating { get; set; }
}

```

The validation attributes specify behavior that you want to enforce on the model properties they're applied to. The `Required` and `MinimumLength` attributes indicate that a property must have a value, but nothing prevents a user from entering white space to satisfy this validation. The `RegularExpression` attribute is used to limit what characters can be input. In the code above, `Genre` and `Rating` must use only letters (First letter uppercase, white space, numbers and special characters are not allowed). The `Range` attribute constrains a value to within a specified range. The `StringLength` attribute lets you set the maximum length of a string property, and optionally its minimum length. Value types (such as `decimal`, `int`, `float`, `DateTime`) are inherently required and don't need the `[Required]` attribute.

Having validation rules automatically enforced by ASP.NET helps make your app more robust. It also ensures that you can't forget to validate something and inadvertently let bad data into the database.

## Validation Error UI in MVC

Run the app and navigate to the Movies controller.

Tap the **Create New** link to add a new movie. Fill out the form with some invalid values. As soon as jQuery client side validation detects the error, it displays an error message.

The screenshot shows a browser window titled "Create - Movie App" with the URL "localhost:5000/Movies/Cre". The page is titled "MvcMovie" and has a "Create" heading. Below it is a "Movie" section. The form contains five fields: "Title", "Release Date", "Genre", "Price", and "Rating". Each field has a validation error message below it. The "Title" field says "The field Title must be a string with a minimum length of 3 and a maximum length of 60.". The "Genre" field says "The Genre field is required.". The "Price" field says "The field Price must be a number.". The "Rating" field says "The field Rating must match the regular expression ^[A-Z]+[a-zA-Z]+\s\*\\$.". At the bottom left is a "Create" button, and at the bottom center is a link "Back to List".

#### NOTE

You may not be able to enter decimal commas in the `Price` field. To support [jQuery validation](#) for non-US-English locales that use a comma (",") for a decimal point, and non US-English date formats, you must take steps to globalize your app. This [GitHub issue 4076](#) for instructions on adding decimal comma.

Notice how the form has automatically rendered an appropriate validation error message in each field containing an invalid value. The errors are enforced both client-side (using JavaScript and jQuery) and server-side (in case a user has JavaScript disabled).

A significant benefit is that you didn't need to change a single line of code in the `MoviesController` class or in the `Create.cshtml` view in order to enable this validation UI. The controller and views you created earlier in this tutorial automatically picked up the validation rules that you specified by using validation attributes on the properties of the `Movie` model class. Test validation using the `Edit` action method, and the same validation is applied.

The form data isn't sent to the server until there are no client side validation errors. You can verify this by putting a break point in the `HTTP Post` method, by using the [Fiddler tool](#), or the [F12 Developer tools](#).

## How validation works

You might wonder how the validation UI was generated without any updates to the code in the controller or views. The following code shows the two `Create` methods.

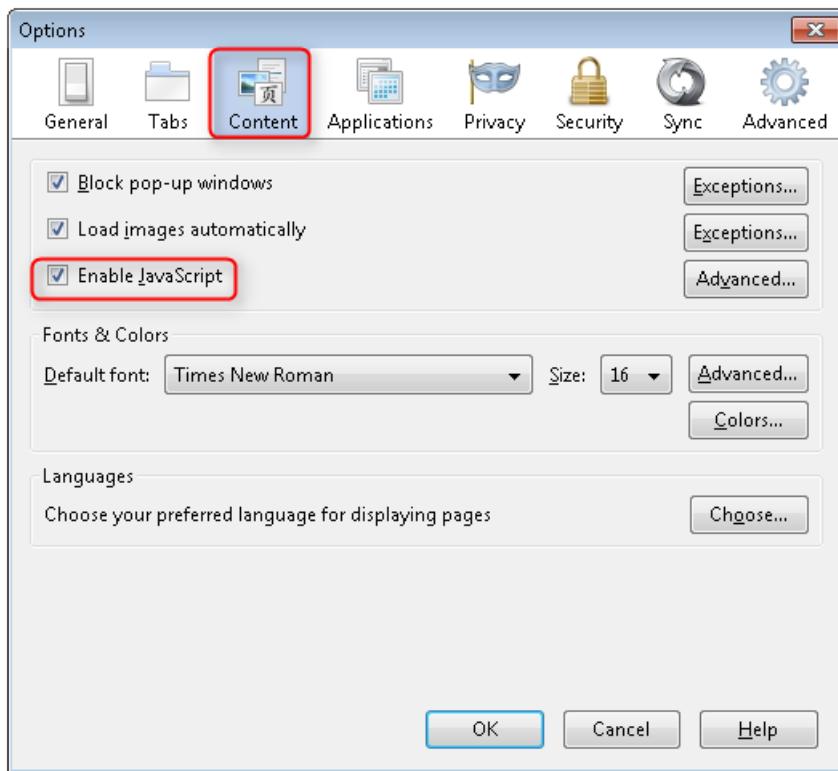

```
// GET: Movies/Create
public IActionResult Create()
{
    return View();
}

// POST: Movies/Create
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Create(
    [Bind("ID,Title,ReleaseDate,Genre,Price, Rating")] Movie movie)
{
    if (ModelState.IsValid)
    {
        _context.Add(movie);
        await _context.SaveChangesAsync();
        return RedirectToAction("Index");
    }
    return View(movie);
}
```

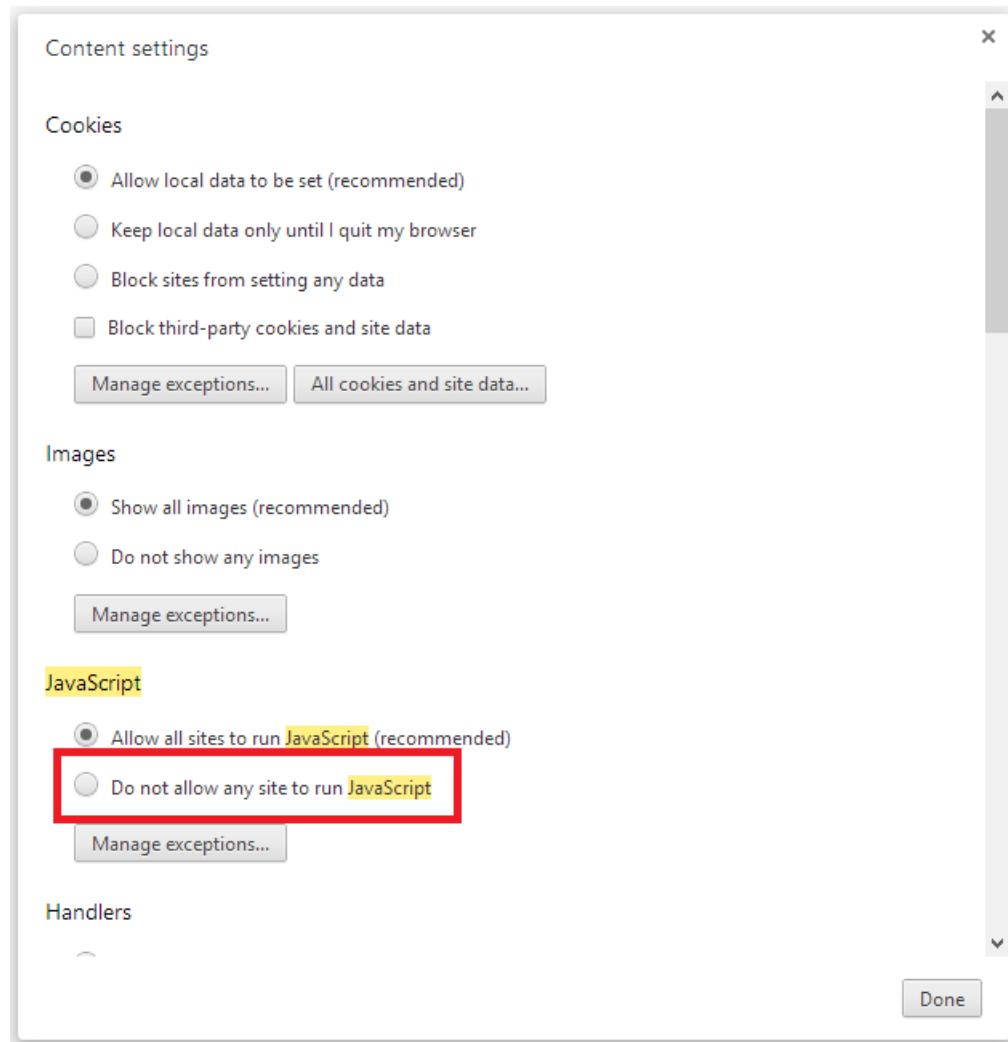

The first (HTTP GET) `Create` action method displays the initial Create form. The second (`[HttpPost]`) version handles the form post. The second `Create` method (The `[HttpPost]` version) calls `ModelState.IsValid` to check whether the movie has any validation errors. Calling this method evaluates any validation attributes that have been applied to the object. If the object has validation errors, the `Create` method re-displays the form. If there are no errors, the method saves the new movie in the database. In our movie example, the form isn't posted to the server when there are validation errors detected on the client side; the second `Create` method is never called when there are client side validation errors. If you disable JavaScript in your browser, client validation is disabled and you can test the HTTP POST `Create` method `ModelState.IsValid` detecting any validation errors.

You can set a break point in the `[HttpPost] Create` method and verify the method is never called, client side validation won't submit the form data when validation errors are detected. If you disable JavaScript in your browser, then submit the form with errors, the break point will be hit. You still get full validation without JavaScript.

The following image shows how to disable JavaScript in the FireFox browser.

The following image shows how to disable JavaScript in the Chrome browser.

After you disable JavaScript, post invalid data and step through the debugger.

```

74         // POST: Movies/Create
75         // To protect from overposting attacks, please enable t
76         // more details see http://go.microsoft.com/fwlink/?LinkID=147393
77         [HttpPost]
78         [ValidateAntiForgeryToken]
79         0 references
80         public async Task<ActionResult> Create([Bind("ID,Title",
81                                         false)]
81             if (ModelState.IsValid)
82             {
83                 _context.Add(movie);
84                 await _context.SaveChangesAsync();
85                 return RedirectToAction("Index");
86             }
87             return View(movie);
88         }
89

```

Below is portion of the *Create.cshtml* view template that you scaffolded earlier in the tutorial. It's used by the action methods shown above both to display the initial form and to redisplay it in the event of an error.

```

<form asp-action="Create">
    <div class="form-horizontal">
        <h4>Movie</h4>
        <hr />

        <div asp-validation-summary="ModelOnly" class="text-danger"></div>
        <div class="form-group">
            <label asp-for="Title" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Title" class="form-control" />
                <span asp-validation-for="Title" class="text-danger"></span>
            </div>
        </div>
    </div>

    @*Markup removed for brevity.*@
    </div>
</form>

```

The [Input Tag Helper](#) uses the [DataAnnotations](#) attributes and produces HTML attributes needed for jQuery Validation on the client side. The [Validation Tag Helper](#) displays validation errors. See [Validation](#) for more information.

What's really nice about this approach is that neither the controller nor the `create` view template knows anything about the actual validation rules being enforced or about the specific error messages displayed. The validation rules and the error strings are specified only in the `Movie` class. These same validation rules are automatically applied to the `Edit` view and any other views templates you might create that edit your model.

When you need to change validation logic, you can do so in exactly one place by adding validation attributes to the model (in this example, the `Movie` class). You won't have to worry about different parts of the application being inconsistent with how the rules are enforced — all validation logic will be defined in one place and used everywhere. This keeps the code very clean, and makes it easy to maintain and evolve. And it means that you'll be fully honoring the DRY principle.

## Using DataType Attributes

Open the `Movie.cs` file and examine the `Movie` class. The `System.ComponentModel.DataAnnotations` namespace provides formatting attributes in addition to the built-in set of validation attributes. We've already applied a `DataType` enumeration value to the release date and to the price fields. The following code shows the `ReleaseDate` and `Price` properties with the appropriate `DataType` attribute.

```
[Display(Name = "Release Date")]
[DataType(DataType.Date)]
public DateTime ReleaseDate { get; set; }

[Range(1, 100)]
[DataType(DataType.Currency)]
public decimal Price { get; set; }
```

The `DataType` attributes only provide hints for the view engine to format the data (and supplies elements/attributes such as `<a>` for URL's and `<a href="mailto:EmailAddress.com">` for email. You can use the `RegularExpression` attribute to validate the format of the data. The `DataType` attribute is used to specify a data type that's more specific than the database intrinsic type, they're not validation attributes. In this case we only want to keep track of the date, not the time. The `DataType` Enumeration provides for many data types, such as Date, Time, PhoneNumber, Currency, EmailAddress and more. The `DataType` attribute can also enable the application to automatically provide type-specific features. For example, a `mailto:` link can be created for `DataType.EmailAddress`, and a date selector can be provided for `DataType.Date` in browsers that support HTML5. The `DataType` attributes emits HTML 5 `data-` (pronounced data dash) attributes that HTML 5 browsers can understand. The `DataType` attributes do **not** provide any validation.

`DataType.Date` doesn't specify the format of the date that's displayed. By default, the data field is displayed according to the default formats based on the server's `CultureInfo`.

The `DisplayFormat` attribute is used to explicitly specify the date format:

```
[DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
public DateTime ReleaseDate { get; set; }
```

The `ApplyFormatInEditMode` setting specifies that the formatting should also be applied when the value is displayed in a text box for editing. (You might not want that for some fields — for example, for currency values, you probably don't want the currency symbol in the text box for editing.)

You can use the `DisplayFormat` attribute by itself, but it's generally a good idea to use the `DataType` attribute. The `DataType` attribute conveys the semantics of the data as opposed to how to render it on a screen, and provides the following benefits that you don't get with `DisplayFormat`:

- The browser can enable HTML5 features (for example to show a calendar control, the locale-appropriate currency symbol, email links, etc.)
- By default, the browser will render data using the correct format based on your locale.
- The `DataType` attribute can enable MVC to choose the right field template to render the data (the `DisplayFormat` if used by itself uses the string template).

#### NOTE

jQuery validation doesn't work with the `Range` attribute and `DateTime`. For example, the following code will always display a client side validation error, even when the date is in the specified range:

```
[Range(typeof(DateTime), "1/1/1966", "1/1/2020")]
```

You will need to disable jQuery date validation to use the `Range` attribute with `DateTime`. It's generally not a good practice to compile hard dates in your models, so using the `Range` attribute and `DateTime` is discouraged.

The following code shows combining attributes on one line:

```

public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3)]
    public string Title { get; set; }

    [Display(Name = "Release Date"), DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [RegularExpression(@"^([A-Z][a-zA-Z\s-]*$"), Required, StringLength(30)]
    public string Genre { get; set; }

    [Range(1, 100), DataType(DataType.Currency)]
    [Column(TypeName = "decimal(18, 2)")]
    public decimal Price { get; set; }

    [RegularExpression(@"^([A-Z][a-zA-Z0-9\s-]*$"), StringLength(5)]
    public string Rating { get; set; }
}

```

```

public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3), Required]
    public string Title { get; set; }

    [Display(Name = "Release Date"), DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [RegularExpression(@"^([A-Z][a-zA-Z\s-]*$"), Required, StringLength(30)]
    public string Genre { get; set; }

    [Range(1, 100), DataType(DataType.Currency)]
    public decimal Price { get; set; }

    [RegularExpression(@"^([A-Z][a-zA-Z0-9\s-]*$"), Required, StringLength(5)]
    public string Rating { get; set; }
}

```

In the next part of the series, we'll review the application and make some improvements to the automatically generated `Details` and `Delete` methods.

# Examine the Details and Delete methods of an ASP.NET Core app

6/21/2018 • 3 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

Open the Movie controller and examine the `Details` method:

```
// GET: Movies/Details/5
public async Task<IActionResult> Details(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .FirstOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}
```

```
// GET: Movies/Details/5
public async Task<IActionResult> Details(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .SingleOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}
```

The MVC scaffolding engine that created this action method adds a comment showing an HTTP request that invokes the method. In this case it's a GET request with three URL segments, the `Movies` controller, the `Details` method and an `id` value. Recall these segments are defined in *Startup.cs*.

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

EF makes it easy to search for data using the `SingleOrDefaultAsync` method. An important security feature built into the method is that the code verifies that the search method has found a movie before it tries to do anything with it. For example, a hacker could introduce errors into the site by changing the URL created by the links from `http://localhost:xxxx/Movies/Details/1` to something like `http://localhost:xxxx/Movies/Details/12345` (or some other value that doesn't represent an actual movie). If you didn't check for a null movie, the app would throw an exception.

Examine the `Delete` and `DeleteConfirmed` methods.

```
// GET: Movies/Delete/5
public async Task<IActionResult> Delete(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .FirstOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}

// POST: Movies/Delete/5
[HttpPost, ActionName("Delete")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> DeleteConfirmed(int id)
{
    var movie = await _context.Movie.FindAsync(id);
    _context.Movie.Remove(movie);
    await _context.SaveChangesAsync();
    return RedirectToAction(nameof(Index));
}
```

```

// GET: Movies/Delete/5
public async Task<IActionResult> Delete(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .SingleOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}

// POST: Movies/Delete/5
[HttpPost, ActionName("Delete")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> DeleteConfirmed(int id)
{
    var movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);
    _context.Movie.Remove(movie);
    await _context.SaveChangesAsync();
    return RedirectToAction("Index");
}

```

Note that the `HTTP GET Delete` method doesn't delete the specified movie, it returns a view of the movie where you can submit (`HttpPost`) the deletion. Performing a delete operation in response to a GET request (or for that matter, performing an edit operation, create operation, or any other operation that changes data) opens up a security hole.

The `[HttpPost]` method that deletes the data is named `DeleteConfirmed` to give the HTTP POST method a unique signature or name. The two method signatures are shown below:

```

// GET: Movies/Delete/5
public async Task<IActionResult> Delete(int? id)
{
```

```

// POST: Movies/Delete/5
[HttpPost, ActionName("Delete")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> DeleteConfirmed(int id)
{
```

The common language runtime (CLR) requires overloaded methods to have a unique parameter signature (same method name but different list of parameters). However, here you need two `Delete` methods -- one for GET and one for POST -- that both have the same parameter signature. (They both need to accept a single integer as a parameter.)

There are two approaches to this problem, one is to give the methods different names. That's what the scaffolding mechanism did in the preceding example. However, this introduces a small problem: ASP.NET maps segments of a URL to action methods by name, and if you rename a method, routing normally wouldn't be able to find that method. The solution is what you see in the example, which is to add the `ActionName("Delete")` attribute to the `DeleteConfirmed` method. That attribute performs mapping for the routing system so that a URL that includes `/Delete/` for a POST request will find the `DeleteConfirmed` method.

Another common work around for methods that have identical names and signatures is to artificially change the

signature of the POST method to include an extra (unused) parameter. That's what we did in a previous post when we added the `notUsed` parameter. You could do the same thing here for the `[HttpPost] Delete` method:

```
// POST: Movies/Delete/6
[ValidateAntiForgeryToken]
public async Task<IActionResult> Delete(int id, bool notUsed)
```

## Publish to Azure

See [Publish an ASP.NET Core web app to Azure App Service using Visual Studio](#) for instructions on how to publish this app to Azure using Visual Studio. The app can also be published from the [command line](#).

# Build web APIs with ASP.NET Core

7/11/2018 • 4 minutes to read • [Edit Online](#)

By [Scott Addie](#)

[View or download sample code](#) ([how to download](#))

This document explains how to build a web API in ASP.NET Core and when it's most appropriate to use each feature.

## Derive class from ControllerBase

Inherit from the [ControllerBase](#) class in a controller that's intended to serve as a web API. For example:

```
[Produces("application/json")]
[Route("api/[controller]")]
public class PetsController : ControllerBase
{
    private readonly PetsRepository _repository;

    public PetsController(PetsRepository repository)
    {
        _repository = repository;
    }

    [HttpGet]
    public async Task<ActionResult<List<Pet>>> GetAllAsync()
    {
        return await _repository.GetPetsAsync();
    }

    [HttpGet("{id}")]
    [ProducesResponseType(404)]
    public async Task<ActionResult<Pet>> GetByIdAsync(int id)
    {
        var pet = await _repository.GetPetAsync(id);

        if (pet == null)
        {
            return NotFound();
        }

        return pet;
    }

    [HttpPost]
    [ProducesResponseType(400)]
    public async Task<ActionResult<Pet>> CreateAsync(Pet pet)
    {
        if (!ModelState.IsValid)
        {
            return BadRequest(ModelState);
        }

        await _repository.AddPetAsync(pet);

        return CreatedAtAction(nameof(GetByIdAsync),
            new { id = pet.Id }, pet);
    }
}
```

```

[Produces("application/json")]
[Route("api/[controller]")]
public class PetsController : ControllerBase
{
    private readonly PetsRepository _repository;

    public PetsController(PetsRepository repository)
    {
        _repository = repository;
    }

    [HttpGet]
    [ProducesResponseType(typeof(IEnumerable<Pet>), 200)]
    public async Task<IActionResult> GetAllAsync()
    {
        var pets = await _repository.GetPetsAsync();

        return Ok(pets);
    }

    [HttpGet("{id}")]
    [ProducesResponseType(typeof(Pet), 200)]
    [ProducesResponseType(404)]
    public async Task<IActionResult> GetByIdAsync(int id)
    {
        var pet = await _repository.GetPetAsync(id);

        if (pet == null)
        {
            return NotFound();
        }

        return Ok(pet);
    }

    [HttpPost]
    [ProducesResponseType(typeof(Pet), 201)]
    [ProducesResponseType(400)]
    public async Task<IActionResult> CreateAsync([FromBody] Pet pet)
    {
        if (!ModelState.IsValid)
        {
            return BadRequest(ModelState);
        }

        await _repository.AddPetAsync(pet);

        return CreatedAtAction(nameof(GetByIdAsync),
            new { id = pet.Id }, pet);
    }
}

```

The  `ControllerBase` class provides access to several properties and methods. In the preceding code, examples include `BadRequest` and `CreatedAtAction`. These methods are called within action methods to return HTTP 400 and 201 status codes, respectively. The  `ModelState` property, also provided by  `ControllerBase`, is accessed to handle request model validation.

## Annotate class with ApiControllerAttribute

ASP.NET Core 2.1 introduces the `[ApiController]` attribute to denote a web API controller class. For example:

```
[Route("api/[controller]")]
[ApiController]
public class ProductsController : ControllerBase
```

A compatibility version of 2.1 or later, set via [SetCompatibilityVersion](#), is required to use this attribute. For example, the highlighted code in `Startup.ConfigureServices` sets the 2.1 compatibility flag:

```
services.AddMvc()
    .SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
```

The `[ApiController]` attribute is commonly coupled with `ControllerBase` to enable REST-specific behavior for controllers. `ControllerBase` provides access to methods such as [NotFound](#) and [File](#).

Another approach is to create a custom base controller class annotated with the `[ApiController]` attribute:

```
[ApiController]
public class MyBaseController
{}
```

The following sections describe convenience features added by the attribute.

### Automatic HTTP 400 responses

Validation errors automatically trigger an HTTP 400 response. The following code becomes unnecessary in your actions:

```
[ProducesResponseType(typeof(Pet), 201)]
[ProducesResponseType(400)]
public async Task<IActionResult> CreateAsync([FromBody] Pet pet)
```

The default behavior is disabled when the [SuppressModelStateInvalidFilter](#) property is set to `true`. Add the following code in `Startup.ConfigureServices` after

```
services.AddMvc().SetCompatibilityVersion(CompatibilityVersion.Version_2_1); :
```

```
services.Configure<ApiBehaviorOptions>(options =>
{
    options.SuppressConsumesConstraintForFormFileParameters = true;
    options.SuppressInferBindingSourcesForParameters = true;
    options.SuppressModelStateInvalidFilter = true;
});
```

### Binding source parameter inference

A binding source attribute defines the location at which an action parameter's value is found. The following binding source attributes exist:

ATTRIBUTE	BINDING SOURCE
<a href="#">[FromBody]</a>	Request body
<a href="#">[FromForm]</a>	Form data in the request body
<a href="#">[FromHeader]</a>	Request header

ATTRIBUTE	BINDING SOURCE
[FromQuery]	Request query string parameter
[FromRoute]	Route data from the current request
[FromServices]	The request service injected as an action parameter

## **WARNING**

Don't use `[FromRoute]` when values might contain `%2f` (that is `/`). `%2f` won't be unescaped to `/`. Use `[FromQuery]` if the value might contain `%2f`.

Without the `[ApiController]` attribute, binding source attributes are explicitly defined. In the following example, the `[FromQuery]` attribute indicates that the `discontinuedOnly` parameter value is provided in the request URL's query string:

```
[HttpGet]
public async Task<ActionResult<List<Product>>> GetAsync(
    [FromQuery] bool discontinuedOnly = false)
{
    List<Product> products = null;

    if (discontinuedOnly)
    {
        products = await _repository.GetDiscontinuedProductsAsync();
    }
    else
    {
        products = await _repository.GetProductsAsync();
    }

    return products;
}
```

Inference rules are applied for the default data sources of action parameters. These rules configure the binding sources you're otherwise likely to manually apply to the action parameters. The binding source attributes behave as follows:

- **[FromBody]** is inferred for complex type parameters. An exception to this rule is any complex, built-in type with a special meaning, such as `IFormCollection` and `CancellationToken`. The binding source inference code ignores those special types. When an action has more than one parameter explicitly specified (via `[FromBody]`) or inferred as bound from the request body, an exception is thrown. For example, the following action signatures cause an exception:

- **[FromForm]** is inferred for action parameters of type [IFormFile](#) and [IFormFileCollection](#). It's not inferred for any simple or user-defined types.
- **[FromRoute]** is inferred for any action parameter name matching a parameter in the route template. When more than one route matches an action parameter, any route value is considered **[FromRoute]**.
- **[FromQuery]** is inferred for any other action parameters.

The default inference rules are disabled when the [SuppressInferBindingSourcesForParameters](#) property is set to `true`. Add the following code in `Startup.ConfigureServices` after

```
services.AddMvc().SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
```

```
services.Configure<ApiBehaviorOptions>(options =>
{
    options.SuppressConsumesConstraintForFormFileParameters = true;
    options.SuppressInferBindingSourcesForParameters = true;
    options.SuppressModelStateInvalidFilter = true;
});
```

## Multipart/form-data request inference

When an action parameter is annotated with the **[FromForm]** attribute, the `multipart/form-data` request content type is inferred.

The default behavior is disabled when the [SuppressConsumesConstraintForFormFileParameters](#) property is set to `true`. Add the following code in `Startup.ConfigureServices` after

```
services.AddMvc().SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
```

```
services.Configure<ApiBehaviorOptions>(options =>
{
    options.SuppressConsumesConstraintForFormFileParameters = true;
    options.SuppressInferBindingSourcesForParameters = true;
    options.SuppressModelStateInvalidFilter = true;
});
```

## Attribute routing requirement

Attribute routing becomes a requirement. For example:

```
[Route("api/[controller]")]
[ApiController]
public class ProductsController : ControllerBase
```

Actions are inaccessible via [conventional routes](#) defined in [UseMvc](#) or by [UseMvcWithDefaultRoute](#) in `Startup.Configure`.

# Create a Web API with ASP.NET Core and Visual Studio Code

6/21/2018 • 15 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Mike Wasson](#)

In this tutorial, build a web API for managing a list of "to-do" items. A UI isn't constructed.

There are three versions of this tutorial:

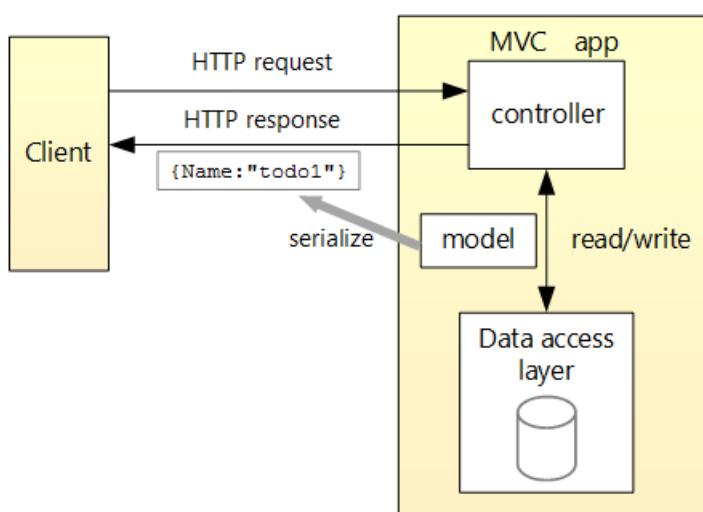

- macOS, Linux, Windows: Web API with Visual Studio Code (This tutorial)
- macOS: [Web API with Visual Studio for Mac](#)
- Windows: [Web API with Visual Studio for Windows](#)

## Overview

This tutorial creates the following API:

API	DESCRIPTION	REQUEST BODY	RESPONSE BODY
GET /api/todo	Get all to-do items	None	Array of to-do items
GET /api/todo/{id}	Get an item by ID	None	To-do item
POST /api/todo	Add a new item	To-do item	To-do item
PUT /api/todo/{id}	Update an existing item	To-do item	None
DELETE /api/todo/{id}	Delete an item	None	None

The following diagram shows the basic design of the app.

- The client is whatever consumes the web API (mobile app, browser, etc.). This tutorial doesn't create a client. [Postman](#) or [curl](#) is used as the client to test the app.
- A *model* is an object that represents the data in the app. In this case, the only model is a to-do item. Models are represented as C# classes, also known as **Plain Old CLR Object** (POCOs).

- A *controller* is an object that handles HTTP requests and creates the HTTP response. This app has a single controller.
- To keep the tutorial simple, the app doesn't use a persistent database. The sample app stores to-do items in an in-memory database.

## Prerequisites

Install the following:

- .NET Core SDK 2.0 or later
- Visual Studio Code
- C# for Visual Studio Code
- .NET Core 2.1 SDK or later
- Visual Studio Code
- C# for Visual Studio Code

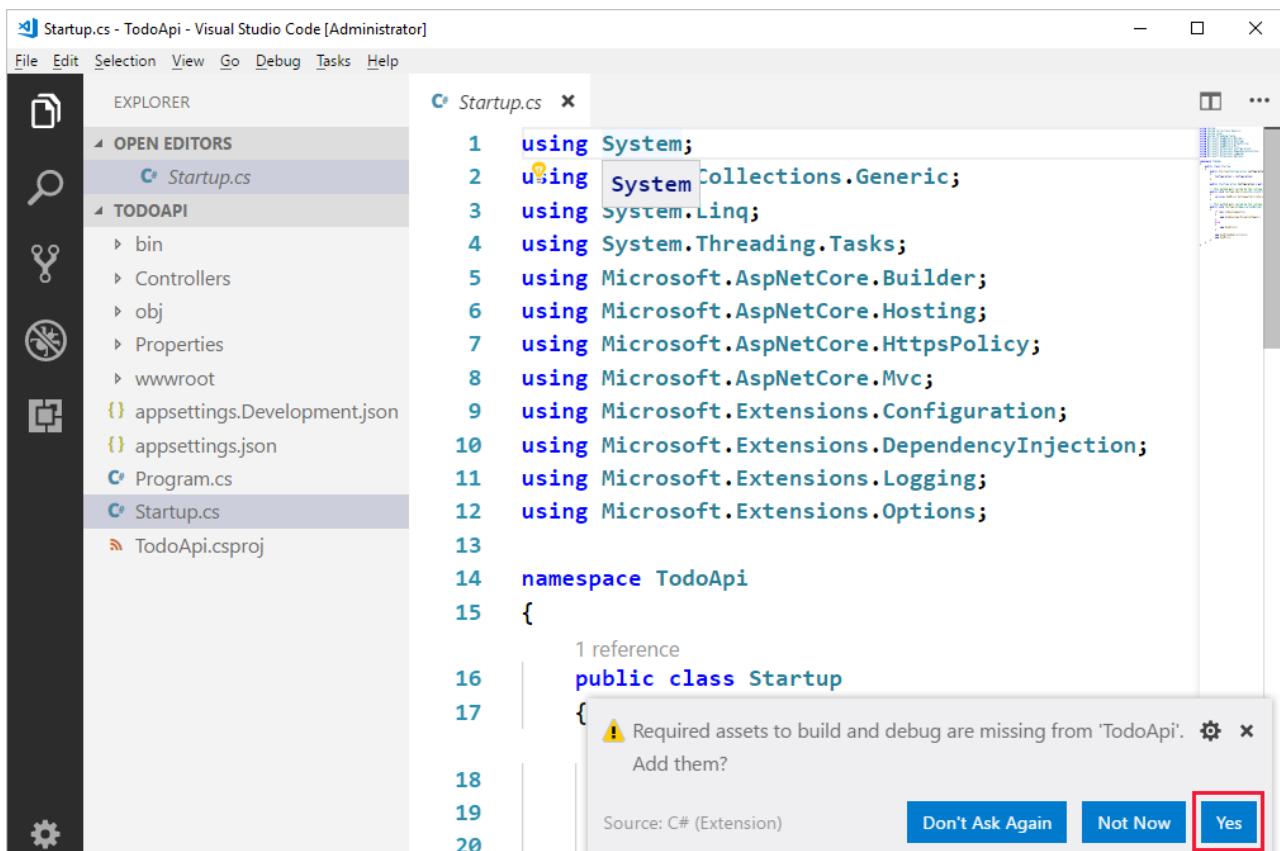

## Create the project

From a console, run the following commands:

```
dotnet new webapi -o TodoApi
code TodoApi
```

The *TodoApi* folder opens in Visual Studio Code (VS Code). Select the *Startup.cs* file.

- Select **Yes** to the **Warn** message "Required assets to build and debug are missing from 'TodoApi'. Add them?"
- Select **Restore** to the **Info** message "There are unresolved dependencies".

Press **Debug** (F5) to build and run the program. In a browser, navigate to <http://localhost:5000/api/values>. The

following output is displayed:

```
["value1","value2"]
```

See [Visual Studio Code help](#) for tips on using VS Code.

## Add support for Entity Framework Core

Creating a new project in ASP.NET Core 2.0 adds the [Microsoft.AspNetCore.All](#) package reference to the `TodoApi.csproj` file:

```
<ItemGroup>
  <PackageReference Include="Microsoft.AspNetCore.All" Version="2.0.3" />
</ItemGroup>
```

Creating a new project in ASP.NET Core 2.1 or later adds the [Microsoft.AspNetCore.App](#) package reference to the `TodoApi.csproj` file:

```
<ItemGroup>
  <PackageReference Include="Microsoft.AspNetCore.App" Version="2.1.1" />
</ItemGroup>
```

There's no need to install the [Entity Framework Core InMemory](#) database provider separately. This database provider allows Entity Framework Core to be used with an in-memory database.

## Add a model class

A model is an object representing the data in your app. In this case, the only model is a to-do item.

Add a folder named `Models`. You can put model classes anywhere in your project, but the `Models` folder is used by convention.

Add a `TodoItem` class with the following code:

```
namespace TodoApi.Models
{
    public class TodoItem
    {
        public long Id { get; set; }
        public string Name { get; set; }
        public bool IsComplete { get; set; }
    }
}
```

The database generates the `Id` when a `TodoItem` is created.

## Create the database context

The *database context* is the main class that coordinates Entity Framework functionality for a given data model. You create this class by deriving from the [Microsoft.EntityFrameworkCore.DbContext](#) class.

Add a `TodoContext` class in the `Models` folder:

```
using Microsoft.EntityFrameworkCore;

namespace TodoApi.Models
{
    public class TodoContext : DbContext
    {
        public TodoContext(DbContextOptions<TodoContext> options)
            : base(options)
        {
        }

        public DbSet<TodoItem> TodoItems { get; set; }
    }
}
```

## Register the database context

In this step, the database context is registered with the [dependency injection](#) container. Services (such as the DB context) that are registered with the dependency injection (DI) container are available to the controllers.

Register the DB context with the service container using the built-in support for [dependency injection](#). Replace the contents of the *Startup.cs* file with the following code:

```
using Microsoft.AspNetCore.Builder;
using Microsoft.AspNetCore.Mvc;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using TodoApi.Models;

namespace TodoApi
{
    public class Startup
    {
        public void ConfigureServices(IServiceCollection services)
        {
            services.AddDbContext<TodoContext>(opt =>
                opt.UseInMemoryDatabase("TodoList"));
            services.AddMvc()
                .SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
        }

        public void Configure(IApplicationBuilder app)
        {
            app.UseMvc();
        }
    }
}
```

```

using Microsoft.AspNetCore.Builder;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using TodoApi.Models;

namespace TodoApi
{
    public class Startup
    {
        public void ConfigureServices(IServiceCollection services)
        {
            services.AddDbContext<TodoContext>(opt =>
                opt.UseInMemoryDatabase("TodoList"));
            services.AddMvc();
        }

        public void Configure(IApplicationBuilder app)
        {
            app.UseMvc();
        }
    }
}

```

The preceding code:

- Removes the unused code.
- Specifies an in-memory database is injected into the service container.

## Add a controller

In the *Controllers* folder, create a class named `TodoController`. Replace its contents with the following code:

```

using Microsoft.AspNetCore.Mvc;
using System.Collections.Generic;
using System.Linq;
using TodoApi.Models;

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

        public TodoController(TodoContext context)
        {
            _context = context;

            if (_context.TodoItems.Count() == 0)
            {
                _context.TodoItems.Add(new TodoItem { Name = "Item1" });
                _context.SaveChanges();
            }
        }
    }
}

```

The preceding code defines an API controller class without methods. In the next sections, methods are added to implement the API.

```

using Microsoft.AspNetCore.Mvc;
using System.Collections.Generic;
using System.Linq;
using TodoApi.Models;

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    [ApiController]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

        public TodoController(TodoContext context)
        {
            _context = context;

            if (_context.TodoItems.Count() == 0)
            {
                _context.TodoItems.Add(new TodoItem { Name = "Item1" });
                _context.SaveChanges();
            }
        }
    }
}

```

The preceding code defines an API controller class without methods. In the next sections, methods are added to implement the API. The class is annotated with an `[ApiController]` attribute to enable some convenient features. For information on features enabled by the attribute, see [Annotate class with ApiControllerAttribute](#).

The controller's constructor uses [Dependency Injection](#) to inject the database context (`TodoContext`) into the controller. The database context is used in each of the [CRUD](#) methods in the controller. The constructor adds an item to the in-memory database if one doesn't exist.

## Get to-do items

To get to-do items, add the following methods to the `TodoController` class:

```

[HttpGet]
public List<TodoItem> GetAll()
{
    return _context.TodoItems.ToList();
}

[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}

```

```

[HttpGet]
public ActionResult<List<TodoItem>> GetAll()
{
    return _context.TodoItems.ToList();
}

[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}

```

These methods implement the two GET methods:

- `GET /api/todo`
- `GET /api/todo/{id}`

Here's a sample HTTP response for the `GetAll` method:

```
[
{
    "id": 1,
    "name": "Item1",
    "isComplete": false
}
]
```

Later in the tutorial, I'll show how the HTTP response can be viewed with [Postman](#) or [curl](#).

## Routing and URL paths

The `[HttpGet]` attribute denotes a method that responds to an HTTP GET request. The URL path for each method is constructed as follows:

- Take the template string in the controller's `Route` attribute:

```

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;
    }
}
```

```

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    [ApiController]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;
    }
}
```

- Replace `[controller]` with the name of the controller, which is the controller class name minus the "Controller" suffix. For this sample, the controller class name is **TodoController** and the root name is "todo". ASP.NET Core [routing](#) is case insensitive.

- If the `[HttpGet]` attribute has a route template (such as `[HttpGet("/products")]`), append that to the path. This sample doesn't use a template. For more information, see [Attribute routing with Http\[Verb\] attributes](#).

In the following  `GetById` method, `"{id}"` is a placeholder variable for the unique identifier of the to-do item. When  `GetById` is invoked, it assigns the value of `"{id}"` in the URL to the method's `id` parameter.

```
[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}
```

```
[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}
```

`Name = "GetTodo"` creates a named route. Named routes:

- Enable the app to create an HTTP link using the route name.
- Are explained later in the tutorial.

## Return values

The  `GetAll` method returns a collection of  `TodoItem` objects. MVC automatically serializes the object to  `JSON` and writes the JSON into the body of the response message. The response code for this method is 200, assuming there are no unhandled exceptions. Unhandled exceptions are translated into 5xx errors.

In contrast, the  `GetById` method returns the more general `IActionResult type`, which represents a wide range of return types.  `GetById` has two different return types:

- If no item matches the requested ID, the method returns a 404 error. Returning `NotFound` returns an HTTP 404 response.
- Otherwise, the method returns 200 with a JSON response body. Returning `Ok` results in an HTTP 200 response.

In contrast, the  `GetById` method returns the `ActionResult<T> type`, which represents a wide range of return types.  `GetById` has two different return types:

- If no item matches the requested ID, the method returns a 404 error. Returning `NotFound` returns an HTTP 404 response.
- Otherwise, the method returns 200 with a JSON response body. Returning  `item` results in an HTTP 200 response.

## Launch the app

In VS Code, press F5 to launch the app. Navigate to <http://localhost:5000/api/todo> (the  `Todo` controller we created).

## Call the Web API with jQuery

In this section, an HTML page is added that uses jQuery to call the Web API. jQuery initiates the request and updates the page with the details from the API's response.

Configure the project to serve static files and to enable default file mapping. This is accomplished by invoking the [UseStaticFiles](#) and [UseDefaultFiles](#) extension methods in *Startup.Configure*. For more information, see [Static files](#).

```
public void Configure(IApplicationBuilder app)
{
    app.UseDefaultFiles();
    app.UseStaticFiles();
    app.UseMvc();
}
```

Add an HTML file, named *index.html*, to the project's *wwwroot* directory. Replace its contents with the following markup:

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="UTF-8">
    <title>To-do CRUD</title>
    <style>
        input[type='submit'], button, [aria-label] {
            cursor: pointer;
        }

        #spoiler {
            display: none;
        }

        table {
            font-family: Arial, sans-serif;
            border: 1px solid;
            border-collapse: collapse;
        }

        th {
            background-color: #0066CC;
            color: white;
        }

        td {
            border: 1px solid;
            padding: 5px;
        }
    </style>
</head>
<body>
    <h1>To-do CRUD</h1>
    <h3>Add</h3>
    <form action="javascript:void(0);" method="POST" onsubmit="addItem()">
        <input type="text" id="add-name" placeholder="New to-do">
        <input type="submit" value="Add">
    </form>

    <div id="spoiler">
        <h3>Edit</h3>
        <form class="my-form">
            <input type="hidden" id="edit-id">
            <input type="checkbox" id="edit-isComplete">
            <input type="text" id="edit-name">
            <input type="submit" value="Edit">
        </form>
    </div>
</body>
```

```

        \a UNQUOTE- CLOSEINPUT()  DATA-TABSTOP- CLOSE /DATA0000,\a/
    </form>
</div>

<p id="counter"></p>

<table>
    <tr>
        <th>Is Complete</th>
        <th>Name</th>
        <th></th>
        <th></th>
    </tr>
    <tbody id="todos"></tbody>
</table>

<script src="https://code.jquery.com/jquery-3.3.1.min.js"
        integrity="sha256-FgpCb/KJQ1LNfOu91ta32o/NMZxltwRo8QtmkMRdAu8="
        crossorigin="anonymous"></script>
<script src="site.js"></script>
</body>
</html>

```

Add a JavaScript file, named *site.js*, to the project's *wwwroot* directory. Replace its contents with the following code:

```

const uri = 'api/todo';
let todos = null;
function getCount(data) {
    const el = $('#counter');
    let name = 'to-do';
    if (data) {
        if (data > 1) {
            name = 'to-dos';
        }
        el.text(data + ' ' + name);
    } else {
        el.html('No ' + name);
    }
}

$(document).ready(function () {
    getData();
});

function getData() {
    $.ajax({
        type: 'GET',
        url: uri,
        success: function (data) {
            $('#todos').empty();
            getCount(data.length);
            $.each(data, function (key, item) {
                const checked = item.isComplete ? 'checked' : '';

                $('<tr><td><input disabled="true" type="checkbox" ' + checked + '></td>' +
                    '<td>' + item.name + '</td>' +
                    '<td><button onclick="editItem(' + item.id + ')>Edit</button></td>' +
                    '<td><button onclick="deleteItem(' + item.id + ')>Delete</button></td>' +
                    '</tr>').appendTo($('#todos'));
            });
            todos = data;
        }
    });
}

function addItem() {
    const item = f

```

```

const item = {
  'name': $('#add-name').val(),
  'isComplete': false
};

$.ajax({
  type: 'POST',
  accepts: 'application/json',
  url: uri,
  contentType: 'application/json',
  data: JSON.stringify(item),
  error: function (jqXHR, textStatus, errorThrown) {
    alert('here');
  },
  success: function (result) {
    getData();
    $('#add-name').val('');
  }
});

function deleteItem(id) {
  $.ajax({
    url: uri + '/' + id,
    type: 'DELETE',
    success: function (result) {
      getData();
    }
  });
}

function editItem(id) {
  $.each(todos, function (key, item) {
    if (item.id === id) {
      $('#edit-name').val(item.name);
      $('#edit-id').val(item.id);
      $('#edit-isComplete').val(item.isComplete);
    }
  });
  $('#spoiler').css({ 'display': 'block' });
}

$('.my-form').on('submit', function () {
  const item = {
    'name': $('#edit-name').val(),
    'isComplete': $('#edit-isComplete').is(':checked'),
    'id': $('#edit-id').val()
  };

  $.ajax({
    url: uri + '/' + $('#edit-id').val(),
    type: 'PUT',
    accepts: 'application/json',
    contentType: 'application/json',
    data: JSON.stringify(item),
    success: function (result) {
      getData();
    }
  });

  closeInput();
  return false;
});

function closeInput() {
  $('#spoiler').css({ 'display': 'none' });
}

```

A change to the ASP.NET Core project's launch settings may be required to test the HTML page locally. Open `launchSettings.json` in the `Properties` directory of the project. Remove the `launchUrl` property to force the app to open at `index.html`—the project's default file.

There are several ways to get jQuery. In the preceding snippet, the library is loaded from a CDN. This sample is a complete CRUD example of calling the API with jQuery. There are additional features in this sample to make the experience richer. Below are explanations around the calls to the API.

## Get a list of to-do items

To get a list of to-do items, send an HTTP GET request to `/api/todo`.

The jQuery `ajax` function sends an AJAX request to the API, which returns JSON representing an object or array. This function can handle all forms of HTTP interaction, sending an HTTP request to the specified `url`. `GET` is used as the `type`. The `success` callback function is invoked if the request succeeds. In the callback, the DOM is updated with the to-do information.

```
$(document).ready(function () {
    getData();
});

function getData() {
    $.ajax({
        type: 'GET',
        url: uri,
        success: function (data) {
            $('#todos').empty();
            getCount(data.length);
            $.each(data, function (key, item) {
                const checked = item.isComplete ? 'checked' : '';

                $('<tr><td><input disabled="true" type="checkbox" ' + checked + '></td>' +
                    '<td>' + item.name + '</td>' +
                    '<td><button onclick="editItem(' + item.id + ')>Edit</button></td>' +
                    '<td><button onclick="deleteItem(' + item.id + ')>Delete</button></td>' +
                    '</tr>').appendTo($('#todos'));
            });
            todos = data;
        }
    });
}
```

## Add a to-do item

To add a to-do item, send an HTTP POST request to `/api/todo/`. The request body should contain a to-do object. The `ajax` function is using `POST` to call the API. For `POST` and `PUT` requests, the request body represents the data sent to the API. The API is expecting a JSON request body. The `accepts` and `contentType` options are set to `application/json` to classify the media type being received and sent, respectively. The data is converted to a JSON object using `JSON.stringify`. When the API returns a successful status code, the `getData` function is invoked to update the HTML table.

```

function addItem() {
  const item = {
    'name': $('#add-name').val(),
    'isComplete': false
  };

  $.ajax({
    type: 'POST',
    accepts: 'application/json',
    url: uri,
    contentType: 'application/json',
    data: JSON.stringify(item),
    error: function (jqXHR, textStatus, errorThrown) {
      alert('here');
    },
    success: function (result) {
      getData();
      $('#add-name').val('');
    }
  });
}

```

## Update a to-do item

Updating a to-do item is very similar to adding one, since both rely on a request body. The only real difference between the two in this case is that the `url` changes to add the unique identifier of the item, and the `type` is `PUT`.

```

$.ajax({
  url: uri + '/' + $('#edit-id').val(),
  type: 'PUT',
  accepts: 'application/json',
  contentType: 'application/json',
  data: JSON.stringify(item),
  success: function (result) {
    getData();
  }
});

```

## Delete a to-do item

Deleting a to-do item is accomplished by setting the `type` on the AJAX call to `DELETE` and specifying the item's unique identifier in the URL.

```

$.ajax({
  url: uri + '/' + id,
  type: 'DELETE',
  success: function (result) {
    getData();
  }
});

```

## Implement the other CRUD operations

In the following sections, `Create`, `Update`, and `Delete` methods are added to the controller.

### Create

Add the following `Create` method:

```

[HttpPost]
public IActionResult Create([FromBody] TodoItem item)
{
    if (item == null)
    {
        return BadRequest();
    }

    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}

```

The preceding code is an HTTP POST method, as indicated by the `[HttpPost]` attribute. The `[FromBody]` attribute tells MVC to get the value of the to-do item from the body of the HTTP request.

```

[HttpPost]
public IActionResult Create(TodoItem item)
{
    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}

```

The preceding code is an HTTP POST method, as indicated by the `[HttpPost]` attribute. MVC gets the value of the to-do item from the body of the HTTP request.

The `CreatedAtRoute` method:

- Returns a 201 response. HTTP 201 is the standard response for an HTTP POST method that creates a new resource on the server.
- Adds a Location header to the response. The Location header specifies the URI of the newly created to-do item. See [10.2.2 201 Created](#).
- Uses the "GetTodo" named route to create the URL. The "GetTodo" named route is defined in  `GetById`:

```

[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}

```

```

[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}

```

## Use Postman to send a Create request

- Start the app.
- Open Postman.

The screenshot shows the Postman interface with a red box highlighting the 'POST' method in the top bar. Another red box highlights the 'Body' tab in the navigation bar. A third red box highlights the 'raw' radio button under the body type dropdown. A fourth red box highlights the JSON (application/json) option in the dropdown. The request URL is https://localhost:44375/api/todo. The response pane shows a status of 201 Created and the JSON response: { "id": 6, "name": "walk dog", "isComplete": true }.

- Update the port number in the localhost URL.
- Set the HTTP method to *POST*.
- Click the **Body** tab.
- Select the **raw** radio button.
- Set the type to *JSON (application/json)*.
- Enter a request body with a to-do item resembling the following JSON:

```
{  
  "name": "walk dog",  
  "isComplete": true  
}
```

- Click the **Send** button.

### TIP

If no response displays after clicking **Send**, disable the **SSL certification verification** option. This is found under **File > Settings**. Click the **Send** button again after disabling the setting.

Click the **Headers** tab in the **Response** pane and copy the **Location** header value:

The screenshot shows the Postman application interface. At the top, there's a navigation bar with File, Edit, View, Help, and a workspace dropdown labeled "My Workspace". Below the header are buttons for New, Import, Runner, and a plus sign. To the right of the workspace are icons for sync status ("IN SYNC") and notifications.

The main area shows a request configuration for a POST method to the URL <https://localhost:44375/api/todo>. The "Body" tab is selected, showing a JSON payload:

```
1 [{}  
2   "name": "walk dog",  
3   "isComplete": true  
4 }]
```

Below the body, the "Headers" tab is highlighted with a red box, showing seven headers: Content-Type → application/json; charset=utf-8, Date → Fri, 27 Apr 2018 18:32:32 GMT, and Location → <https://localhost/api/Todo/6>.

The status bar at the bottom indicates a 201 Created response and a time of 148 ms.

The Location header URI can be used to access the new item.

## Update

Add the following `Update` method:

```
[HttpPut("{id}")]  
public IActionResult Update(long id, [FromBody] TodoItem item)  
{  
    if (item == null || item.Id != id)  
    {  
        return BadRequest();  
    }  
  
    var todo = _context.TodoItems.Find(id);  
    if (todo == null)  
    {  
        return NotFound();  
    }  
  
    todo.IsComplete = item.IsComplete;  
    todo.Name = item.Name;  
  
    _context.TodoItems.Update(todo);  
    _context.SaveChanges();  
    return NoContent();  
}
```

```
[HttpPut("{id}")]
public IActionResult Update(long id, TodoItem item)
{
    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    todo.IsComplete = item.IsComplete;
    todo.Name = item.Name;

    _context.TodoItems.Update(todo);
    _context.SaveChanges();
    return NoContent();
}
```

`Update` is similar to `Create`, except it uses HTTP PUT. The response is [204 \(No Content\)](#). According to the HTTP specification, a PUT request requires the client to send the entire updated entity, not just the deltas. To support partial updates, use HTTP PATCH.

Use Postman to update the to-do item's name to "walk cat":

The screenshot shows the Postman application interface. The request URL is `https://localhost:44375/api/todo/1`. The method is set to `PUT`. The `Body` tab is selected, and the `raw` option is chosen. The JSON payload is:

```
1 {  
2     "name": "walk cat",  
3     "isComplete": true  
4 }
```

The response status is `204 No Content` and the time taken is `70 ms`.

## Delete

Add the following `Delete` method:

```
[HttpDelete("{id}")]
public IActionResult Delete(long id)
{
    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    _context.TodoItems.Remove(todo);
    _context.SaveChanges();
    return NoContent();
}
```

The `Delete` response is [204 \(No Content\)](#).

Use Postman to delete the to-do item:

The screenshot shows the Postman application window. The top navigation bar includes File, Edit, View, Help, New, Import, Runner, My Workspace (with three environments listed), and various status indicators like IN SYNC and notifications.

The main interface shows a request configuration for a DELETE method directed at <https://localhost:44375/api/todo/1>. The 'Authorization' tab is selected, showing 'No Auth' selected from a dropdown. A note states: "The authorization header will be automatically generated when you send the request. [Learn more about authorization](#)". The 'Headers' tab shows four headers: 'Content-Type: application/json', 'Accept: application/json', 'Cache-Control: no-cache', and 'Postman-Token: 1234567890'. The 'Body' tab is currently active, showing a JSON object with a single key '1':

```
{
  "1": {}
}
```

The bottom status bar indicates the request was successful with a status of 204 No Content and a time of 735 ms.

- [Controller action return types](#)
- For information about deploying an API, including to Azure App Service, see [Host and deploy](#).
- [View or download sample code](#). See [how to download](#).

# Create a Web API with ASP.NET Core and Visual Studio for Mac

6/21/2018 • 15 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Mike Wasson](#)

In this tutorial, build a web API for managing a list of "to-do" items. The UI isn't constructed.

There are three versions of this tutorial:

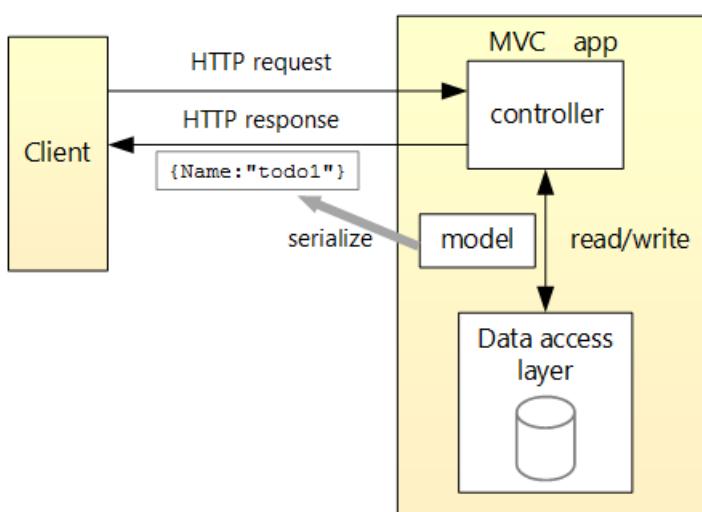

- macOS: Web API with Visual Studio for Mac (This tutorial)
- Windows: [Web API with Visual Studio for Windows](#)
- macOS, Linux, Windows: [Web API with Visual Studio Code](#)

## Overview

This tutorial creates the following API:

API	DESCRIPTION	REQUEST BODY	RESPONSE BODY
GET /api/todo	Get all to-do items	None	Array of to-do items
GET /api/todo/{id}	Get an item by ID	None	To-do item
POST /api/todo	Add a new item	To-do item	To-do item
PUT /api/todo/{id}	Update an existing item	To-do item	None
DELETE /api/todo/{id}	Delete an item	None	None

The following diagram shows the basic design of the app.

- The client is whatever consumes the web API (mobile app, browser, etc.). This tutorial doesn't create a client. [Postman](#) or [curl](#) is used as the client to test the app.
- A *model* is an object that represents the data in the app. In this case, the only model is a to-do item. Models are represented as C# classes, also known as **Plain Old ClR Object** (POCOs).

- A *controller* is an object that handles HTTP requests and creates the HTTP response. This app has a single controller.
- To keep the tutorial simple, the app doesn't use a persistent database. The sample app stores to-do items in an in-memory database.

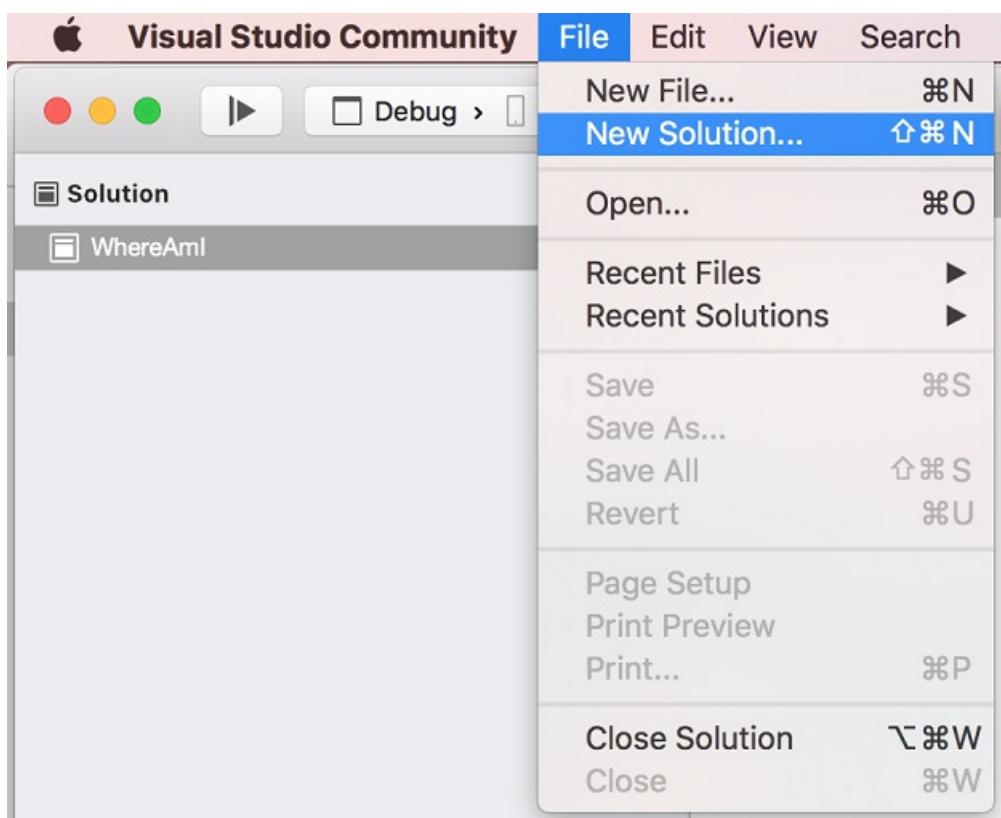

See [Introduction to ASP.NET Core MVC on macOS or Linux](#) for an example that uses a persistent database.

## Prerequisites

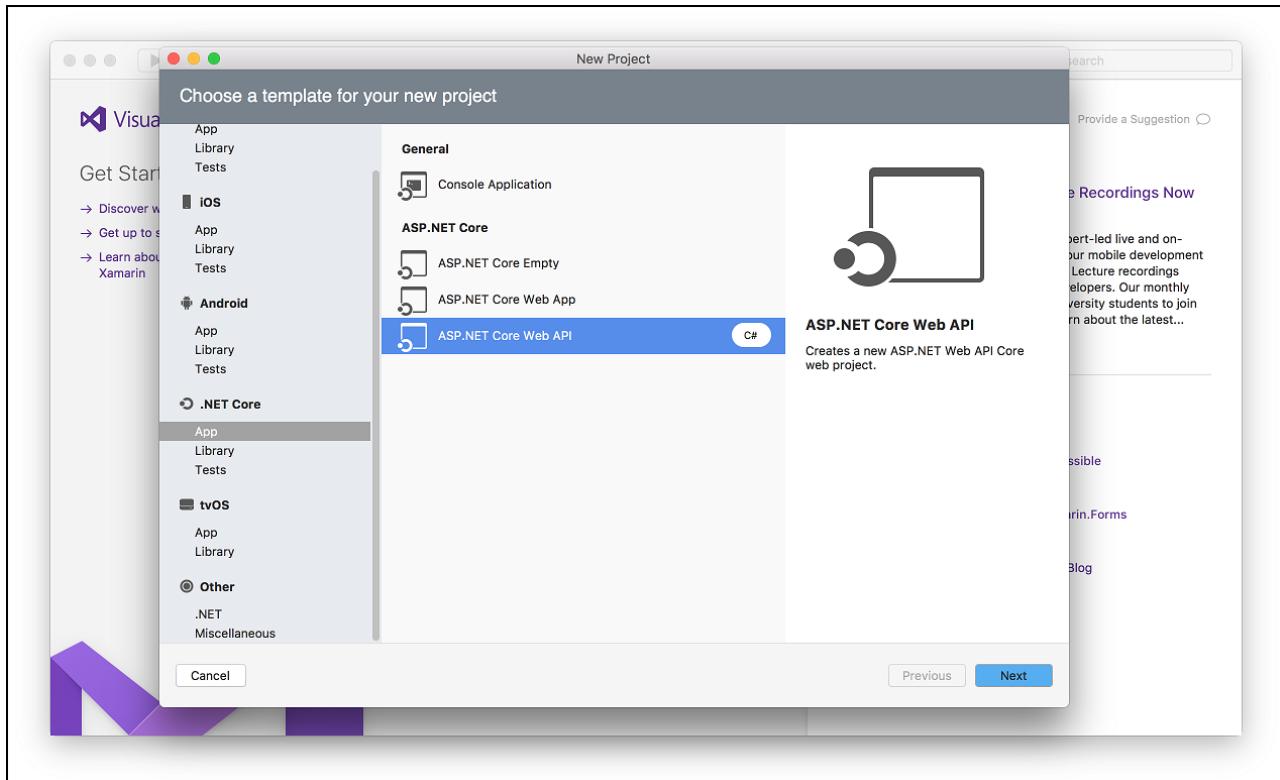

[Visual Studio for Mac](#)

## Create the project

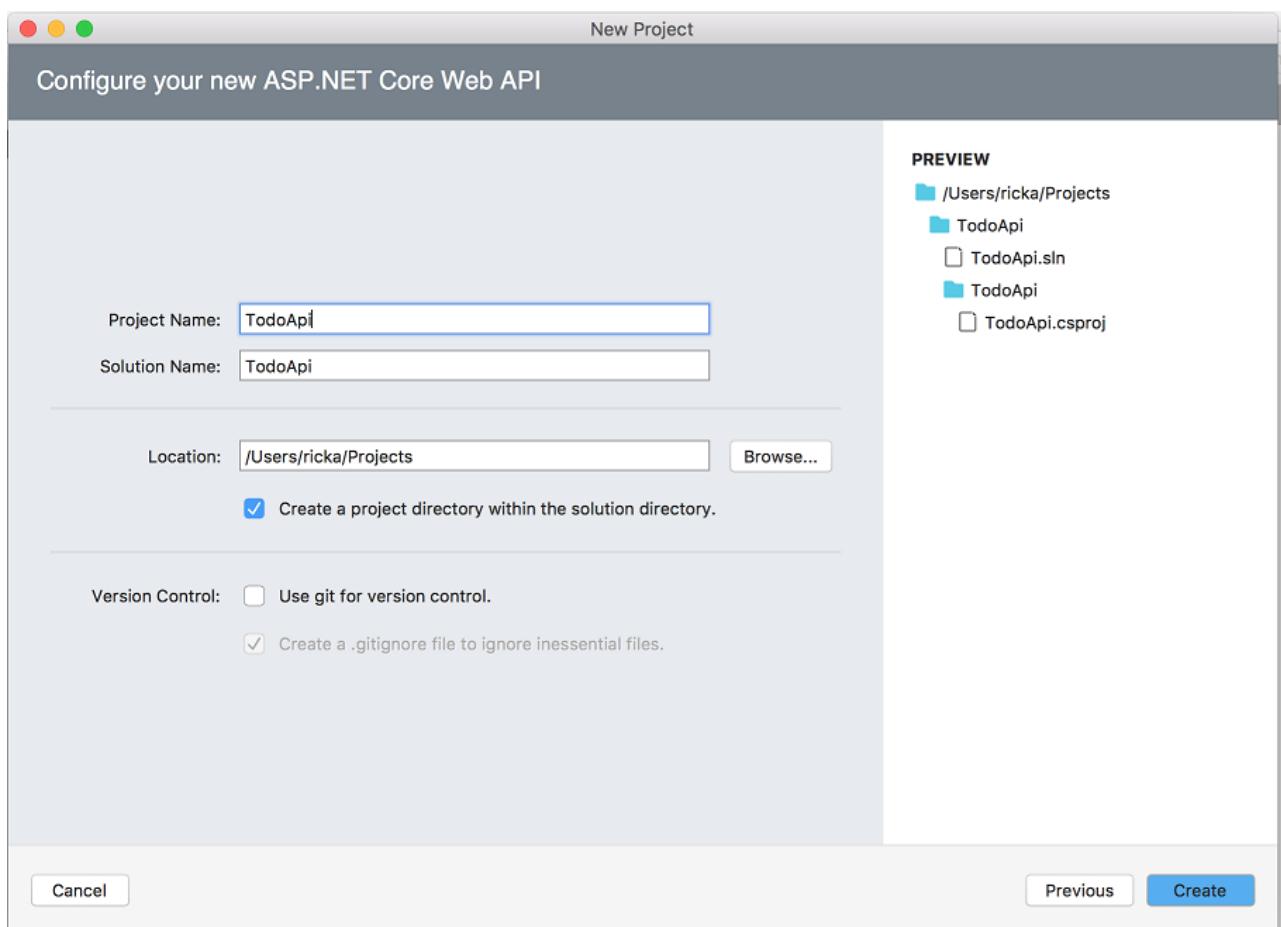

From Visual Studio, select **File > New Solution**.

Select **.NET Core App > ASP.NET Core Web API > Next**.

Enter *TodoApi* for the **Project Name**, and then click **Create**.

## Launch the app

In Visual Studio, select **Run > Start With Debugging** to launch the app. Visual Studio launches a browser and navigates to `http://localhost:5000`. You get an HTTP 404 (Not Found) error. Change the URL to `http://localhost:<port>/api/values`. The `ValuesController` data is displayed:

```
["value1","value2"]
```

## Add support for Entity Framework Core

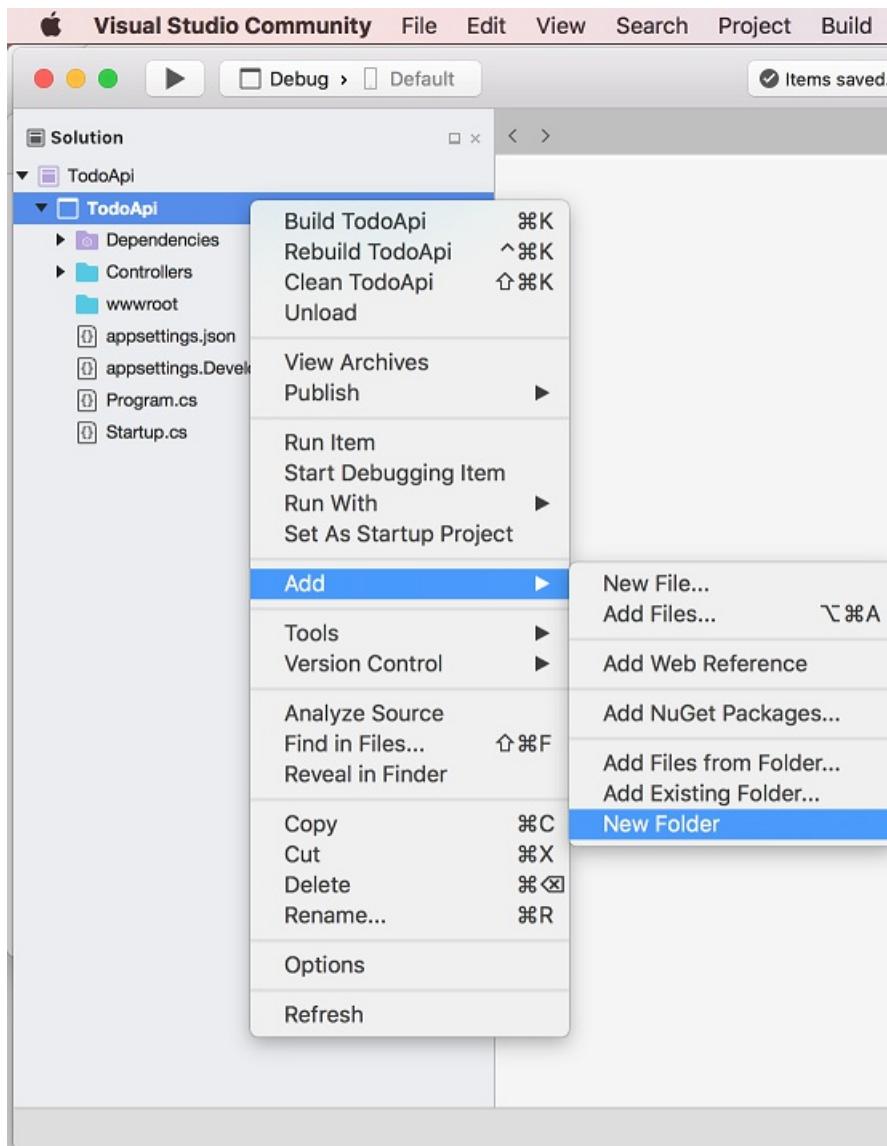

Install the [Entity Framework Core InMemory](#) database provider. This database provider allows Entity Framework Core to be used with an in-memory database.

- From the **Project** menu, select **Add NuGet Packages**.
  - Alternatively, you can right-click **Dependencies**, and then select **Add Packages**.
- Enter `EntityFrameworkCore.InMemory` in the search box.
- Select `Microsoft.EntityFrameworkCore.InMemory`, and then select **Add Package**.

## Add a model class

A model is an object representing the data in your app. In this case, the only model is a to-do item.

In Solution Explorer, right-click the project. Select **Add > New Folder**. Name the folder *Models*.

### NOTE

You can put model classes anywhere in your project, but the *Models* folder is used by convention.

Right-click the *Models* folder, and select **Add > New File > General > Empty Class**. Name the class *TodoItem*,

and then click **New**.

Replace the generated code with:

```
namespace TodoApi.Models
{
    public class TodoItem
    {
        public long Id { get; set; }
        public string Name { get; set; }
        public bool IsComplete { get; set; }
    }
}
```

The database generates the `Id` when a `TodoItem` is created.

### Create the database context

The *database context* is the main class that coordinates Entity Framework functionality for a given data model. You create this class by deriving from the `Microsoft.EntityFrameworkCore.DbContext` class.

Add a `TodoContext` class to the *Models* folder.

```
using Microsoft.EntityFrameworkCore;

namespace TodoApi.Models
{
    public class TodoContext : DbContext
    {
        public TodoContext(DbContextOptions<TodoContext> options)
            : base(options)
        {

        }

        public DbSet<TodoItem> TodoItems { get; set; }
    }
}
```

### Register the database context

In this step, the database context is registered with the [dependency injection](#) container. Services (such as the DB context) that are registered with the dependency injection (DI) container are available to the controllers.

Register the DB context with the service container using the built-in support for [dependency injection](#). Replace the contents of the *Startup.cs* file with the following code:

```

using Microsoft.AspNetCore.Builder;
using Microsoft.AspNetCore.Mvc;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using TodoApi.Models;

namespace TodoApi
{
    public class Startup
    {
        public void ConfigureServices(IServiceCollection services)
        {
            services.AddDbContext<TodoContext>(opt =>
                opt.UseInMemoryDatabase("TodoList"));
            services.AddMvc()
                .SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
        }

        public void Configure(IApplicationBuilder app)
        {
            app.UseMvc();
        }
    }
}

```

```

using Microsoft.AspNetCore.Builder;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using TodoApi.Models;

namespace TodoApi
{
    public class Startup
    {
        public void ConfigureServices(IServiceCollection services)
        {
            services.AddDbContext<TodoContext>(opt =>
                opt.UseInMemoryDatabase("TodoList"));
            services.AddMvc();
        }

        public void Configure(IApplicationBuilder app)
        {
            app.UseMvc();
        }
    }
}

```

The preceding code:

- Removes the unused code.
- Specifies an in-memory database is injected into the service container.

## Add a controller

In Solution Explorer, in the *Controllers* folder, add the class `TodoController`.

Replace the generated code with the following:

```

using Microsoft.AspNetCore.Mvc;
using System.Collections.Generic;
using System.Linq;
using TodoApi.Models;

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

        public TodoController(TodoContext context)
        {
            _context = context;

            if (_context.TodoItems.Count() == 0)
            {
                _context.TodoItems.Add(new TodoItem { Name = "Item1" });
                _context.SaveChanges();
            }
        }
    }
}

```

The preceding code defines an API controller class without methods. In the next sections, methods are added to implement the API.

```

using Microsoft.AspNetCore.Mvc;
using System.Collections.Generic;
using System.Linq;
using TodoApi.Models;

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    [ApiController]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

        public TodoController(TodoContext context)
        {
            _context = context;

            if (_context.TodoItems.Count() == 0)
            {
                _context.TodoItems.Add(new TodoItem { Name = "Item1" });
                _context.SaveChanges();
            }
        }
    }
}

```

The preceding code defines an API controller class without methods. In the next sections, methods are added to implement the API. The class is annotated with an `[ApiController]` attribute to enable some convenient features. For information on features enabled by the attribute, see [Annotate class with ApiControllerAttribute](#).

The controller's constructor uses [Dependency Injection](#) to inject the database context (`TodoContext`) into the controller. The database context is used in each of the [CRUD](#) methods in the controller. The constructor adds an item to the in-memory database if one doesn't exist.

## Get to-do items

To get to-do items, add the following methods to the `TodoController` class:

```
[HttpGet]
public List<TodoItem> GetAll()
{
    return _context.TodoItems.ToList();
}

[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}
```

```
[HttpGet]
public ActionResult<List<TodoItem>> GetAll()
{
    return _context.TodoItems.ToList();
}

[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}
```

These methods implement the two GET methods:

- `GET /api/todo`
- `GET /api/todo/{id}`

Here's a sample HTTP response for the `GetAll` method:

```
[
{
    "id": 1,
    "name": "Item1",
    "isComplete": false
}]
```

Later in the tutorial, I'll show how the HTTP response can be viewed with [Postman](#) or [curl](#).

### Routing and URL paths

The `[HttpGet]` attribute denotes a method that responds to an HTTP GET request. The URL path for each method is constructed as follows:

- Take the template string in the controller's `Route` attribute:

```

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

```

```

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    [ApiController]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

```

- Replace `[controller]` with the name of the controller, which is the controller class name minus the "Controller" suffix. For this sample, the controller class name is **TodoController** and the root name is "todo". ASP.NET Core [routing](#) is case insensitive.
- If the `[HttpGet]` attribute has a route template (such as `[HttpGet("/products")]`), append that to the path. This sample doesn't use a template. For more information, see [Attribute routing with Http\[Verb\] attributes](#).

In the following  `GetById` method, `"{id}"` is a placeholder variable for the unique identifier of the to-do item. When  `GetById` is invoked, it assigns the value of `"{id}"` in the URL to the method's `id` parameter.

```

[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}

```

```

[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}

```

`Name = "GetTodo"` creates a named route. Named routes:

- Enable the app to create an HTTP link using the route name.
- Are explained later in the tutorial.

## Return values

The  `GetAll` method returns a collection of `TodoItem` objects. MVC automatically serializes the object to [JSON](#) and writes the JSON into the body of the response message. The response code for this method is 200, assuming there are no unhandled exceptions. Unhandled exceptions are translated into 5xx errors.

In contrast, the  `GetById` method returns the more general [IActionResult type](#), which represents a wide range of

return types.  `GetById` has two different return types:

- If no item matches the requested ID, the method returns a 404 error. Returning `NotFound` returns an HTTP 404 response.
- Otherwise, the method returns 200 with a JSON response body. Returning `Ok` results in an HTTP 200 response.

In contrast, the  `GetById` method returns the `ActionResult<T>` type, which represents a wide range of return types.  `GetById` has two different return types:

- If no item matches the requested ID, the method returns a 404 error. Returning `NotFound` returns an HTTP 404 response.
- Otherwise, the method returns 200 with a JSON response body. Returning `item` results in an HTTP 200 response.

## Launch the app

In Visual Studio, select **Run > Start With Debugging** to launch the app. Visual Studio launches a browser and navigates to `http://localhost:<port>`, where `<port>` is a randomly chosen port number. You get an HTTP 404 (Not Found) error. Change the URL to `http://localhost:<port>/api/values`. The `ValuesController` data is displayed:

```
["value1","value2"]
```

Navigate to the `Todo` controller at `http://localhost:<port>/api/todo`. The following JSON is returned:

```
[{"key":1,"name":"Item1","isComplete":false}]
```

## Implement the other CRUD operations

We'll add `Create`, `Update`, and `Delete` methods to the controller. These methods are variations on a theme, so I'll just show the code and highlight the main differences. Build the project after adding or changing code.

### Create

```
[HttpPost]
public IActionResult Create([FromBody] TodoItem item)
{
    if (item == null)
    {
        return BadRequest();
    }

    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}
```

The preceding method responds to an HTTP POST, as indicated by the `[HttpPost]` attribute. The `[FromBody]` attribute tells MVC to get the value of the to-do item from the body of the HTTP request.

```
[HttpPost]
public IActionResult Create(TodoItem item)
{
    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}
```

The preceding method responds to an HTTP POST, as indicated by the `[HttpPost]` attribute. MVC gets the value of the to-do item from the body of the HTTP request.

The `CreatedAtRoute` method returns a 201 response. It's the standard response for an HTTP POST method that creates a new resource on the server. `CreatedAtRoute` also adds a Location header to the response. The Location header specifies the URI of the newly created to-do item. See [10.2.2 201 Created](#).

### Use Postman to send a Create request

- Start the app ([Run > Start With Debugging](#)).
- Open Postman.

The screenshot shows the Postman application interface. The top navigation bar includes File, Edit, View, Help, New, Import, Runner, My Workspace (IN SYNC), and environment dropdown. The main area shows a POST request to `https://localhost:44375/api/todo`. The Body tab is selected, showing a raw JSON payload:

```
1 [ {
2     "name": "walk dog",
3     "isComplete": true
4 } ]
```

The Headers tab shows three entries: form-data, x-www-form-urlencoded, and raw (selected). The Content-Type is set to `JSON (application/json)`. The response section shows a status of `201 Created` and a time of `148 ms`. The Body tab displays the response JSON:

```
1 { "id": 6, "name": "walk dog", "isComplete": true }
```

- Update the port number in the localhost URL.
- Set the HTTP method to *POST*.
- Click the **Body** tab.
- Select the **raw** radio button.
- Set the type to *JSON (application/json)*.
- Enter a request body with a to-do item resembling the following JSON:

```
{  
    "name": "walk dog",  
    "isComplete": true  
}
```

- Click the **Send** button.

#### TIP

If no response displays after clicking **Send**, disable the **SSL certification verification** option. This is found under **File > Settings**. Click the **Send** button again after disabling the setting.

Click the **Headers** tab in the **Response** pane and copy the **Location** header value:

The screenshot shows the Postman application interface. A POST request is being made to `https://localhost:44375/api/todo`. The request body is set to `JSON (application/json)` and contains the following JSON payload:

```
1 [ {  
2     "name": "walk dog",  
3     "isComplete": true  
4 }]
```

The **Headers** tab is highlighted with a red box. The `Content-Type` header is listed as `application/json; charset=utf-8`. The `Location` header is listed as `https://localhost/api/Todo/6`, which is also highlighted with a red box. The status bar at the bottom right indicates `Status: 201 Created Time: 148 ms`.

You can use the **Location** header URI to access the resource you created. The `Create` method returns `CreatedAtRoute`. The first parameter passed to `CreatedAtRoute` represents the named route to use for generating the URL. Recall that the  `GetById` method created the `"GetTodo"` named route:

```
[HttpGet("{id}", Name = "GetTodo")]
```

## Update

```
[HttpPut("{id}")]
public IActionResult Update(long id, [FromBody] TodoItem item)
{
    if (item == null || item.Id != id)
    {
        return BadRequest();
    }

    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    todo.IsComplete = item.IsComplete;
    todo.Name = item.Name;

    _context.TodoItems.Update(todo);
    _context.SaveChanges();
    return NoContent();
}
```

```
[HttpPut("{id}")]
public IActionResult Update(long id, TodoItem item)
{
    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    todo.IsComplete = item.IsComplete;
    todo.Name = item.Name;

    _context.TodoItems.Update(todo);
    _context.SaveChanges();
    return NoContent();
}
```

`Update` is similar to `Create`, but uses HTTP PUT. The response is [204 \(No Content\)](#). According to the HTTP spec, a PUT request requires the client to send the entire updated entity, not just the deltas. To support partial updates, use HTTP PATCH.

```
{
  "key": 1,
  "name": "walk dog",
  "isComplete": true
}
```

The screenshot shows the Postman application interface. At the top, there are tabs for 'File', 'Edit', 'View', and 'Help'. Below the tabs are buttons for 'New', 'Import', 'Runner', and 'My Workspace'. The 'My Workspace' button has a status indicator 'IN SYNC'. On the right side of the header are icons for environment management, sync, and notifications.

The main workspace shows a request configuration. The method is set to 'PUT' (highlighted with a red box), the URL is 'https://localhost:44375/api/todo/1', and the 'Body' tab is selected (also highlighted with a red box). The 'Body' type is set to 'raw' (highlighted with a red box) and the content type is 'JSON (application/json)' (highlighted with a red box). The JSON payload is:

```
1 {  
2   "name": "walk cat",  
3   "isComplete": true  
4 }
```

Below the request configuration, the response section is visible. It shows the status as 'Status: 204 No Content' and the time taken as 'Time: 70 ms'. The 'Body' tab is selected, showing an empty response body. Other tabs like 'Cookies', 'Headers', and 'Test Results' are also present.

## Delete

```
[HttpDelete("{id}")]
public IActionResult Delete(long id)
{
    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    _context.TodoItems.Remove(todo);
    _context.SaveChanges();
    return NoContent();
}
```

The response is [204 \(No Content\)](#).

The screenshot shows the Postman application interface. At the top, there are tabs for 'File', 'Edit', 'View', and 'Help'. Below the tabs are buttons for 'New', 'Import', 'Runner', and a workspace dropdown labeled 'My Workspace IN SYNC'. There are also icons for environment management and notifications.

In the main area, there are three tabs for environments: 'https://localhost:4437' (red dot), 'https://localhost:4437' (red dot), and 'https://localhost:4437' (red dot). A '+' button and an '...' button are available for creating new environments. To the right, it says 'No Environment'.

The request details are shown in a red-bordered box:

- Method: **DELETE**
- URL: <https://localhost:44375/api/todo/1>
- Params: None
- Send: Blue button

Below the request details, there are tabs for 'Authorization', 'Headers', 'Body', 'Pre-request Script', and 'Tests'. The 'Authorization' tab is selected, showing 'TYPE' set to 'No Auth'. A note states: 'The authorization header will be automatically generated when you send the request. [Learn more about authorization](#)'.

The 'Body' tab is selected, showing 'Status: 204 No Content' and 'Time: 735 ms'. It has options for 'Pretty', 'Raw', 'Preview', 'Text' (with a dropdown arrow), and a copy icon. The preview area is empty, showing only the number '1'.

## Call the Web API with jQuery

In this section, an HTML page is added that uses jQuery to call the Web API. jQuery initiates the request and updates the page with the details from the API's response.

Configure the project to serve static files and to enable default file mapping. This is accomplished by invoking the `UseStaticFiles` and `UseDefaultFiles` extension methods in `Startup.Configure`. For more information, see [Static files](#).

```
public void Configure(IApplicationBuilder app)
{
    app.UseDefaultFiles();
    app.UseStaticFiles();
    app.UseMvc();
}
```

Add an HTML file, named `index.html`, to the project's `wwwroot` directory. Replace its contents with the following markup:

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="UTF-8">
    <title>To-do CRUD</title>
    <style>
        input[type='submit'], button, [aria-label] {
            cursor: pointer;
        }
    </style>

```

```

#spoiler {
    display: none;
}

table {
    font-family: Arial, sans-serif;
    border: 1px solid;
    border-collapse: collapse;
}

th {
    background-color: #0066CC;
    color: white;
}

td {
    border: 1px solid;
    padding: 5px;
}

```

</style>

</head>

<body>

<h1>To-do CRUD</h1>

<h3>Add</h3>

<form action="javascript:void(0);" method="POST" onsubmit="addItem()">

<input type="text" id="add-name" placeholder="New to-do">

<input type="submit" value="Add">

</form>

<div id="spoiler">

<h3>Edit</h3>

<form class="my-form">

<input type="hidden" id="edit-id">

<input type="checkbox" id="edit-isComplete">

<input type="text" id="edit-name">

<input type="submit" value="Edit">

<a onclick="closeInput()" aria-label="Close">Close</a>

</form>

</div>

<p id="counter"></p>

<table>

<tr>

<th>Is Complete</th>

<th>Name</th>

<th></th>

<th></th>

</tr>

<tbody id="todos"></tbody>

</table>

<script src="https://code.jquery.com/jquery-3.3.1.min.js"
 integrity="sha256-FgpCb/KJQlLNfOu91ta32o/NMZxltwRo8QtmkMRdAu8="
 crossorigin="anonymous"></script>

<script src="site.js"></script>

</body>

</html>

Add a JavaScript file, named *site.js*, to the project's *wwwroot* directory. Replace its contents with the following code:

```

const uri = 'api/todo';
let todos = null;
function getCount(data) {
    const el = $('#counter');
    let name = 'to-do';
    if (data) {

```

```

        if (data > 1) {
            name = 'to-dos';
        }
        el.text(data + ' ' + name);
    } else {
        el.html('No ' + name);
    }
}

$(document).ready(function () {
    getData();
});

function getData() {
    $.ajax({
        type: 'GET',
        url: uri,
        success: function (data) {
            $('#todos').empty();
            getCount(data.length);
            $.each(data, function (key, item) {
                const checked = item.isComplete ? 'checked' : '';

                $('<tr><td><input disabled="true" type="checkbox" ' + checked + '></td>' +
                    '<td>' + item.name + '</td>' +
                    '<td><button onclick="editItem(' + item.id + ')>Edit</button></td>' +
                    '<td><button onclick="deleteItem(' + item.id + ')>Delete</button></td>' +
                    '</tr>').appendTo($('#todos'));
            });
        }
    });
}

function addItem() {
    const item = {
        'name': $('#add-name').val(),
        'isComplete': false
    };

    $.ajax({
        type: 'POST',
        accepts: 'application/json',
        url: uri,
        contentType: 'application/json',
        data: JSON.stringify(item),
        error: function (jqXHR, textStatus, errorThrown) {
            alert('here');
        },
        success: function (result) {
            getData();
            $('#add-name').val('');
        }
    });
}

function deleteItem(id) {
    $.ajax({
        url: uri + '/' + id,
        type: 'DELETE',
        success: function (result) {
            getData();
        }
    });
}

function editItem(id) {
    $.each(todos, function (key, item) {

```

```

        if (item.id === id) {
            $('#edit-name').val(item.name);
            $('#edit-id').val(item.id);
            $('#edit-isComplete').val(item.isComplete);
        }
    });
    $('#spoiler').css({ 'display': 'block' });
}

$('.my-form').on('submit', function () {
    const item = {
        'name': $('#edit-name').val(),
        'isComplete': $('#edit-isComplete').is(':checked'),
        'id': $('#edit-id').val()
    };

    $.ajax({
        url: uri + '/' + $('#edit-id').val(),
        type: 'PUT',
        accepts: 'application/json',
        contentType: 'application/json',
        data: JSON.stringify(item),
        success: function (result) {
            getData();
        }
    });

    closeInput();
    return false;
});

function closeInput() {
    $('#spoiler').css({ 'display': 'none' });
}

```

A change to the ASP.NET Core project's launch settings may be required to test the HTML page locally. Open `launchSettings.json` in the *Properties* directory of the project. Remove the `launchUrl` property to force the app to open at `index.html`—the project's default file.

There are several ways to get jQuery. In the preceding snippet, the library is loaded from a CDN. This sample is a complete CRUD example of calling the API with jQuery. There are additional features in this sample to make the experience richer. Below are explanations around the calls to the API.

### Get a list of to-do items

To get a list of to-do items, send an HTTP GET request to `/api/todo`.

The jQuery `ajax` function sends an AJAX request to the API, which returns JSON representing an object or array. This function can handle all forms of HTTP interaction, sending an HTTP request to the specified `url`. `GET` is used as the `type`. The `success` callback function is invoked if the request succeeds. In the callback, the DOM is updated with the to-do information.

```

$(document).ready(function () {
    getData();
});

function getData() {
    $.ajax({
        type: 'GET',
        url: uri,
        success: function (data) {
            $('#todos').empty();
            getCount(data.length);
            $.each(data, function (key, item) {
                const checked = item.isComplete ? 'checked' : '';

                $('<tr><td><input disabled="true" type="checkbox" ' + checked + '></td>' +
                    '<td>' + item.name + '</td>' +
                    '<td><button onclick="editItem(' + item.id + ')>Edit</button></td>' +
                    '<td><button onclick="deleteItem(' + item.id + ')>Delete</button></td>' +
                    '</tr>').appendTo($('#todos'));
            });
        }
    });
}

```

## Add a to-do item

To add a to-do item, send an HTTP POST request to `/api/todo/`. The request body should contain a to-do object. The `ajax` function is using `POST` to call the API. For `POST` and `PUT` requests, the request body represents the data sent to the API. The API is expecting a JSON request body. The `accepts` and `contentType` options are set to `application/json` to classify the media type being received and sent, respectively. The data is converted to a JSON object using `JSON.stringify`. When the API returns a successful status code, the `getData` function is invoked to update the HTML table.

```

function addItem() {
    const item = {
        'name': $('#add-name').val(),
        'isComplete': false
    };

    $.ajax({
        type: 'POST',
        accepts: 'application/json',
        url: uri,
        contentType: 'application/json',
        data: JSON.stringify(item),
        error: function (jqXHR, textStatus, errorThrown) {
            alert('here');
        },
        success: function (result) {
            getData();
            $('#add-name').val('');
        }
    });
}

```

## Update a to-do item

Updating a to-do item is very similar to adding one, since both rely on a request body. The only real difference between the two in this case is that the `url` changes to add the unique identifier of the item, and the `type` is `PUT`.

```
$.ajax({
    url: uri + '/' + $('#edit-id').val(),
    type: 'PUT',
    accepts: 'application/json',
    contentType: 'application/json',
    data: JSON.stringify(item),
    success: function (result) {
        getData();
    }
});
```

## Delete a to-do item

Deleting a to-do item is accomplished by setting the `type` on the AJAX call to `DELETE` and specifying the item's unique identifier in the URL.

```
$.ajax({
    url: uri + '/' + id,
    type: 'DELETE',
    success: function (result) {
        getData();
    }
});
```

## Next steps

# Create a Web API with ASP.NET Core and Visual Studio for Windows

6/21/2018 • 15 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Mike Wasson](#)

This tutorial builds a web API for managing a list of "to-do" items. A user interface (UI) isn't created.

There are three versions of this tutorial:

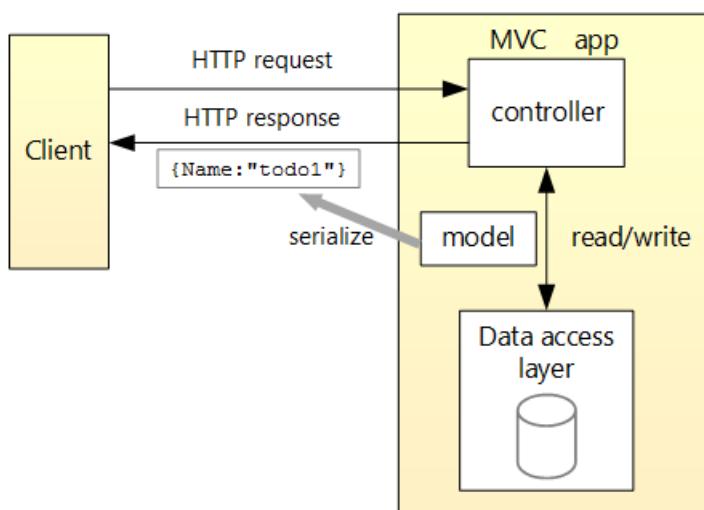

- Windows: Web API with Visual Studio for Windows (This tutorial)
- macOS: [Web API with Visual Studio for Mac](#)
- macOS, Linux, Windows: [Web API with Visual Studio Code](#)

## Overview

This tutorial creates the following API:

API	DESCRIPTION	REQUEST BODY	RESPONSE BODY
GET /api/todo	Get all to-do items	None	Array of to-do items
GET /api/todo/{id}	Get an item by ID	None	To-do item
POST /api/todo	Add a new item	To-do item	To-do item
PUT /api/todo/{id}	Update an existing item	To-do item	None
DELETE /api/todo/{id}	Delete an item	None	None

The following diagram shows the basic design of the app.

- The client is whatever consumes the web API (mobile app, browser, etc.). This tutorial doesn't create a client. [Postman](#) or [curl](#) is used as the client to test the app.
- A *model* is an object that represents the data in the app. In this case, the only model is a to-do item. Models are represented as C# classes, also known as **Plain Old CLR Object** (POCOs).

- A *controller* is an object that handles HTTP requests and creates the HTTP response. This app has a single controller.
- To keep the tutorial simple, the app doesn't use a persistent database. The sample app stores to-do items in an in-memory database.

## Prerequisites

Visual Studio 2017 version 15.7.3 or later with the following workloads:

- **ASP.NET and web development**
- **.NET Core cross-platform development**

.NET Core 2.1 SDK or later

## Create the project

Follow these steps in Visual Studio:

- From the **File** menu, select **New > Project**.
- Select the **ASP.NET Core Web Application** template. Name the project *TodoApi* and click **OK**.
- In the **New ASP.NET Core Web Application - TodoApi** dialog, choose the ASP.NET Core version. Select the **API** template and click **OK**. Do **not** select **Enable Docker Support**.

### Launch the app

In Visual Studio, press CTRL+F5 to launch the app. Visual Studio launches a browser and navigates to `http://localhost:<port>/api/values`, where `<port>` is a randomly chosen port number. Chrome, Microsoft Edge, and Firefox display the following output:

```
[ "value1", "value2" ]
```

If using Internet Explorer, you'll be prompted to save a *values.json* file.

### Add a model class

A model is an object representing the data in the app. In this case, the only model is a to-do item.

In Solution Explorer, right-click the project. Select **Add > New Folder**. Name the folder *Models*.

#### NOTE

The model classes can go anywhere in the project. The *Models* folder is used by convention for model classes.

In Solution Explorer, right-click the *Models* folder and select **Add > Class**. Name the class *TodoItem* and click **Add**.

Update the `TodoItem` class with the following code:

```
namespace TodoApi.Models
{
    public class TodoItem
    {
        public long Id { get; set; }
        public string Name { get; set; }
        public bool IsComplete { get; set; }
    }
}
```

The database generates the `Id` when a `TodoItem` is created.

## Create the database context

The *database context* is the main class that coordinates Entity Framework functionality for a given data model. This class is created by deriving from the `Microsoft.EntityFrameworkCore.DbContext` class.

In Solution Explorer, right-click the *Models* folder and select **Add > Class**. Name the class *TodoContext* and click **Add**.

Replace the class with the following code:

```
using Microsoft.EntityFrameworkCore;

namespace TodoApi.Models
{
    public class TodoContext : DbContext
    {
        public TodoContext(DbContextOptions<TodoContext> options)
            : base(options)
        {
        }

        public DbSet<TodoItem> TodoItems { get; set; }
    }
}
```

## Register the database context

In this step, the database context is registered with the [dependency injection](#) container. Services (such as the DB context) that are registered with the dependency injection (DI) container are available to the controllers.

Register the DB context with the service container using the built-in support for [dependency injection](#). Replace the contents of the *Startup.cs* file with the following code:

```

using Microsoft.AspNetCore.Builder;
using Microsoft.AspNetCore.Mvc;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using TodoApi.Models;

namespace TodoApi
{
    public class Startup
    {
        public void ConfigureServices(IServiceCollection services)
        {
            services.AddDbContext<TodoContext>(opt =>
                opt.UseInMemoryDatabase("TodoList"));
            services.AddMvc()
                .SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
        }

        public void Configure(IApplicationBuilder app)
        {
            app.UseMvc();
        }
    }
}

```

```

using Microsoft.AspNetCore.Builder;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using TodoApi.Models;

namespace TodoApi
{
    public class Startup
    {
        public void ConfigureServices(IServiceCollection services)
        {
            services.AddDbContext<TodoContext>(opt =>
                opt.UseInMemoryDatabase("TodoList"));
            services.AddMvc();
        }

        public void Configure(IApplicationBuilder app)
        {
            app.UseMvc();
        }
    }
}

```

The preceding code:

- Removes the unused code.
- Specifies an in-memory database is injected into the service container.

## Add a controller

In Solution Explorer, right-click the *Controllers* folder. Select **Add > New Item**. In the **Add New Item** dialog, select the **API Controller Class** template. Name the class *TodoController*, and click **Add**.

Replace the class with the following code:

```
using Microsoft.AspNetCore.Mvc;
using System.Collections.Generic;
using System.Linq;
using TodoApi.Models;

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

        public TodoController(TodoContext context)
        {
            _context = context;

            if (_context.TodoItems.Count() == 0)
            {
                _context.TodoItems.Add(new TodoItem { Name = "Item1" });
                _context.SaveChanges();
            }
        }
    }
}
```

The preceding code defines an API controller class without methods. In the next sections, methods are added to implement the API.

```

using Microsoft.AspNetCore.Mvc;
using System.Collections.Generic;
using System.Linq;
using TodoApi.Models;

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    [ApiController]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

        public TodoController(TodoContext context)
        {
            _context = context;

            if (_context.TodoItems.Count() == 0)
            {
                _context.TodoItems.Add(new TodoItem { Name = "Item1" });
                _context.SaveChanges();
            }
        }
    }
}

```

The preceding code defines an API controller class without methods. In the next sections, methods are added to implement the API. The class is annotated with an `[ApiController]` attribute to enable some convenient features. For information on features enabled by the attribute, see [Annotate class with ApiControllerAttribute](#).

The controller's constructor uses [Dependency Injection](#) to inject the database context (`TodoContext`) into the controller. The database context is used in each of the [CRUD](#) methods in the controller. The constructor adds an item to the in-memory database if one doesn't exist.

## Get to-do items

To get to-do items, add the following methods to the `TodoController` class:

```

[HttpGet]
public List<TodoItem> GetAll()
{
    return _context.TodoItems.ToList();
}

[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}

```

```

[HttpGet]
public ActionResult<List<TodoItem>> GetAll()
{
    return _context.TodoItems.ToList();
}

[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}

```

These methods implement the two GET methods:

- `GET /api/todo`
- `GET /api/todo/{id}`

Here's a sample HTTP response for the `GetAll` method:

```
[
{
    "id": 1,
    "name": "Item1",
    "isComplete": false
}
]
```

Later in the tutorial, I'll show how the HTTP response can be viewed with [Postman](#) or [curl](#).

## Routing and URL paths

The `[HttpGet]` attribute denotes a method that responds to an HTTP GET request. The URL path for each method is constructed as follows:

- Take the template string in the controller's `Route` attribute:

```

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;
    }
}
```

```

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    [ApiController]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;
    }
}
```

- Replace `[controller]` with the name of the controller, which is the controller class name minus the "Controller" suffix. For this sample, the controller class name is **TodoController** and the root name is "todo". ASP.NET Core [routing](#) is case insensitive.

- If the `[HttpGet]` attribute has a route template (such as `[HttpGet("/products")]`), append that to the path. This sample doesn't use a template. For more information, see [Attribute routing with Http\[Verb\] attributes](#).

In the following  `GetById` method, `"{id}"` is a placeholder variable for the unique identifier of the to-do item. When  `GetById` is invoked, it assigns the value of `"{id}"` in the URL to the method's `id` parameter.

```
[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}
```

```
[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}
```

`Name = "GetTodo"` creates a named route. Named routes:

- Enable the app to create an HTTP link using the route name.
- Are explained later in the tutorial.

## Return values

The  `GetAll` method returns a collection of  `TodoItem` objects. MVC automatically serializes the object to [JSON](#) and writes the JSON into the body of the response message. The response code for this method is 200, assuming there are no unhandled exceptions. Unhandled exceptions are translated into 5xx errors.

In contrast, the  `GetById` method returns the more general [IActionResult type](#), which represents a wide range of return types.  `GetById` has two different return types:

- If no item matches the requested ID, the method returns a 404 error. Returning `NotFound` returns an HTTP 404 response.
- Otherwise, the method returns 200 with a JSON response body. Returning `Ok` results in an HTTP 200 response.

In contrast, the  `GetById` method returns the [ActionResult<T> type](#), which represents a wide range of return types.  `GetById` has two different return types:

- If no item matches the requested ID, the method returns a 404 error. Returning `NotFound` returns an HTTP 404 response.
- Otherwise, the method returns 200 with a JSON response body. Returning `item` results in an HTTP 200 response.

## Launch the app

In Visual Studio, press CTRL+F5 to launch the app. Visual Studio launches a browser and navigates to `http://localhost:<port>/api/values`, where `<port>` is a randomly chosen port number. Navigate to the  `Todo`

controller at `http://localhost:<port>/api/todo`.

## Implement the other CRUD operations

In the following sections, `Create`, `Update`, and `Delete` methods are added to the controller.

### Create

Add the following `Create` method:

```
[HttpPost]
public IActionResult Create([FromBody] TodoItem item)
{
    if (item == null)
    {
        return BadRequest();
    }

    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}
```

The preceding code is an HTTP POST method, as indicated by the `[HttpPost]` attribute. The `[FromBody]` attribute tells MVC to get the value of the to-do item from the body of the HTTP request.

```
[HttpPost]
public IActionResult Create(TodoItem item)
{
    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}
```

The preceding code is an HTTP POST method, as indicated by the `[HttpPost]` attribute. MVC gets the value of the to-do item from the body of the HTTP request.

The `CreatedAtRoute` method:

- Returns a 201 response. HTTP 201 is the standard response for an HTTP POST method that creates a new resource on the server.
- Adds a Location header to the response. The Location header specifies the URI of the newly created to-do item. See [10.2.2 201 Created](#).
- Uses the "GetTodo" named route to create the URL. The "GetTodo" named route is defined in  `GetById`:

```
[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}
```

```
[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}
```

### Use Postman to send a Create request

- Start the app.
- Open Postman.

The screenshot shows the Postman application window. At the top, the URL is set to `https://localhost:44375/api/todo`. The method dropdown is set to `POST`. The `Body` tab is selected, and the type is set to `raw` with `JSON (application/json)` selected. The request body contains the following JSON:

```
1 {{"name": "walk dog", "isComplete": true}}
```

In the bottom section, the `Body` tab is active, showing the response body which is identical to the request body. The status is listed as `Status: 201 Created Time: 148 ms`.

- Update the port number in the localhost URL.
- Set the HTTP method to `POST`.
- Click the **Body** tab.
- Select the **raw** radio button.
- Set the type to `JSON (application/json)`.
- Enter a request body with a to-do item resembling the following JSON:

```
{  
  "name": "walk dog",  
  "isComplete": true  
}
```

- Click the **Send** button.

#### TIP

If no response displays after clicking **Send**, disable the **SSL certification verification** option. This is found under **File > Settings**. Click the **Send** button again after disabling the setting.

Click the **Headers** tab in the **Response** pane and copy the **Location** header value:

The screenshot shows the Postman application interface. At the top, there's a navigation bar with File, Edit, View, Help, and a workspace dropdown set to My Workspace. Below the bar, a search bar contains the URL https://localhost:4437. To the right of the search bar are three buttons: a plus sign, a three-dot ellipsis, and a refresh icon. On the far right of the bar, it says 'No Environment' with a dropdown arrow. The main workspace has a 'POST' method selected and the URL https://localhost:44375/api/todo. To the right of the URL are Params and Send buttons. Below the URL, tabs for Authorization, Headers (3), Body (selected), Pre-request Script, and Tests are visible. Under the Body tab, there's a JSON editor with the following content:

```
1 [{}  
2   "name": "walk dog",  
3   "isComplete": true  
4 ]
```

Below the JSON editor, the Headers tab is highlighted with a red box. It shows seven headers: Content-Type → application/json; charset=utf-8, Date → Fri, 27 Apr 2018 18:32:32 GMT, and Location → https://localhost/api/Todo/6. The Location header is also highlighted with a red box. At the bottom of the interface, there are icons for refresh, search, and file operations, along with a BUILD dropdown and a lightbulb icon.

The Location header URI can be used to access the new item.

#### Update

Add the following **Update** method:

```
[HttpPut("{id}")]
public IActionResult Update(long id, [FromBody] TodoItem item)
{
    if (item == null || item.Id != id)
    {
        return BadRequest();
    }

    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    todo.IsComplete = item.IsComplete;
    todo.Name = item.Name;

    _context.TodoItems.Update(todo);
    _context.SaveChanges();
    return NoContent();
}
```

```
[HttpPut("{id}")]
public IActionResult Update(long id, TodoItem item)
{
    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    todo.IsComplete = item.IsComplete;
    todo.Name = item.Name;

    _context.TodoItems.Update(todo);
    _context.SaveChanges();
    return NoContent();
}
```

`Update` is similar to `Create`, except it uses HTTP PUT. The response is [204 \(No Content\)](#). According to the HTTP specification, a PUT request requires the client to send the entire updated entity, not just the deltas. To support partial updates, use HTTP PATCH.

Use Postman to update the to-do item's name to "walk cat":

The screenshot shows the Postman application interface. At the top, there are tabs for 'File', 'Edit', 'View', and 'Help'. Below the tabs, there are buttons for 'New', 'Import', 'Runner', and 'My Workspace'. The 'My Workspace' button has a dropdown arrow. To the right of the workspace button are icons for 'IN SYNC', a globe, a user profile, and notifications. The main workspace shows two tabs: 'https://localhost:4437' and 'https://localhost:4437'. There are buttons for '+', '...', and 'No Environment'. Below the tabs, a red box highlights the 'PUT' method dropdown. The URL 'https://localhost:44375/api/todo/1' is entered. To the right are buttons for 'Params' and 'Send'. Underneath the URL, there are tabs for 'Authorization', 'Headers (3)', 'Body (●)', 'Pre-request Script', and 'Tests'. A red box highlights the 'Body' tab. Below the tabs, there are four radio buttons: 'form-data', 'x-www-form-urlencoded', 'raw' (which is selected and highlighted with a red box), and 'binary'. A red box also highlights the 'JSON (application/json)' dropdown. The 'Body' section contains a code editor with the following JSON:

```
1 {  
2   "name": "walk cat",  
3   "isComplete": true  
4 }
```

## Delete

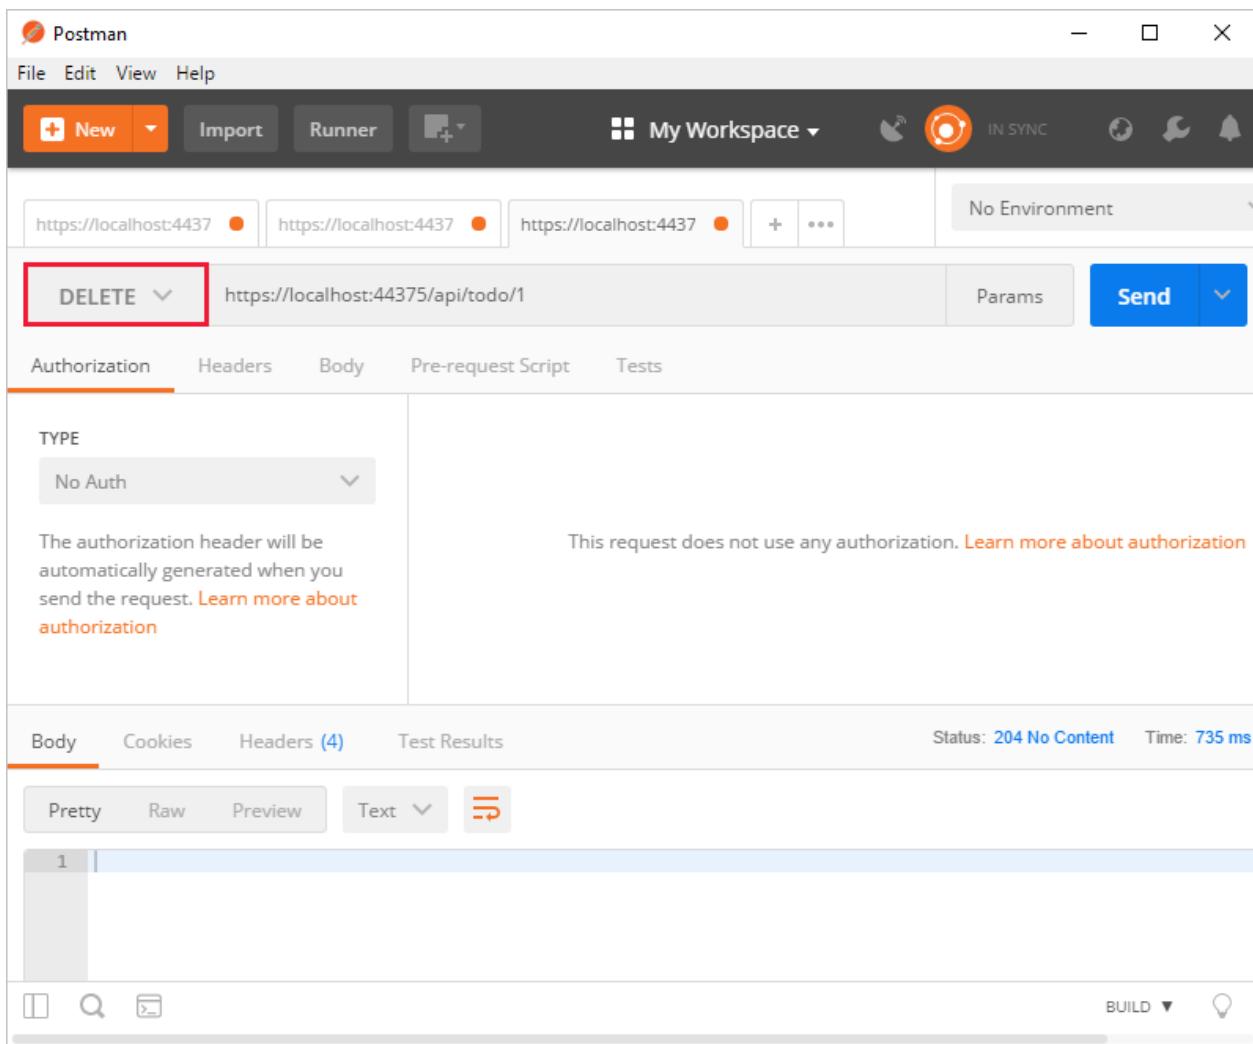

Add the following `Delete` method:

```
[HttpDelete("{id}")]
public IActionResult Delete(long id)
{
    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    _context.TodoItems.Remove(todo);
    _context.SaveChanges();
    return NoContent();
}
```

The `Delete` response is [204 \(No Content\)](#).

Use Postman to delete the to-do item:

## Call the Web API with jQuery

In this section, an HTML page is added that uses jQuery to call the Web API. jQuery initiates the request and updates the page with the details from the API's response.

Configure the project to serve static files and to enable default file mapping. This is accomplished by invoking the [UseStaticFiles](#) and [UseDefaultFiles](#) extension methods in *Startup.Configure*. For more information, see [Static files](#).

```
public void Configure(IApplicationBuilder app)
{
    app.UseDefaultFiles();
    app.UseStaticFiles();
    app.UseMvc();
}
```

Add an HTML file, named *index.html*, to the project's *wwwroot* directory. Replace its contents with the following markup:

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="UTF-8">
    <title>To-do CRUD</title>
    <style>
        input[type='submit'], button, [aria-label] {
            cursor: pointer;
        }
    </style>

```

```

#spoiler {
    display: none;
}

table {
    font-family: Arial, sans-serif;
    border: 1px solid;
    border-collapse: collapse;
}

th {
    background-color: #0066CC;
    color: white;
}

td {
    border: 1px solid;
    padding: 5px;
}

```

</style>

</head>

<body>

<h1>To-do CRUD</h1>

<h3>Add</h3>

<form action="javascript:void(0);" method="POST" onsubmit="addItem()">

<input type="text" id="add-name" placeholder="New to-do">

<input type="submit" value="Add">

</form>

<div id="spoiler">

<h3>Edit</h3>

<form class="my-form">

<input type="hidden" id="edit-id">

<input type="checkbox" id="edit-isComplete">

<input type="text" id="edit-name">

<input type="submit" value="Edit">

<a onclick="closeInput()" aria-label="Close">#10006;</a>

</form>

</div>

<p id="counter"></p>

<table>

<tr>

<th>Is Complete</th>

<th>Name</th>

<th></th>

<th></th>

</tr>

<tbody id="todos"></tbody>

</table>

<script src="https://code.jquery.com/jquery-3.3.1.min.js"
 integrity="sha256-FgpCb/KJQlLNf0u91ta32o/NMZxltwRo8QtmkMRdAu8="
 crossorigin="anonymous"></script>

<script src="site.js"></script>

</body>

</html>

Add a JavaScript file, named *site.js*, to the project's *wwwroot* directory. Replace its contents with the following code:

```

const uri = 'api/todo';
let todos = null;
function getCount(data) {
    const el = $('#counter');

```

```

let name = 'to-do';
if (data) {
    if (data > 1) {
        name = 'to-dos';
    }
    el.text(data + ' ' + name);
} else {
    el.html('No ' + name);
}
}

$(document).ready(function () {
    getData();
});

function getData() {
$.ajax({
    type: 'GET',
    url: uri,
    success: function (data) {
        $('#todos').empty();
        getCount(data.length);
        $.each(data, function (key, item) {
            const checked = item.isComplete ? 'checked' : '';
            $('<tr><td><input disabled="true" type="checkbox" ' + checked + '></td>' +
                '<td>' + item.name + '</td>' +
                '<td><button onclick="editItem(' + item.id + ')">Edit</button></td>' +
                '<td><button onclick="deleteItem(' + item.id + ')">Delete</button></td>' +
                '</tr>').appendTo($('#todos'));
        });
        todos = data;
    }
});
}

function addItem() {
const item = {
    'name': $('#add-name').val(),
    'isComplete': false
};

$.ajax({
    type: 'POST',
    accepts: 'application/json',
    url: uri,
    contentType: 'application/json',
    data: JSON.stringify(item),
    error: function (jqXHR, textStatus, errorThrown) {
        alert('here');
    },
    success: function (result) {
        getData();
        $('#add-name').val('');
    }
});
}

function deleteItem(id) {
$.ajax({
    url: uri + '/' + id,
    type: 'DELETE',
    success: function (result) {
        getData();
    }
});
}

```

```

function editItem(id) {
    $.each(todos, function (key, item) {
        if (item.id === id) {
            $('#edit-name').val(item.name);
            $('#edit-id').val(item.id);
            $('#edit-isComplete').val(item.isComplete);
        }
    });
    $('#spoiler').css({ 'display': 'block' });
}

$('.my-form').on('submit', function () {
    const item = {
        'name': $('#edit-name').val(),
        'isComplete': $('#edit-isComplete').is(':checked'),
        'id': $('#edit-id').val()
    };

    $.ajax({
        url: uri + '/' + $('#edit-id').val(),
        type: 'PUT',
        accepts: 'application/json',
        contentType: 'application/json',
        data: JSON.stringify(item),
        success: function (result) {
            getData();
        }
    });

    closeInput();
    return false;
});

function closeInput() {
    $('#spoiler').css({ 'display': 'none' });
}

```

A change to the ASP.NET Core project's launch settings may be required to test the HTML page locally. Open *launchSettings.json* in the *Properties* directory of the project. Remove the `launchUrl` property to force the app to open at *index.html*—the project's default file.

There are several ways to get jQuery. In the preceding snippet, the library is loaded from a CDN. This sample is a complete CRUD example of calling the API with jQuery. There are additional features in this sample to make the experience richer. Below are explanations around the calls to the API.

### Get a list of to-do items

To get a list of to-do items, send an HTTP GET request to `/api/todo`.

The jQuery `ajax` function sends an AJAX request to the API, which returns JSON representing an object or array. This function can handle all forms of HTTP interaction, sending an HTTP request to the specified `url`. `GET` is used as the `type`. The `success` callback function is invoked if the request succeeds. In the callback, the DOM is updated with the to-do information.

```

$(document).ready(function () {
    getData();
});

function getData() {
    $.ajax({
        type: 'GET',
        url: uri,
        success: function (data) {
            $('#todos').empty();
            getCount(data.length);
            $.each(data, function (key, item) {
                const checked = item.isComplete ? 'checked' : '';

                $('<tr><td><input disabled="true" type="checkbox" ' + checked + '></td>' +
                    '<td>' + item.name + '</td>' +
                    '<td><button onclick="editItem(' + item.id + ')>Edit</button></td>' +
                    '<td><button onclick="deleteItem(' + item.id + ')>Delete</button></td>' +
                    '</tr>').appendTo($('#todos'));
            });
        }
    });

    todos = data;
}
});

```

## Add a to-do item

To add a to-do item, send an HTTP POST request to `/api/todo/`. The request body should contain a to-do object. The `ajax` function is using `POST` to call the API. For `POST` and `PUT` requests, the request body represents the data sent to the API. The API is expecting a JSON request body. The `accepts` and `contentType` options are set to `application/json` to classify the media type being received and sent, respectively. The data is converted to a JSON object using `JSON.stringify`. When the API returns a successful status code, the `getData` function is invoked to update the HTML table.

```

function addItem() {
    const item = {
        'name': $('#add-name').val(),
        'isComplete': false
    };

    $.ajax({
        type: 'POST',
        accepts: 'application/json',
        url: uri,
        contentType: 'application/json',
        data: JSON.stringify(item),
        error: function (jqXHR, textStatus, errorThrown) {
            alert('here');
        },
        success: function (result) {
            getData();
            $('#add-name').val('');
        }
    });
}

```

## Update a to-do item

Updating a to-do item is very similar to adding one, since both rely on a request body. The only real difference between the two in this case is that the `url` changes to add the unique identifier of the item, and the `type` is `PUT`.

```
$.ajax({
    url: uri + '/' + $('#edit-id').val(),
    type: 'PUT',
    accepts: 'application/json',
    contentType: 'application/json',
    data: JSON.stringify(item),
    success: function (result) {
        getData();
    }
});
```

## Delete a to-do item

Deleting a to-do item is accomplished by setting the `type` on the AJAX call to `DELETE` and specifying the item's unique identifier in the URL.

```
$.ajax({
    url: uri + '/' + id,
    type: 'DELETE',
    success: function (result) {
        getData();
    }
});
```

# Create backend services for native mobile apps with ASP.NET Core

6/21/2018 • 7 minutes to read • [Edit Online](#)

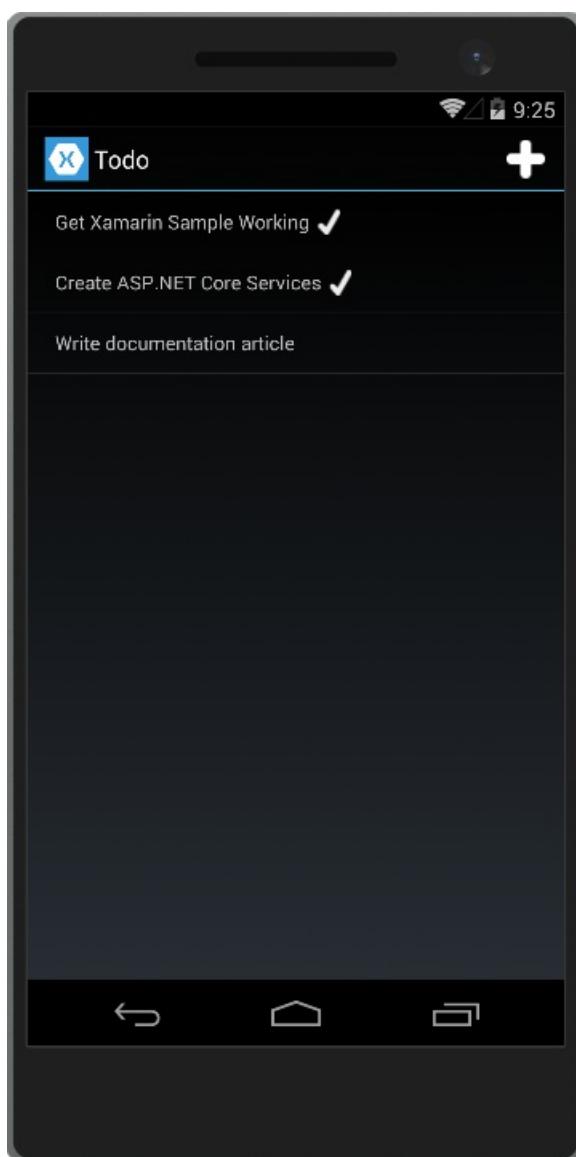

By [Steve Smith](#)

Mobile apps can easily communicate with ASP.NET Core backend services.

[View or download sample backend services code](#)

## The Sample Native Mobile App

This tutorial demonstrates how to create backend services using ASP.NET Core MVC to support native mobile apps. It uses the [Xamarin Forms ToDoRest app](#) as its native client, which includes separate native clients for Android, iOS, Windows Universal, and Window Phone devices. You can follow the linked tutorial to create the native app (and install the necessary free Xamarin tools), as well as download the Xamarin sample solution. The Xamarin sample includes an ASP.NET Web API 2 services project, which this article's ASP.NET Core app replaces (with no changes required by the client).

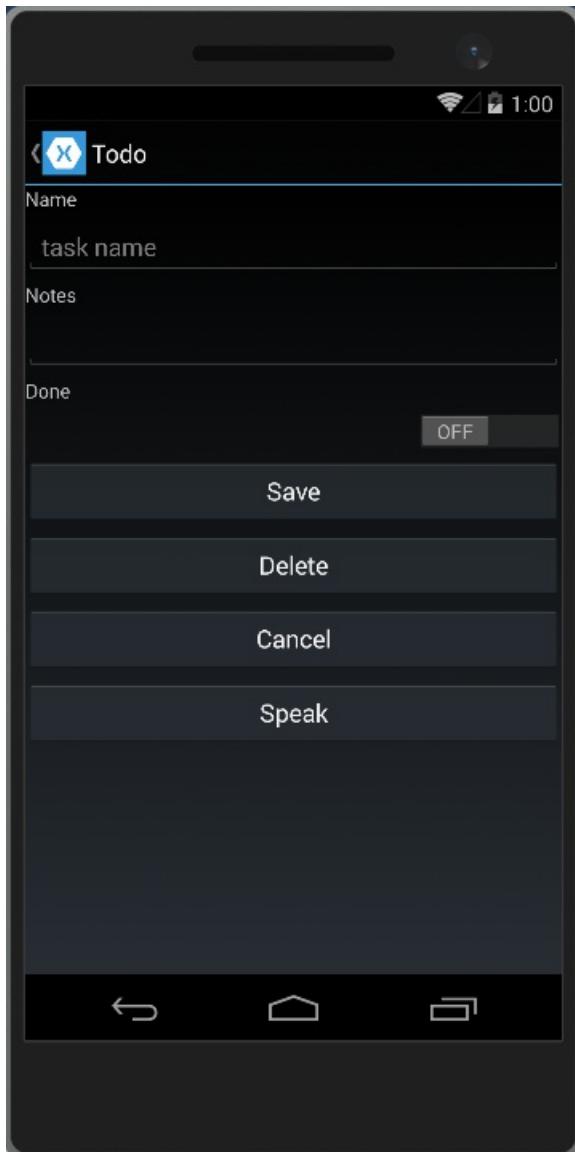

### Features

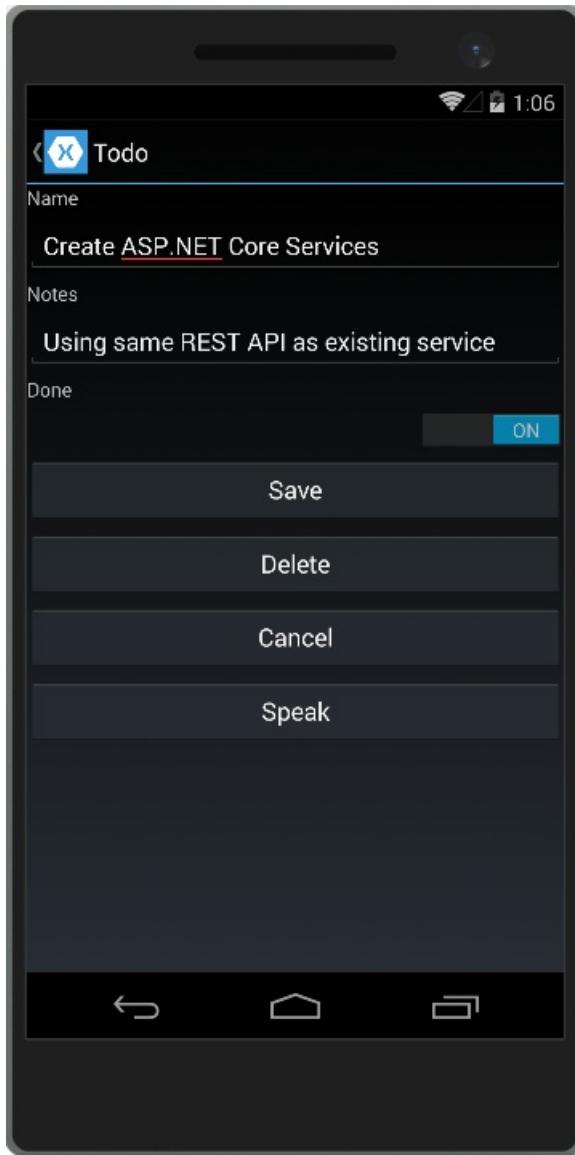

The ToDoRest app supports listing, adding, deleting, and updating To-Do items. Each item has an ID, a Name, Notes, and a property indicating whether it's been Done yet.

The main view of the items, as shown above, lists each item's name and indicates if it's done with a checkmark.

Tapping the  icon opens an add item dialog:

Tapping an item on the main list screen opens up an edit dialog where the item's Name, Notes, and Done settings can be modified, or the item can be deleted:

This sample is configured by default to use backend services hosted at developer.xamarin.com, which allow read-only operations. To test it out yourself against the ASP.NET Core app created in the next section running on your computer, you'll need to update the app's `RestUrl` constant. Navigate to the `ToDoREST` project and open the `Constants.cs` file. Replace the `RestUrl` with a URL that includes your machine's IP address (not localhost or 127.0.0.1, since this address is used from the device emulator, not from your machine). Include the port number as well (5000). In order to test that your services work with a device, ensure you don't have an active firewall blocking access to this port.

```
// URL of REST service (Xamarin ReadOnly Service)
//public static string RestUrl = "http://developer.xamarin.com:8081/api/todoitems{0}";

// use your machine's IP address
public static string RestUrl = "http://192.168.1.207:5000/api/todoitems/{0}";
```

## Creating the ASP.NET Core Project

Create a new ASP.NET Core Web Application in Visual Studio. Choose the Web API template and No Authentication. Name the project `ToDoApi`.

Select a template:

**ASP.NET Core Templates**

Empty

Web API

Web Application

A project template for creating an ASP.NET Core application with an example Controller for a RESTful HTTP service. This template can also be used for ASP.NET MVC Views and Controllers.

[Learn more](#)[Change Authentication](#)Authentication: **No Authentication**

Microsoft Azure

 Host in the cloud

App Service ▾

[OK](#)[Cancel](#)

The application should respond to all requests made to port 5000. Update *Program.cs* to include

```
.UseUrls("http://*:5000")
```

 to achieve this:

```
var host = new WebHostBuilder()
    .UseKestrel()
    .UseUrls("http://*:5000")
    .UseContentRoot(Directory.GetCurrentDirectory())
    .UseIISIntegration()
    .UseStartup<Startup>()
    .Build();
```

**NOTE**

Make sure you run the application directly, rather than behind IIS Express, which ignores non-local requests by default. Run [dotnet run](#) from a command prompt, or choose the application name profile from the Debug Target dropdown in the Visual Studio toolbar.

Add a model class to represent To-Do items. Mark required fields using the `[Required]` attribute:

```

using System.ComponentModel.DataAnnotations;

namespace ToDoApi.Models
{
    public class ToDoItem
    {
        [Required]
        public string ID { get; set; }

        [Required]
        public string Name { get; set; }

        [Required]
        public string Notes { get; set; }

        public bool Done { get; set; }
    }
}

```

The API methods require some way to work with data. Use the same `IToDoRepository` interface the original Xamarin sample uses:

```

using System.Collections.Generic;
using ToDoApi.Models;

namespace ToDoApi.Interfaces
{
    public interface IToDoRepository
    {
        bool DoesItemExist(string id);
        IEnumerable<ToDoItem> All { get; }
        ToDoItem Find(string id);
        void Insert(ToDoItem item);
        void Update(ToDoItem item);
        void Delete(string id);
    }
}

```

For this sample, the implementation just uses a private collection of items:

```

using System.Collections.Generic;
using System.Linq;
using ToDoApi.Interfaces;
using ToDoApi.Models;

namespace ToDoApi.Services
{
    public class ToDoRepository : IToDoRepository
    {
        private List<ToDoItem> _ToDoList;

        public ToDoRepository()
        {
            InitializeData();
        }

        public IEnumerable<ToDoItem> All
        {
            get { return _ToDoList; }
        }

        public bool DoesItemExist(string id)
        {
            return _ToDoList.Any(item => item.ID == id);
        }
    }
}

```

```

        }

        public ToDoItem Find(string id)
        {
            return _toDoList.FirstOrDefault(item => item.ID == id);
        }

        public void Insert(ToDoItem item)
        {
            _toDoList.Add(item);
        }

        public void Update(ToDoItem item)
        {
            var todoItem = this.Find(item.ID);
            var index = _toDoList.IndexOf(todoItem);
            _toDoList.RemoveAt(index);
            _toDoList.Insert(index, item);
        }

        public void Delete(string id)
        {
            _toDoList.Remove(this.Find(id));
        }

        private void InitializeData()
        {
            _toDoList = new List<ToDoItem>();

            var todoItem1 = new ToDoItem
            {
                ID = "6bb8a868-dba1-4f1a-93b7-24ebce87e243",
                Name = "Learn app development",
                Notes = "Attend Xamarin University",
                Done = true
            };

            var todoItem2 = new ToDoItem
            {
                ID = "b94afb54-a1cb-4313-8af3-b7511551b33b",
                Name = "Develop apps",
                Notes = "Use Xamarin Studio/Visual Studio",
                Done = false
            };

            var todoItem3 = new ToDoItem
            {
                ID = "ecfa6f80-3671-4911-aabe-63cc442c1ecf",
                Name = "Publish apps",
                Notes = "All app stores",
                Done = false,
            };

            _toDoList.Add(todoItem1);
            _toDoList.Add(todoItem2);
            _toDoList.Add(todoItem3);
        }
    }
}

```

Configure the implementation in *Startup.cs*:

```
public void ConfigureServices(IServiceCollection services)
{
    // Add framework services.
    services.AddMvc();

    services.AddSingleton<IToDoRepository, ToDoRepository>();
}
```

At this point, you're ready to create the *ToDoItemsController*.

**TIP**

Learn more about creating web APIs in [Build your first Web API with ASP.NET Core MVC and Visual Studio](#).

## Creating the Controller

Add a new controller to the project, *ToDoItemsController*. It should inherit from `Microsoft.AspNetCore.Mvc.Controller`. Add a `[Route]` attribute to indicate that the controller will handle requests made to paths starting with `api/todoitems`. The `[controller]` token in the route is replaced by the name of the controller (omitting the `Controller` suffix), and is especially helpful for global routes. Learn more about [routing](#).

The controller requires an `IToDoRepository` to function; request an instance of this type through the controller's constructor. At runtime, this instance will be provided using the framework's support for [dependency injection](#).

```
using System;
using Microsoft.AspNetCore.Http;
using Microsoft.AspNetCore.Mvc;
using ToDoApi.Interfaces;
using ToDoApi.Models;

namespace ToDoApi.Controllers
{
    [Route("api/[controller]")]
    public class ToDoItemsController : Controller
    {
        private readonly IToDoRepository _ToDoRepository;

        public ToDoItemsController(IToDoRepository ToDoRepository)
        {
            _ToDoRepository = ToDoRepository;
        }
    }
}
```

This API supports four different HTTP verbs to perform CRUD (Create, Read, Update, Delete) operations on the data source. The simplest of these is the Read operation, which corresponds to an HTTP GET request.

### Reading Items

Requesting a list of items is done with a GET request to the `List` method. The `[HttpGet]` attribute on the `List` method indicates that this action should only handle GET requests. The route for this action is the route specified on the controller. You don't necessarily need to use the action name as part of the route. You just need to ensure each action has a unique and unambiguous route. Routing attributes can be applied at both the controller and method levels to build up specific routes.

```
[HttpGet]
public IActionResult List()
{
    return Ok(_todoRepository.All);
}
```

The `List` method returns a 200 OK response code and all of the ToDo items, serialized as JSON.

You can test your new API method using a variety of tools, such as [Postman](#), shown here:

The screenshot shows the Postman application interface. At the top, there are tabs for Runner, Import, Builder, Team Library, and a sync status indicator. Below the header, the URL is set to `http://192.168.1.207:5000/api/todoitems`. The main interface shows a `GET` request has been sent, and the response body displays a JSON array of three todo items:

```
[{"id": "6bb8a868-dba1-4f1a-93b7-24ebce87e243", "name": "Learn app development", "notes": "Attend Xamarin University", "done": true}, {"id": "b94afb54-a1cb-4313-8af3-b7511551b33b", "name": "Develop apps", "notes": "Use Xamarin Studio/Visual Studio", "done": false}, {"id": "ecfa6f80-3671-4911-aabe-63cc442c1ecf", "name": "Publish apps", "notes": "All app stores", "done": false}]
```

## Creating Items

By convention, creating new data items is mapped to the HTTP POST verb. The `Create` method has an `[HttpPost]` attribute applied to it, and accepts a `ToDoItem` instance. Since the `item` argument will be passed in the body of the POST, this parameter is decorated with the `[FromBody]` attribute.

Inside the method, the item is checked for validity and prior existence in the data store, and if no issues occur, it's added using the repository. Checking `ModelState.IsValid` performs [model validation](#), and should be done in every API method that accepts user input.

```
[HttpPost]
public IActionResult Create([FromBody] ToDoItem item)
{
    try
    {
        if (item == null || !ModelState.IsValid)
        {
            return BadRequest(ErrorCode.TodoItemNameAndNotesRequired.ToString());
        }
        bool itemExists = _ToDoRepository.DoesItemExist(item.ID);
        if (itemExists)
        {
            return StatusCode(StatusCodes.Status409Conflict, ErrorCode.TodoItemIDInUse.ToString());
        }
        _ToDoRepository.Insert(item);
    }
    catch (Exception)
    {
        return BadRequest(ErrorCode.CouldNotCreateItem.ToString());
    }
    return Ok(item);
}
```

The sample uses an enum containing error codes that are passed to the mobile client:

```
public enum ErrorCode
{
    TodoItemNameAndNotesRequired,
    TodoItemIDInUse,
    RecordNotFound,
    CouldNotCreateItem,
    CouldNotUpdateItem,
    CouldNotDeleteItem
}
```

Test adding new items using Postman by choosing the POST verb providing the new object in JSON format in the Body of the request. You should also add a request header specifying a Content-Type of application/json.

The method returns the newly created item in the response.

## Updating Items

Modifying records is done using HTTP PUT requests. Other than this change, the `Edit` method is almost identical to `Create`. Note that if the record isn't found, the `Edit` action will return a `NotFound` (404) response.

```
[HttpPut]
public IActionResult Edit([FromBody] ToDoItem item)
{
    try
    {
        if (item == null || !ModelState.IsValid)
        {
            return BadRequest(ErrorCode.TodoItemNameAndNotesRequired.ToString());
        }
        var existingItem = _todoRepository.Find(item.ID);
        if (existingItem == null)
        {
            return NotFound(ErrorCode.RecordNotFound.ToString());
        }
        _todoRepository.Update(item);
    }
    catch (Exception)
    {
        return BadRequest(ErrorCode.CouldNotUpdateItem.ToString());
    }
    return NoContent();
}
```

To test with Postman, change the verb to PUT. Specify the updated object data in the Body of the request.

The screenshot shows the Postman application interface. The top navigation bar includes 'Runner', 'Import', 'Builder' (which is selected), 'Team Library', and various status indicators like 'SYNC OFF'. Below the header, the URL is set to `http://192.168.1.207:5000/a`. The main area shows a 'PUT' request to `http://192.168.1.207:5000/api/todoitems`. The 'Body' tab is active, showing a raw JSON payload:

```
1 {  
2     "ID": "6bb8b868-dba1-4f1a-93b7-24ebce87243",  
3     "Name": "An UPDATED Test Item",  
4     "Notes": "Some updated notes",  
5     "Done": true  
6 }
```

The 'Headers' section contains two entries: 'Content-Type: application/json' and 'Accept: application/json'. The 'Body' section is set to 'raw' and 'JSON (application/json)'. The response section shows a successful `204 No Content` response with a time of `91 ms`.

This method returns a `NoContent` (204) response when successful, for consistency with the pre-existing API.

## Deleting Items

Deleting records is accomplished by making DELETE requests to the service, and passing the ID of the item to be deleted. As with updates, requests for items that don't exist will receive `NotFound` responses. Otherwise, a successful request will get a `NoContent` (204) response.

```
[HttpDelete("{id}")]
public IActionResult Delete(string id)
{
    try
    {
        var item = _todoRepository.Find(id);
        if (item == null)
        {
            return NotFound(ErrorCode.RecordNotFound.ToString());
        }
        _todoRepository.Delete(id);
    }
    catch (Exception)
    {
        return BadRequest(ErrorCode.CouldNotDeleteItem.ToString());
    }
    return NoContent();
}
```

Note that when testing the delete functionality, nothing is required in the Body of the request.

The screenshot shows the Postman application interface. At the top, there are tabs for Runner, Import, Builder (which is selected), and Team Library. On the right side of the header, there are icons for a gear (Sync Off), a bell, and a dropdown menu. Below the header, the URL `http://192.168.1.207:5000/a` is entered in the address bar, along with a plus sign icon for creating new requests. To the right of the URL, it says "No environment" with a dropdown arrow and an eye icon. The main workspace shows a **DELETE** request to `http://192.168.1.207:5000/api/todoitems/6bb8b8`. The "Body" tab is selected, showing options for form-data, x-www-form-urlencoded, raw, and binary, with "raw" selected and "JSON (application/json)" chosen. A large text area for the request body is present but empty. Other tabs include Headers (2), Pre-request Script, Tests, and Generate Code. Below the request area, the response section is shown with "Body" selected. It displays the status `204 No Content` and time `91 ms`. It includes Pretty, Raw, Preview, and HTML buttons, and a search icon. A large text area for the response body is also empty.

## Common Web API Conventions

As you develop the backend services for your app, you will want to come up with a consistent set of conventions or policies for handling cross-cutting concerns. For example, in the service shown above, requests for specific records that weren't found received a `NotFound` response, rather than a `BadRequest` response. Similarly, commands made to this service that passed in model bound types always checked `ModelState.IsValid` and returned a `BadRequest` for invalid model types.

Once you've identified a common policy for your APIs, you can usually encapsulate it in a [filter](#). Learn more about [how to encapsulate common API policies in ASP.NET Core MVC applications](#).

# ASP.NET Core Web API help pages with Swagger / Open API

6/21/2018 • 2 minutes to read • [Edit Online](#)

By [Christoph Nienaber](#) and [Rico Suter](#)

When consuming a Web API, understanding its various methods can be challenging for a developer. [Swagger](#), also known as Open API, solves the problem of generating useful documentation and help pages for Web APIs. It provides benefits such as interactive documentation, client SDK generation, and API discoverability.

In this article, the [Swashbuckle.AspNetCore](#) and [NSwag](#) .NET Swagger implementations are showcased:

- **Swashbuckle.AspNetCore** is an open source project for generating Swagger documents for ASP.NET Core Web APIs.
- **NSwag** is another open source project for integrating [Swagger UI](#) or [ReDoc](#) into ASP.NET Core Web APIs. It offers approaches to generate C# and TypeScript client code for your API.

## What is Swagger / Open API?

Swagger is a language-agnostic specification for describing REST APIs. The Swagger project was donated to the [OpenAPI Initiative](#), where it's now referred to as Open API. Both names are used interchangeably; however, Open API is preferred. It allows both computers and humans to understand the capabilities of a service without any direct access to the implementation (source code, network access, documentation). One goal is to minimize the amount of work needed to connect disassociated services. Another goal is to reduce the amount of time needed to accurately document a service.

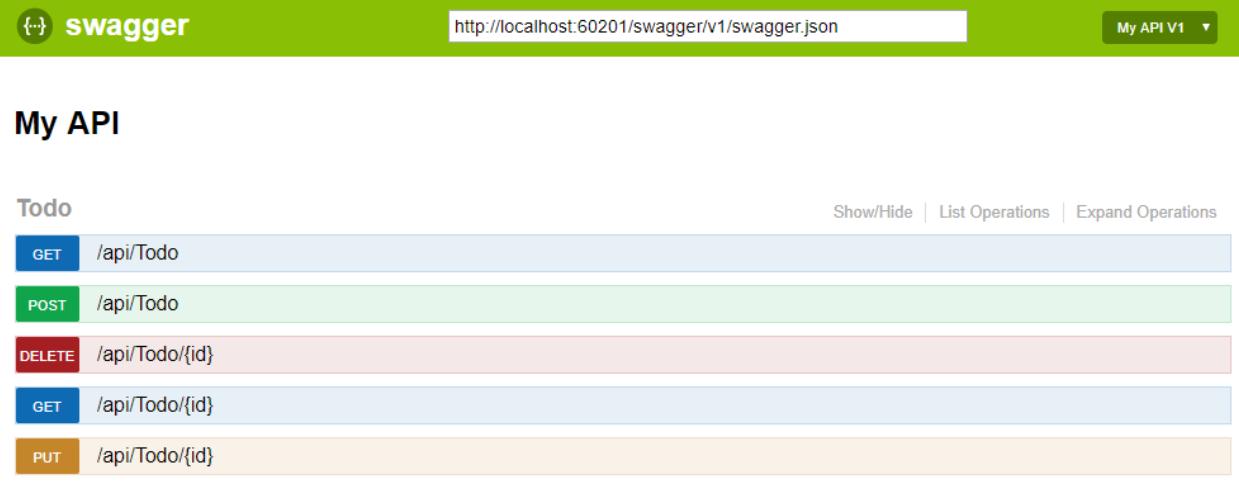

## Swagger specification (`swagger.json`)

The core to the Swagger flow is the Swagger specification—by default, a document named `swagger.json`. It's generated by the Swagger tool chain (or third-party implementations of it) based on your service. It describes the capabilities of your API and how to access it with HTTP. It drives the Swagger UI and is used by the tool chain to enable discovery and client code generation. Here's an example of a Swagger specification, reduced for brevity:

```
{
    "swagger": "2.0",
    "info": {
        "version": "v1",
        "title": "API V1"
    },
    "basePath": "/",
    "paths": {
        "/api/Todo": {
            "get": {
                "tags": [
                    "Todo"
                ],
                "operationId": "ApiTodoGet",
                "consumes": [],
                "produces": [
                    "text/plain",
                    "application/json",
                    "text/json"
                ],
                "responses": {
                    "200": {
                        "description": "Success",
                        "schema": {
                            "type": "array",
                            "items": {
                                "$ref": "#/definitions/TodoItem"
                            }
                        }
                    }
                }
            },
            "post": {
                ...
            }
        },
        "/api/Todo/{id)": {
            "get": {
                ...
            },
            "put": {
                ...
            },
            "delete": {
                ...
            },
            "definitions": {
                "TodoItem": {
                    "type": "object",
                    "properties": {
                        "id": {
                            "format": "int64",
                            "type": "integer"
                        },
                        "name": {
                            "type": "string"
                        },
                        "isComplete": {
                            "default": false,
                            "type": "boolean"
                        }
                    }
                }
            }
        },
        "securityDefinitions": {}
    }
}
```

# Swagger UI

Swagger UI offers a web-based UI that provides information about the service, using the generated Swagger specification. Both Swashbuckle and NSwag include an embedded version of Swagger UI, so that it can be hosted in your ASP.NET Core app using a middleware registration call. The web UI looks like this:

The screenshot shows the Swagger UI interface for a Todo API. At the top, there's a green header bar with the title "swagger" and a URL input field containing "http://localhost:60201/swagger/v1/swagger.json". A dropdown menu "My API V1" is also visible. Below the header, the main content area has a title "Todo" and a "My API" heading. On the right side of the main content, there are three buttons: "Show/Hide", "List Operations", and "Expand Operations". The main content area lists five API operations under the "Todo" category:

- GET /api/Todo** (blue button)
- POST /api/Todo** (green button)
- DELETE /api/Todo/{id}** (red button)
- GET /api/Todo/{id}** (blue button)
- PUT /api/Todo/{id}** (orange button)

At the bottom left, there's a note: "[ BASE URL: / , API VERSION: V1 ]".

Each public action method in your controllers can be tested from the UI. Click a method name to expand the section. Add any necessary parameters, and click **Try it out!**.

**GET** /api/Todo

## Response Class (Status 200)

Success

[Model](#) [Example Value](#)

```
[  
  {  
    "id": 0,  
    "name": "string",  
    "isComplete": false  
  }  
]
```

Response Content Type [text/plain](#)[Try it out!](#) [Hide Response](#)

## Curl

```
curl -X GET --header 'Accept: application/json' 'http://localhost:60201/api/Todo'
```

## Request URL

<http://localhost:60201/api/Todo>

## Response Body

```
[  
  {  
    "id": 1,  
    "name": "Item1",  
    "isComplete": false  
  }  
]
```

## Response Code

200

## Response Headers

```
{  
  "date": "Thu, 31 Aug 2017 17:29:04 GMT",  
  "server": "Kestrel",  
  "transfer-encoding": "chunked",  
  "content-type": "application/json; charset=utf-8"  
}
```

**NOTE**

The Swagger UI version used for the screenshots is version 2. For a version 3 example, see [Petstore example](#).

## Next steps

- [Get started with NSwag](#)

# Get started with NSwag and ASP.NET Core

6/29/2018 • 6 minutes to read • [Edit Online](#)

By [Christoph Nienaber](#) and [Rico Suter](#)

[View or download sample code](#) ([how to download](#))

[View or download sample code](#) ([how to download](#))

Using [NSwag](#) with ASP.NET Core middleware requires the [NSwag.AspNetCore](#) NuGet package. The package consists of a Swagger generator, Swagger UI (v2 and v3), and [ReDoc UI](#).

It's highly recommended to make use of NSwag's code generation capabilities. Choose one of the following options for code generation:

- Use [NSwagStudio](#), a Windows desktop app for generating client code in C# and TypeScript for your API.
- Use the [NSwag.CodeGeneration.CSharp](#) or [NSwag.CodeGeneration.TypeScript](#) NuGet packages to do code generation inside your project.
- Use NSwag from the [command line](#).
- Use the [NSwag.MSBuild](#) NuGet package.

## Features

The main reason to use NSwag is the ability to not only introduce the Swagger UI and Swagger generator, but to make use of the flexible code generation capabilities. You don't need an existing API—you can use third-party APIs that incorporate Swagger and let NSwag generate a client implementation. Either way, the development cycle is expedited and you can more easily adapt to API changes.

## Package installation

The NSwag NuGet package can be added with the following approaches:

- [Visual Studio](#)
- [Visual Studio for Mac](#)
- [Visual Studio Code](#)
- [.NET Core CLI](#)
- From the **Package Manager Console** window:
  - Go to **View > Other Windows > Package Manager Console**
  - Navigate to the directory in which the *TodoApi.csproj* file exists
  - Execute the following command:

```
Install-Package NSwag.AspNetCore
```

- From the **Manage NuGet Packages** dialog:
  - Right-click the project in **Solution Explorer > Manage NuGet Packages**
  - Set the **Package source** to "nuget.org"
  - Enter "NSwag.AspNetCore" in the search box

- Select the "NSwag.AspNetCore" package from the **Browse** tab and click **Install**

## Add and configure Swagger middleware

Import the following namespaces in the `Startup` class:

```
using NJsonSchema;
using NSwag.AspNetCore;
using System.Reflection;
```

In the `Startup.Configure` method, enable the middleware for serving the generated Swagger specification and the Swagger UI:

```
public void Configure(IApplicationBuilder app)
{
    app.UseStaticFiles();

    // Enable the Swagger UI middleware and the Swagger generator
    app.UseSwaggerUi(typeof(Startup).GetTypeInfo().Assembly, settings =>
    {
        settings.GeneratorSettings.DefaultPropertyNameHandling =
            PropertyNameHandling.CamelCase;
    });

    app.UseMvc();
}
```

Launch the app. Navigate to `http://localhost:<port>/swagger` to view the Swagger UI. Navigate to `http://localhost:<port>/swagger/v1/swagger.json` to view the Swagger specification.

## Code generation

### Via NSwagStudio

- Install NSwagStudio from the official [GitHub repository](#).
- Launch NSwagStudio. Enter the `swagger.json` file URL in the **Swagger Specification URL** textbox, and click the **Create local Copy** button.
- Select the **CSharp Client** client output type. Other options include **TypeScript Client** and **CSharp Web API Controller**. Using a Web API Controller is basically a reverse generation. It uses a specification of a service to rebuild the service.
- Click the **Generate Outputs** button. A complete C# client implementation of the `TodoApi.NSwag` project is produced. Click the **CSharp Client** tab of the **Outputs** section to see the generated client code:

```

//-----
// <auto-generated>
//   Generated using the NSwag toolchain v11.17.3.0 (NJsonSchema v9.10.46.0 (Newtonsoft.Json v9.0.0.0))
//   (http://NSwag.org)
// </auto-generated>
//-----

namespace MyNamespace
{
    #pragma warning disable // Disable all warnings

    [System.CodeDom.Compiler.GeneratedCode("NSwag",
        "11.17.3.0 (NJsonSchema v9.10.46.0 (Newtonsoft.Json v9.0.0.0))")]
    public partial class TodoClient
    {
        private string _baseUrl = "http://localhost:50499";
        private System.Lazy<Newtonsoft.Json.JsonSerializerSettings> _settings;

        public TodoClient()
        {
            _settings = new System.Lazy<Newtonsoft.Json.JsonSerializerSettings>(() =>
            {
                var settings = new Newtonsoft.Json.JsonSerializerSettings();
                UpdateJsonSerializerSettings(settings);
                return settings;
            });
        }

        public string BaseUrl
        {
            get { return _baseUrl; }
            set { _baseUrl = value; }
        }

        // code omitted for brevity
    }
}

```

#### TIP

The C# client code is generated based on settings defined in the **Settings** tab of the **CSharp Client** tab. Modify the settings to perform tasks such as default namespace renaming and synchronous method generation.

- Copy the generated C# code into a file in a client project (for example, a [Xamarin.Forms](#) app).
- Start consuming the web API:

```

var todoClient = new TodoClient();

// Gets all to-dos from the API
var allTodos = await todoClient.GetAllAsync();

// Create a new TodoItem, and save it in the API
var createdTodo = await todoClient.CreateAsync(new TodoItem());

// Get a single to-do by ID
var foundTodo = await todoClient.GetByIdAsync(1);

```

#### NOTE

You can inject a base URL and/or a HTTP client into the API client. The best practice is to always [reuse the HttpClient](#).

## Other ways to generate client code

You can generate the client code in other ways, more suited to your workflow:

- [MSBuild](#)
- [In code](#)
- [T4 templates](#)

## Customize

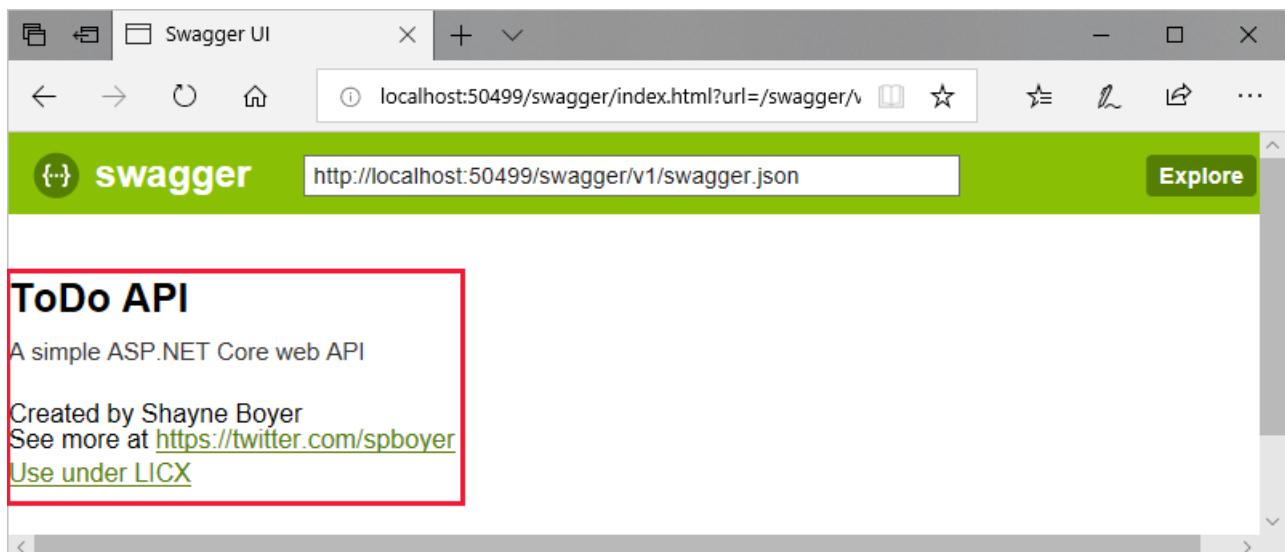

Swagger provides options for documenting the object model to ease consumption of the web API.

### API info and description

In the `Startup.Configure` method, a configuration action passed to the `UseSwagger` method adds information such as the author, license, and description:

```
// Register the Swagger generator
app.UseSwagger(typeof(Startup).Assembly, settings =>
{
    settings.PostProcess = document =>
    {
        document.Info.Version = "v1";
        document.Info.Title = "ToDo API";
        document.Info.Description = "A simple ASP.NET Core web API";
        document.Info.TermsOfService = "None";
        document.Info.Contact = new NSwag.SwaggerContact
        {
            Name = "Shayne Boyer",
            Email = string.Empty,
            Url = "https://twitter.com/spboyer"
        };
        document.Info.License = new NSwag.SwaggerLicense
        {
            Name = "Use under LICX",
            Url = "https://example.com/license"
        };
    };
});
```

The Swagger UI displays the version's information:

## XML comments

XML comments are enabled with the following approaches:

- [Visual Studio](#)
- [Visual Studio for Mac](#)
- [Visual Studio Code](#)
- Right-click the project in **Solution Explorer** and select **Edit <project\_name>.csproj**.
- Manually add the highlighted lines to the .csproj file:

```
<PropertyGroup>
  <GenerateDocumentationFile>true</GenerateDocumentationFile>
  <NoWarn>$(NoWarn);1591</NoWarn>
</PropertyGroup>
```

- Right-click the project in **Solution Explorer** and select **Properties**
- Check the **XML documentation file** box under the **Output** section of the **Build** tab

## Data annotations

NSwag uses [Reflection](#), and the recommended return type for web API actions is [IActionResult](#). Consequently, NSwag can't infer what your action is doing and what it returns. Consider the following example:

```
[HttpPost]
public IActionResult Create([FromBody] TodoItem item)
{
    if (item == null)
    {
        return BadRequest();
    }

    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}
```

The preceding action returns `IActionResult`, but inside the action it's returning either `CreatedAtRoute` or `BadRequest`. Data annotations are used to tell clients which HTTP status codes this action is known to return. Decorate the action with the following attributes:

```
[ProducesResponseType(typeof(TodoItem), 201)] // Created
[ProducesResponseType(400)] // BadRequest
```

NSwag uses [Reflection](#), and the recommended return type for web API actions is [ActionResult<T>](#). Consequently, NSwag can only infer the return type defined by `T`. Other possible return types in the action cannot be inferred. Consider the following example:

```
[HttpPost]
public ActionResult<TodoItem> Create(TodoItem item)
{
    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}
```

The preceding action returns `ActionResult<T>`, but inside the action it's returning either `CreatedAtRoute`. Since the controller is decorated with the [\[ApiController\]](#) attribute, a `BadRequest` response is possible too. See [Automatic HTTP 400 responses](#) for more info. Data annotations are used to tell clients which HTTP status codes this action is

known to return. Decorate the action with the following attributes:

```
[ProducesResponseType(201)]      // Created  
[ProducesResponseType(400)]      // BadRequest
```

The Swagger generator can now accurately describe this action, and generated clients know what they receive when calling the endpoint. Decorating all actions with these attributes is highly recommended. For guidelines on what HTTP responses your API actions should return, see the [RFC 7231 specification](#).

# Get started with Swashbuckle and ASP.NET Core

6/29/2018 • 11 minutes to read • [Edit Online](#)

By [Shayne Boyer](#) and [Scott Addie](#)

[View or download sample code](#) ([how to download](#))

There are three main components to Swashbuckle:

- [Swashbuckle.AspNetCore.Swagger](#): a Swagger object model and middleware to expose `SwaggerDocument` objects as JSON endpoints.
- [Swashbuckle.AspNetCore.SwaggerGen](#): a Swagger generator that builds `SwaggerDocument` objects directly from your routes, controllers, and models. It's typically combined with the Swagger endpoint middleware to automatically expose Swagger JSON.
- [Swashbuckle.AspNetCore.SwaggerUI](#): an embedded version of the Swagger UI tool. It interprets Swagger JSON to build a rich, customizable experience for describing the Web API functionality. It includes built-in test harnesses for the public methods.

## Package installation

Swashbuckle can be added with the following approaches:

- [Visual Studio](#)
- [Visual Studio for Mac](#)
- [Visual Studio Code](#)
- [.NET Core CLI](#)
- From the **Package Manager Console** window:
  - Go to **View > Other Windows > Package Manager Console**
  - Navigate to the directory in which the `TodoApi.csproj` file exists
  - Execute the following command:

```
Install-Package Swashbuckle.AspNetCore
```

- From the **Manage NuGet Packages** dialog:
  - Right-click the project in **Solution Explorer > Manage NuGet Packages**
  - Set the **Package source** to "nuget.org"
  - Enter "Swashbuckle.AspNetCore" in the search box
  - Select the "Swashbuckle.AspNetCore" package from the **Browse** tab and click **Install**

## Add and configure Swagger middleware

Add the Swagger generator to the services collection in the `Startup.ConfigureServices` method:

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddDbContext<TodoContext>(opt =>
        opt.UseInMemoryDatabase("TodoList"));
    services.AddMvc();

    // Register the Swagger generator, defining 1 or more Swagger documents
    services.AddSwaggerGen(c =>
    {
        c.SwaggerDoc("v1", new Info { Title = "My API", Version = "v1" });
    });
}
```

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddDbContext<TodoContext>(opt =>
        opt.UseInMemoryDatabase("TodoList"));
    services.AddMvc()
        .SetCompatibilityVersion(CompatibilityVersion.Version_2_1);

    // Register the Swagger generator, defining 1 or more Swagger documents
    services.AddSwaggerGen(c =>
    {
        c.SwaggerDoc("v1", new Info { Title = "My API", Version = "v1" });
    });
}
```

Import the following namespace to use the `Info` class:

```
using Swashbuckle.AspNetCore.Swagger;
```

In the `Startup.Configure` method, enable the middleware for serving the generated JSON document and the Swagger UI:

```
public void Configure(IApplicationBuilder app)
{
    // Enable middleware to serve generated Swagger as a JSON endpoint.
    app.UseSwagger();

    // Enable middleware to serve swagger-ui (HTML, JS, CSS, etc.),
    // specifying the Swagger JSON endpoint.
    app.UseSwaggerUI(c =>
    {
        c.SwaggerEndpoint("/swagger/v1/swagger.json", "My API V1");
    });

    app.UseMvc();
}
```

Launch the app, and navigate to `http://localhost:<port>/swagger/v1/swagger.json`. The generated document describing the endpoints appears as shown in [Swagger specification \(swagger.json\)](#).

The Swagger UI can be found at `http://localhost:<port>/swagger`. Explore the API via Swagger UI and incorporate it in other programs.

## TIP

To serve the Swagger UI at the app's root (`http://localhost:<port>/`), set the `RoutePrefix` property to an empty string:

```
app.UseSwaggerUI(c =>
{
    c.SwaggerEndpoint("/swagger/v1/swagger.json", "My API V1");
    c.RoutePrefix = string.Empty;
});
```

## Customize and extend

Swagger provides options for documenting the object model and customizing the UI to match your theme.

### API info and description

The configuration action passed to the `AddSwaggerGen` method adds information such as the author, license, and description:

```
// Register the Swagger generator, defining 1 or more Swagger documents
services.AddSwaggerGen(c =>
{
    c.SwaggerDoc("v1", new Info
    {
        Version = "v1",
        Title = "ToDo API",
        Description = "A simple example ASP.NET Core Web API",
        TermsOfService = "None",
        Contact = new Contact
        {
            Name = "Shayne Boyer",
            Email = string.Empty,
            Url = "https://twitter.com/spboyer"
        },
        License = new License
        {
            Name = "Use under LICX",
            Url = "https://example.com/license"
        }
    });
});
```

The Swagger UI displays the version's information:

The screenshot shows the Swagger UI interface for a 'ToDo API' at version v1. The main title 'ToDo API' is displayed with a red border around it. Below the title, there is a link to '/swagger/v1/swagger.json'. Underneath the link, the text 'A simple example ASP.NET Core Web API' is shown. At the bottom of this section, there are three links: 'Terms of service', 'Shayne Boyer - Website', and 'Use under LICX'. The top navigation bar includes tabs for 'Select a spec' (set to 'My API V1') and a dropdown menu.

## XML comments

XML comments can be enabled with the following approaches:

- [Visual Studio](#)
- [Visual Studio for Mac](#)
- [Visual Studio Code](#)
- Right-click the project in **Solution Explorer** and select **Edit <project\_name>.csproj**.
- Manually add the highlighted lines to the `.csproj` file:

```
<PropertyGroup>
  <GenerateDocumentationFile>true</GenerateDocumentationFile>
  <NoWarn>$(NoWarn);1591</NoWarn>
</PropertyGroup>
```

- Right-click the project in **Solution Explorer** and select **Properties**.
- Check the **XML documentation file** box under the **Output** section of the **Build** tab.

Enabling XML comments provides debug information for undocumented public types and members.

Undocumented types and members are indicated by the warning message. For example, the following message indicates a violation of warning code 1591:

```
warning CS1591: Missing XML comment for publicly visible type or member 'TodoController.GetAll()'
```

Suppress warnings by defining a semicolon-delimited list of warning codes to ignore in the `.csproj` file. Appending the warning codes to `$(NoWarn);` applies the C# default values too.

```
<PropertyGroup>
  <GenerateDocumentationFile>true</GenerateDocumentationFile>
  <NoWarn>$(NoWarn);1591</NoWarn>
</PropertyGroup>
```

```
<PropertyGroup>
  <DocumentationFile>bin\$(Configuration)\$(TargetFramework)\$(AssemblyName).xml</DocumentationFile>
  <NoWarn>$(NoWarn);1591</NoWarn>
</PropertyGroup>
```

Configure Swagger to use the generated XML file. For Linux or non-Windows operating systems, file names and paths can be case-sensitive. For example, a *TodoApi.XML* file is valid on Windows but not CentOS.

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddDbContext<TodoContext>(opt =>
        opt.UseInMemoryDatabase("TodoList"));
    services.AddMvc()
        .SetCompatibilityVersion(CompatibilityVersion.Version_2_1);

    // Register the Swagger generator, defining 1 or more Swagger documents
    services.AddSwaggerGen(c =>
    {
        c.SwaggerDoc("v1", new Info
        {
            Version = "v1",
            Title = "ToDo API",
            Description = "A simple example ASP.NET Core Web API",
            TermsOfService = "None",
            Contact = new Contact
            {
                Name = "Shayne Boyer",
                Email = string.Empty,
                Url = "https://twitter.com/spboyer"
            },
            License = new License
            {
                Name = "Use under LICX",
                Url = "https://example.com/license"
            }
        });
    });

    // Set the comments path for the Swagger JSON and UI.
    var xmlFile = $"{Assembly.GetExecutingAssembly().GetName().Name}.xml";
    var xmlPath = Path.Combine(AppContext.BaseDirectory, xmlFile);
    c.IncludeXmlComments(xmlPath);
});
```

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddDbContext<TodoContext>(opt =>
        opt.UseInMemoryDatabase("TodoList"));
    services.AddMvc();

    // Register the Swagger generator, defining 1 or more Swagger documents
    services.AddSwaggerGen(c =>
    {
        c.SwaggerDoc("v1", new Info
        {
            Version = "v1",
            Title = "ToDo API",
            Description = "A simple example ASP.NET Core Web API",
            TermsOfService = "None",
            Contact = new Contact
            {
                Name = "Shayne Boyer",
                Email = string.Empty,
                Url = "https://twitter.com/spboyer"
            },
            License = new License
            {
                Name = "Use under LICX",
                Url = "https://example.com/license"
            }
        });
    });

    // Set the comments path for the Swagger JSON and UI.
    var xmlFile = $"{Assembly.GetExecutingAssembly().GetName().Name}.xml";
    var xmlPath = Path.Combine(AppContext.BaseDirectory, xmlFile);
    c.IncludeXmlComments(xmlPath);
});

}
```

```

public void ConfigureServices(IServiceCollection services)
{
    services.AddDbContext<TodoContext>(opt =>
        opt.UseInMemoryDatabase("TodoList"));
    services.AddMvc();

    // Register the Swagger generator, defining 1 or more Swagger documents
    services.AddSwaggerGen(c =>
    {
        c.SwaggerDoc("v1", new Info
        {
            Version = "v1",
            Title = "ToDo API",
            Description = "A simple example ASP.NET Core Web API",
            TermsOfService = "None",
            Contact = new Contact
            {
                Name = "Shayne Boyer",
                Email = string.Empty,
                Url = "https://twitter.com/spboyer"
            },
            License = new License
            {
                Name = "Use under LICX",
                Url = "https://example.com/license"
            }
        });
    });

    // Set the comments path for the Swagger JSON and UI.
    var xmlFile = $"{Assembly.GetEntryAssembly().GetName().Name}.xml";
    var xmlPath = Path.Combine(AppContext.BaseDirectory, xmlFile);
    c.IncludeXmlComments(xmlPath);
});
}

```

In the preceding code, [Reflection](#) is used to build an XML file name matching that of the Web API project. The [AppContext.BaseDirectory](#) property is used to construct a path to the XML file.

Adding triple-slash comments to an action enhances the Swagger UI by adding the description to the section header. Add a [`<summary>`](#) element above the [`Delete`](#) action:

```

/// <summary>
/// Deletes a specific TodoItem.
/// </summary>
/// <param name="id"></param>
[HttpDelete("{id}")]
public IActionResult Delete(long id)
{
    var todo = _context.TodoItems.Find(id);

    if (todo == null)
    {
        return NotFound();
    }

    _context.TodoItems.Remove(todo);
    _context.SaveChanges();

    return NoContent();
}

```

The Swagger UI displays the inner text of the preceding code's [`<summary>`](#) element:

The screenshot shows the Swagger UI interface for a DELETE operation. At the top left is a red button labeled "DELETE". To its right is the endpoint path "/api/Todo/{id}" in a blue box, with a description "Deletes a specific TodoItem." below it. In the top right corner is a "Try it out" button. Below the header, there's a section titled "Parameters" with a table. The first parameter is "id \* required" (type: integer, path). There's also a "Responses" section with a table for the 200 status code, which has a "Success" description. The "Code" column lists the HTTP status code, and the "Description" column lists the response message.

Name	Description
<b>id</b> * required integer (path)	

Responses	Response content type
	application/json

Code	Description
200	<i>Success</i>

The UI is driven by the generated JSON schema:

```

"delete": {
    "tags": [
        "Todo"
    ],
    "summary": "Deletes a specific TodoItem.",
    "operationId": "ApiTodoByIdDelete",
    "consumes": [],
    "produces": [],
    "parameters": [
        {
            "name": "id",
            "in": "path",
            "description": "",
            "required": true,
            "type": "integer",
            "format": "int64"
        }
    ],
    "responses": {
        "200": {
            "description": "Success"
        }
    }
}

```

Add a `<remarks>` element to the `Create` action method documentation. It supplements information specified in the `<summary>` element and provides a more robust Swagger UI. The `<remarks>` element content can consist of text, JSON, or XML.

```

/// <summary>
/// Creates a TodoItem.
/// </summary>
/// <remarks>
/// Sample request:
///
///     POST /Todo
/// {
///     "id": 1,
///     "name": "Item1",
///     "isComplete": true
/// }
///
/// </remarks>
/// <param name="item"></param>
/// <returns>A newly created TodoItem</returns>
/// <response code="201">Returns the newly created item</response>
/// <response code="400">If the item is null</response>
[HttpPost]
[ProducesResponseType(typeof(TodoItem), 201)]
[ProducesResponseType(400)]
public IActionResult Create([FromBody] TodoItem item)
{
    if (item == null)
    {
        return BadRequest();
    }

    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}

```

```

/// <summary>
/// Creates a TodoItem.
/// </summary>
/// <remarks>
/// Sample request:
///
///     POST /Todo
/// {
///     "id": 1,
///     "name": "Item1",
///     "isComplete": true
/// }
///
/// </remarks>
/// <param name="item"></param>
/// <returns>A newly created TodoItem</returns>
/// <response code="201">Returns the newly created item</response>
/// <response code="400">If the item is null</response>
[HttpPost]
[ProducesResponseType(201)]
[ProducesResponseType(400)]
public ActionResult<TodoItem> Create(TodoItem item)
{
    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}

```

Notice the UI enhancements with these additional comments:

**POST**

/api/Todo Creates a TodoItem.

Sample request:

```
POST /Todo
{
    "id": 1,
    "name": "Item1",
    "isComplete": true
}
```

## Data annotations

Decorate the model with attributes, found in the [System.ComponentModel.DataAnnotations](#) namespace, to help drive the Swagger UI components.

Add the `[Required]` attribute to the `Name` property of the `TodoItem` class:

```
using System.ComponentModel;
using System.ComponentModel.DataAnnotations;

namespace TodoApi.Models
{
    public class TodoItem
    {
        public long Id { get; set; }

        [Required]
        public string Name { get; set; }

        [DefaultValue(false)]
        public bool IsComplete { get; set; }
    }
}
```

The presence of this attribute changes the UI behavior and alters the underlying JSON schema:

```
"definitions": {
    "TodoItem": {
        "required": [
            "name"
        ],
        "type": "object",
        "properties": {
            "id": {
                "format": "int64",
                "type": "integer"
            },
            "name": {
                "type": "string"
            },
            "isComplete": {
                "default": false,
                "type": "boolean"
            }
        }
    }
},
```

Add the `[Produces("application/json")]` attribute to the API controller. Its purpose is to declare that the controller's actions support a response content type of *application/json*:

```
[Produces("application/json")]
[Route("api/[controller]")]
public class TodoController : ControllerBase
{
    private readonly TodoContext _context;
```

```
[Produces("application/json")]
[Route("api/[controller]")]
[ApiController]
public class TodoController : ControllerBase
{
    private readonly TodoContext _context;
```

The **Response Content Type** drop-down selects this content type as the default for the controller's GET actions:

The screenshot shows the Swagger UI interface for a `GET /api/Todo` endpoint. The top navigation bar has a blue button for `GET` and the URL `/api/Todo`. Below it, there's a **Parameters** section with a note "No parameters". On the right, there's a **Try it out** button. In the bottom right corner of the main content area, there's a **Responses** section. Within this section, there's a **Response content type** dropdown menu. The menu is open, showing the value `application/json`, which is highlighted with a red rectangular border.

As the usage of data annotations in the Web API increases, the UI and API help pages become more descriptive and useful.

### Describe response types

Consuming developers are most concerned with what's returned—specifically response types and error codes (if not standard). The response types and error codes are denoted in the XML comments and data annotations.

The `Create` action returns an HTTP 201 status code on success. An HTTP 400 status code is returned when the posted request body is null. Without proper documentation in the Swagger UI, the consumer lacks knowledge of these expected outcomes. Fix that problem by adding the highlighted lines in the following example:

```

/// <summary>
/// Creates a TodoItem.
/// </summary>
/// <remarks>
/// Sample request:
///
///     POST /Todo
///     {
///         "id": 1,
///         "name": "Item1",
///         "isComplete": true
///     }
///
/// </remarks>
/// <param name="item"></param>
/// <returns>A newly created TodoItem</returns>
/// <response code="201">Returns the newly created item</response>
/// <response code="400">If the item is null</response>
[HttpPost]
[ProducesResponseType(typeof(TodoItem), 201)]
[ProducesResponseType(400)]
public IActionResult Create([FromBody] TodoItem item)
{
    if (item == null)
    {
        return BadRequest();
    }

    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}

```

```

/// <summary>
/// Creates a TodoItem.
/// </summary>
/// <remarks>
/// Sample request:
///
///     POST /Todo
///     {
///         "id": 1,
///         "name": "Item1",
///         "isComplete": true
///     }
///
/// </remarks>
/// <param name="item"></param>
/// <returns>A newly created TodoItem</returns>
/// <response code="201">Returns the newly created item</response>
/// <response code="400">If the item is null</response>
[HttpPost]
[ProducesResponseType(201)]
[ProducesResponseType(400)]
public ActionResult<TodoItem> Create(TodoItem item)
{
    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}

```

The Swagger UI now clearly documents the expected HTTP response codes:

The screenshot shows the 'Responses' section of the Swagger UI. At the top, it says 'Response content type application/json'. Below that, there's a table with two columns: 'Code' and 'Description'. The first row shows '201' and 'Returns the newly created item'. A red box highlights this row. Below it, there's a 'Example Value' button and a 'Model' link. The model is shown as a JSON object: { "id": 0, "name": "string", "isComplete": false }. The second row shows '400' and 'If the item is null'.

## Customize the UI

The stock UI is both functional and presentable. However, API documentation pages should represent your brand or theme. Branding the Swashbuckle components requires adding the resources to serve static files and building the folder structure to host those files.

If targeting .NET Framework or .NET Core 1.x, add the [Microsoft.AspNetCore.StaticFiles](#) NuGet package to the project:

```
<PackageReference Include="Microsoft.AspNetCore.StaticFiles" Version="2.0.0" />
```

The preceding NuGet package is already installed if targeting .NET Core 2.x and using the [metapackage](#).

Enable the static files middleware:

```
public void Configure(IApplicationBuilder app)
{
    app.UseStaticFiles();

    // Enable middleware to serve generated Swagger as a JSON endpoint.
    app.UseSwagger();

    // Enable middleware to serve swagger-ui (HTML, JS, CSS, etc.),
    // specifying the Swagger JSON endpoint.
    app.UseSwaggerUI(c =>
    {
        c.SwaggerEndpoint("/swagger/v1/swagger.json", "My API V1");
    });

    app.UseMvc();
}
```

Acquire the contents of the *dist* folder from the [Swagger UI GitHub repository](#). This folder contains the necessary assets for the Swagger UI page.

Create a *wwwroot/swagger/ui* folder, and copy into it the contents of the *dist* folder.

Create a *custom.css* file, in *wwwroot/swagger/ui*, with the following CSS to customize the page header:

```
.swagger-ui .topbar {  
    background-color: #000;  
    border-bottom: 3px solid #547f00;  
}
```

Reference *custom.css* in the *index.html* file, after any other CSS files:

```
<link href="https://fonts.googleapis.com/css?  
family=Open+Sans:400,700|Source+Code+Pro:300,600|Titillium+Web:400,600,700" rel="stylesheet">  
<link rel="stylesheet" type="text/css" href="/swagger-ui.css">  
<link rel="stylesheet" type="text/css" href="custom.css">
```

Browse to the *index.html* page at `http://localhost:<port>/swagger/ui/index.html`. Enter `http://localhost:<port>/swagger/v1/swagger.json` in the header's textbox, and click the **Explore** button. The resulting page looks as follows:

The screenshot shows the Swagger UI interface for a Todo API. At the top, there is a navigation bar with the Swagger logo, the URL `http://localhost:49253/swagger/v1/swagger.json`, and an **Explore** button. Below the navigation bar, the title "ToDo API" is displayed with a "v1" badge. A link to the API documentation at `http://localhost:49253/swagger/v1/swagger.json` is provided. Below the title, there are links for "Terms of service", "Shayne Boyer - Website", and "Use under LICX".

The main content area is titled "Todo". It lists five API endpoints:

- GET** `/api/Todo`
- POST** `/api/Todo` Creates a Todolitem.
- GET** `/api/Todo/{id}`
- PUT** `/api/Todo/{id}`
- DELETE** `/api/Todo/{id}` Deletes a specific Todolitem.

Below the endpoints, there is a section titled "Models" which contains a link to "Todolitem".

There's much more you can do with the page. See the full capabilities for the UI resources at the [Swagger UI GitHub repository](#).

# Razor Pages with Entity Framework Core in ASP.NET Core - Tutorial 1 of 8

7/10/2018 • 15 minutes to read • [Edit Online](#)

The ASP.NET Core 2.0 version of this tutorial can be found in [this PDF file](#).

The ASP.NET Core 2.1 version of this tutorial has many improvements over the 2.0 version.

By [Tom Dykstra](#) and [Rick Anderson](#)

The Contoso University sample web app demonstrates how to create an ASP.NET Core Razor Pages app using Entity Framework (EF) Core.

The sample app is a web site for a fictional Contoso University. It includes functionality such as student admission, course creation, and instructor assignments. This page is the first in a series of tutorials that explain how to build the Contoso University sample app.

[Download or view the completed app.](#) [Download instructions.](#)

## Prerequisites

- [Visual Studio](#)
- [.NET Core CLI](#)

[Visual Studio 2017 version 15.7.3 or later](#) with the following workloads:

- **ASP.NET and web development**
- **.NET Core cross-platform development**

[.NET Core 2.1 SDK or later](#)

Familiarity with [Razor Pages](#). New programmers should complete [Get started with Razor Pages](#) before starting this series.

## Troubleshooting

If you run into a problem you can't resolve, you can generally find the solution by comparing your code to the [completed project](#). A good way to get help is by posting a question to [StackOverflow.com](#) for [ASP.NET Core](#) or [EF Core](#).

## The Contoso University web app

The app built in these tutorials is a basic university web site.

Users can view and update student, course, and instructor information. Here are a few of the screens created in the tutorial.

The screenshot shows a web browser window titled "Index - Contoso University". The address bar displays "localhost:1234/Students". The page header "Contoso University" has a three-line menu icon. The main content area is titled "Index" with a "Create New" link. A search bar with placeholder "Find by name:" and a "Search" button is present. Below is a table with columns "Last Name", "First Name", and "Enrollment Date". Three rows of student data are listed:

Last Name	First Name	Enrollment Date	
Smith	Joe	2017-10-31	Edit   Details   Delete
Alexander	Carson	2010-09-01	Edit   Details   Delete
Alonso	Meredith	2012-09-01	Edit   Details   Delete

Navigation buttons "Previous" and "Next" are at the bottom, along with a copyright notice: "© 2017 - Contoso University".

The screenshot shows a web browser window titled "Edit - Contoso University". The address bar displays "localhost:1234/Students/Edit/1". The page header "Contoso University" has a three-line menu icon. The main content area is titled "Edit" with a "Student" subtitle. It contains three input fields: "Last Name" (Alexander), "First Name" (Carson), and "Enrollment Date" (09/01/2010). A "Save" button is below the date field. Navigation links "Back to List" and "© 2017 - Contoso University" are at the bottom.

The UI style of this site is close to what's generated by the built-in templates. The tutorial focus is on EF Core with

Razor Pages, not the UI.

## Create the ContosoUniversity Razor Pages web app

- [Visual Studio](#)
  - [.NET Core CLI](#)
- From the Visual Studio **File** menu, select **New > Project**.
  - Create a new ASP.NET Core Web Application. Name the project **ContosoUniversity**. It's important to name the project *ContosoUniversity* so the namespaces match when code is copy/pasted.
  - Select **ASP.NET Core 2.1** in the dropdown, and then select **Web Application**.

For images of the preceding steps, see [Create a Razor web app](#). Run the app.

## Set up the site style

A few changes set up the site menu, layout, and home page. Update *Pages/Shared/\_Layout.cshtml* with the following changes:

- Change each occurrence of "ContosoUniversity" to "Contoso University". There are three occurrences.
- Add menu entries for **Students**, **Courses**, **Instructors**, and **Departments**, and delete the **Contact** menu entry.

The changes are highlighted. (All the markup is *not* displayed.)

```

<!DOCTYPE html>
<html>
<head>
    <meta charset="utf-8" />
    <meta name="viewport" content="width=device-width, initial-scale=1.0" />
    <title>@ViewData["Title"] : Contoso University</title>

    <environment include="Development">
        <link rel="stylesheet" href="~/lib/bootstrap/dist/css/bootstrap.css" />
        <link rel="stylesheet" href("~/css/site.css" />
    </environment>
    <environment exclude="Development">
        <link rel="stylesheet" href="https://ajax.aspnetcdn.com/ajax/bootstrap/3.3.7/css/bootstrap.min.css"
              asp-fallback-href="~/lib/bootstrap/dist/css/bootstrap.min.css"
              asp-fallback-test-class="sr-only" asp-fallback-test-property="position" asp-fallback-test-
              value="absolute" />
        <link rel="stylesheet" href "~/css/site.min.css" asp-append-version="true" />
    </environment>
</head>
<body>
    <nav class="navbar navbar-inverse navbar-fixed-top">
        <div class="container">
            <div class="navbar-header">
                <button type="button" class="navbar-toggle" data-toggle="collapse" data-target=".navbar-
collapse">
                    <span class="sr-only">Toggle navigation</span>
                    <span class="icon-bar"></span>
                    <span class="icon-bar"></span>
                    <span class="icon-bar"></span>
                </button>
                <a asp-page="/Index" class="navbar-brand">Contoso University</a>
            </div>
            <div class="navbar-collapse collapse">
                <ul class="nav navbar-nav">
                    <li><a asp-page="/Index">Home</a></li>
                    <li><a asp-page="/About">About</a></li>
                    <li><a asp-page="/Students/Index">Students</a></li>
                    <li><a asp-page="/Courses/Index">Courses</a></li>
                    <li><a asp-page="/Instructors/Index">Instructors</a></li>
                    <li><a asp-page="/Departments/Index">Departments</a></li>
                </ul>
            </div>
        </div>
    </nav>

    <partial name="_CookieConsentPartial" />

    <div class="container body-content">
        @RenderBody()
        <hr />
        <footer>
            <p>&copy; 2018 : Contoso University</p>
        </footer>
    </div>

    @*Remaining markup not shown for brevity.*@

```

In *Pages/Index.cshtml*, replace the contents of the file with the following code to replace the text about ASP.NET and MVC with text about this app:

```

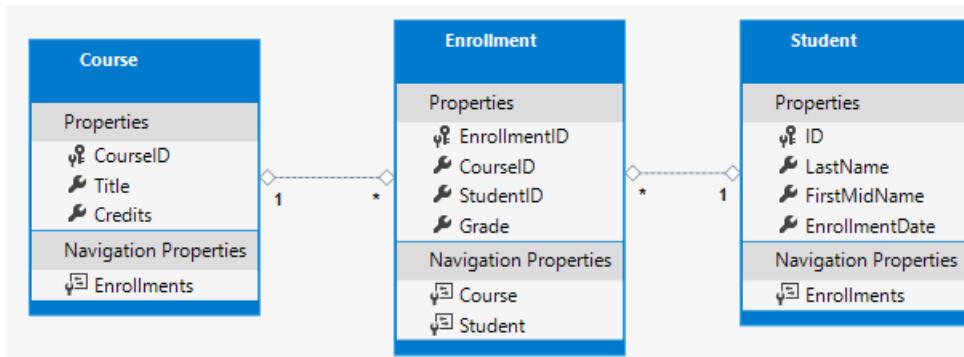

@page
@model IndexModel
 @{
     ViewData["Title"] = "Home page";
 }

<div class="jumbotron">
    <h1>Contoso University</h1>
</div>
<div class="row">
    <div class="col-md-4">
        <h2>Welcome to Contoso University</h2>
        <p>
            Contoso University is a sample application that
            demonstrates how to use Entity Framework Core in an
            ASP.NET Core Razor Pages web app.
        </p>
    </div>
    <div class="col-md-4">
        <h2>Build it from scratch</h2>
        <p>You can build the application by following the steps in a series of tutorials.</p>
        <p>
            <a class="btn btn-default"
                href="https://docs.microsoft.com/aspnet/core/data/ef-rp/intro">
                See the tutorial &raquo;
            </a>
        </p>
    </div>
    <div class="col-md-4">
        <h2>Download it</h2>
        <p>You can download the completed project from GitHub.</p>
        <p>
            <a class="btn btn-default"
                href="https://github.com/aspnet/Docs/tree/master/aspnetcore/data/ef-rp/intro/samples/cu-final">
                See project source code &raquo;
            </a>
        </p>
    </div>
</div>

```

## Create the data model

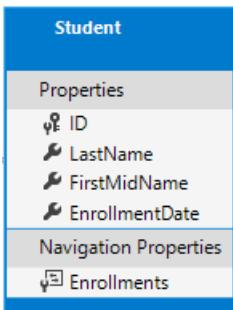

Create entity classes for the Contoso University app. Start with the following three entities:

There's a one-to-many relationship between `Student` and `Enrollment` entities. There's a one-to-many relationship between `Course` and `Enrollment` entities. A student can enroll in any number of courses. A course can have any number of students enrolled in it.

In the following sections, a class for each one of these entities is created.

### The Student entity

Create a *Models* folder. In the *Models* folder, create a class file named *Student.cs* with the following code:

```
using System;
using System.Collections.Generic;

namespace ContosoUniversity.Models
{
    public class Student
    {
        public int ID { get; set; }
        public string LastName { get; set; }
        public string FirstMidName { get; set; }
        public DateTime EnrollmentDate { get; set; }

        public ICollection<Enrollment> Enrollments { get; set; }
    }
}
```

The `ID` property becomes the primary key column of the database (DB) table that corresponds to this class. By default, EF Core interprets a property that's named `ID` or `classnameID` as the primary key. In `classnameID`, `classname` is the name of the class. The alternative automatically recognized primary key is `StudentID` in the preceding example.

The `Enrollments` property is a navigation property. Navigation properties link to other entities that are related to this entity. In this case, the `Enrollments` property of a `Student` entity holds all of the `Enrollment` entities that are related to that `Student`. For example, if a `Student` row in the DB has two related `Enrollment` rows, the `Enrollments` navigation property contains those two `Enrollment` entities. A related `Enrollment` row is a row that contains that student's primary key value in the `StudentID` column. For example, suppose the student with `ID=1` has two rows in the `Enrollment` table. The `Enrollment` table has two rows with `StudentID = 1`. `StudentID` is a foreign key in the `Enrollment` table that specifies the student in the `Student` table.

If a navigation property can hold multiple entities, the navigation property must be a list type, such as `ICollection<T>`. `ICollection<T>` can be specified, or a type such as `List<T>` or `HashSet<T>`. When `ICollection<T>` is used, EF Core creates a `HashSet<T>` collection by default. Navigation properties that hold multiple entities come from many-to-many and one-to-many relationships.

## The Enrollment entity

In the *Models* folder, create *Enrollment.cs* with the following code:

```

namespace ContosoUniversity.Models
{
    public enum Grade
    {
        A, B, C, D, F
    }

    public class Enrollment
    {
        public int EnrollmentID { get; set; }
        public int CourseID { get; set; }
        public int StudentID { get; set; }
        public Grade? Grade { get; set; }

        public Course Course { get; set; }
        public Student Student { get; set; }
    }
}

```

The `EnrollmentID` property is the primary key. This entity uses the `classnameID` pattern instead of `ID` like the `Student` entity. Typically developers choose one pattern and use it throughout the data model. In a later tutorial, using ID without classname is shown to make it easier to implement inheritance in the data model.

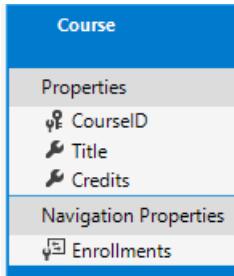

The `Grade` property is an `enum`. The question mark after the `Grade` type declaration indicates that the `Grade` property is nullable. A grade that's null is different from a zero grade -- null means a grade isn't known or hasn't been assigned yet.

The `StudentID` property is a foreign key, and the corresponding navigation property is `Student`. An `Enrollment` entity is associated with one `Student` entity, so the property contains a single `Student` entity. The `Student` entity differs from the `student.Enrollments` navigation property, which contains multiple `Enrollment` entities.

The `CourseID` property is a foreign key, and the corresponding navigation property is `course`. An `Enrollment` entity is associated with one `Course` entity.

EF Core interprets a property as a foreign key if it's named `<navigation property name><primary key property name>`. For example, `StudentID` for the `Student` navigation property, since the `Student` entity's primary key is `ID`. Foreign key properties can also be named `<primary key property name>`. For example, `CourseID` since the `Course` entity's primary key is `CourseID`.

## The Course entity

In the `Models` folder, create `Course.cs` with the following code:

```

using System.Collections.Generic;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Course
    {
        [DatabaseGenerated(DatabaseGeneratedOption.None)]
        public int CourseID { get; set; }
        public string Title { get; set; }
        public int Credits { get; set; }

        public ICollection<Enrollment> Enrollments { get; set; }
    }
}

```

The `Enrollments` property is a navigation property. A `Course` entity can be related to any number of `Enrollment` entities.

The `DatabaseGenerated` attribute allows the app to specify the primary key rather than having the DB generate it.

## Scaffold the student model

In this section, the student model is scaffolded. That is, the scaffolding tool produces pages for Create, Read, Update, and Delete (CRUD) operations for the student model.

- Build the project.
- Create the *Pages/Students* folder.
- [Visual Studio](#)
- [.NET Core CLI](#)
- In **Solution Explorer**, right click on the *Pages/Students* folder > **Add > New Scaffolded Item**.
- In the **Add Scaffold** dialog, select **Razor Pages using Entity Framework (CRUD)** > **ADD**.

Complete the **Add Razor Pages using Entity Framework (CRUD)** dialog:

- In the **Model class** drop-down, select **Student (ContosoUniversity.Models)**.
- In the **Data context class** row, select the + (plus) sign and change the generated name to **ContosoUniversity.Models.SchoolContext**.
- In the **Data context class** drop-down, select **ContosoUniversity.Models.SchoolContext**
- Select **Add**.

## Add Razor Pages using Entity Framework (CRUD)

X

Generates Razor Pages using Entity Framework for; Create, Delete, Details, Edit and List operations for the selected model.

Model class:

Data context class:  - +

Options:

- Create as a partial view
- Reference script libraries
- Use a layout page:

...

(Leave empty if it is set in a Razor \_viewstart file)

Add

Cancel

See [Scaffold the movie model](#) if you have a problem with the preceding step.

The scaffold process created and changed the following files:

### Files created

- Pages/Students Create, Delete, Details, Edit, Index.
- Data/ContosoUniversityContext.cs

### Files updates

- Startup.cs : Changes to this file are detailed the next section.
- appsettings.json : The connection string used to connect to a local database is added.

## Examine the context registered with dependency injection

ASP.NET Core is built with [dependency injection](#). Services (such as the EF Core DB context) are registered with dependency injection during application startup. Components that require these services (such as Razor Pages) are provided these services via constructor parameters. The constructor code that gets a db context instance is shown later in the tutorial.

The scaffolding tool automatically created a DB Context and registered it with the dependency injection container.

Examine the `ConfigureServices` method in `Startup.cs`. The highlighted line was added by the scaffolder:

```
public void ConfigureServices(IServiceCollection services)
{
    services.Configure<CookiePolicyOptions>(options =>
    {
        // This lambda determines whether user consent for
        // non-essential cookies is needed for a given request.
        options.CheckConsentNeeded = context => true;
        options.MinimumSameSitePolicy = SameSiteMode.None;
    });

    services.AddMvc().SetCompatibilityVersion(CompatibilityVersion.Version_2_1);

    services.AddDbContext<SchoolContext>(options =>
        options.UseSqlServer(Configuration.GetConnectionString("SchoolContext")));
}
```

The name of the connection string is passed in to the context by calling a method on a [DbContextOptions](#) object. For local development, the [ASP.NET Core configuration system](#) reads the connection string from the *appsettings.json* file.

## Update main

In *Program.cs*, modify the `Main` method to do the following:

- Get a DB context instance from the dependency injection container.
- Call the [EnsureCreated](#).
- Dispose the context when the `EnsureCreated` method completes.

The following code shows the updated *Program.cs* file.

```

using ContosoUniversity.Models; // SchoolContext
using Microsoft.AspNetCore;
using Microsoft.AspNetCore.Hosting;
using Microsoft.Extensions.DependencyInjection; // CreateScope
using Microsoft.Extensions.Logging;
using System;

namespace ContosoUniversity
{
    public class Program
    {
        public static void Main(string[] args)
        {
            var host = CreateWebHostBuilder(args).Build();

            using (var scope = host.Services.CreateScope())
            {
                var services = scope.ServiceProvider;

                try
                {
                    var context = services.GetRequiredService<SchoolContext>();
                    context.Database.EnsureCreated();
                }
                catch (Exception ex)
                {
                    var logger = services.GetRequiredService<ILogger<Program>>();
                    logger.LogError(ex, "An error occurred creating the DB.");
                }
            }

            host.Run();
        }

        public static IWebHostBuilder CreateWebHostBuilder(string[] args) =>
            WebHost.CreateDefaultBuilder(args)
                .UseStartup<Startup>();
    }
}

```

`EnsureCreated` ensures that the database for the context exists. If it exists, no action is taken. If it does not exist, then the database and all its schema are created. `EnsureCreated` does not use migrations to create the database. A database that is created with `EnsureCreated` cannot be later updated using migrations.

`EnsureCreated` is called on app start, which allows the following work flow:

- Delete the DB.
- Change the DB schema (for example, add an `EmailAddress` field).
- Run the app.
- `EnsureCreated` creates a DB with the `EmailAddress` column.

`EnsureCreated` is convenient early in development when the schema is rapidly evolving. Later in the tutorial the DB is deleted and migrations are used.

## Test the app

Run the app and accept the cookie policy. This app doesn't keep personal information. You can read about the cookie policy at [EU General Data Protection Regulation \(GDPR\) support](#).

- Select the **Students** link and then **Create New**.
- Test the Edit, Details, and Delete links.

## Examine the SchoolContext DB context

The main class that coordinates EF Core functionality for a given data model is the DB context class. The data context is derived from [Microsoft.EntityFrameworkCore.DbContext](#). The data context specifies which entities are included in the data model. In this project, the class is named `SchoolContext`.

Update `SchoolContext.cs` with the following code:

```
using Microsoft.EntityFrameworkCore;

namespace ContosoUniversity.Models
{
    public class SchoolContext : DbContext
    {
        public SchoolContext(DbContextOptions<SchoolContext> options)
            : base(options)
        {
        }

        public DbSet<Student> Student { get; set; }
        public DbSet<Enrollment> Enrollment { get; set; }
        public DbSet<Course> Course { get; set; }
    }
}
```

The highlighted code creates a `DbSet< TEntity >` property for each entity set. In EF Core terminology:

- An entity set typically corresponds to a DB table.
- An entity corresponds to a row in the table.

`DbSet<Enrollment>` and `DbSet<Course>` could be omitted. EF Core includes them implicitly because the `Student` entity references the `Enrollment` entity, and the `Enrollment` entity references the `Course` entity. For this tutorial, keep `DbSet<Enrollment>` and `DbSet<Course>` in the `SchoolContext`.

## SQL Server Express LocalDB

The connection string specifies [SQL Server LocalDB](#). LocalDB is a lightweight version of the SQL Server Express Database Engine and is intended for app development, not production use. LocalDB starts on demand and runs in user mode, so there's no complex configuration. By default, LocalDB creates `.mdf` DB files in the `c:/Users/<user>` directory.

## Add code to initialize the DB with test data

EF Core creates an empty DB. In this section, an `Initialize` method is written to populate it with test data.

In the `Data` folder, create a new class file named `DbInitializer.cs` and add the following code:

```
using ContosoUniversity.Models;
using System;
using System.Linq;

namespace ContosoUniversity.Data
{
    public static class DbInitializer
    {
        public static void Initialize(SchoolContext context)
        {
            // context.Database.EnsureCreated();

            // Look for any students.
            if (context.Student.Any())
            {
                // Add some sample data.
            }
        }
    }
}
```

```

        return; // DB has been seeded
    }

    var students = new Student[]
    {
        new Student{FirstMidName="Carson", LastName="Alexander", EnrollmentDate=DateTime.Parse("2005-09-01")},
        new Student{FirstMidName="Meredith", LastName="Alonso", EnrollmentDate=DateTime.Parse("2002-09-01")},
        new Student{FirstMidName="Arturo", LastName="Anand", EnrollmentDate=DateTime.Parse("2003-09-01")},
        new Student{FirstMidName="Gytis", LastName="Barzdukas", EnrollmentDate=DateTime.Parse("2002-09-01")},
        new Student{FirstMidName="Yan", LastName="Li", EnrollmentDate=DateTime.Parse("2002-09-01")},
        new Student{FirstMidName="Peggy", LastName="Justice", EnrollmentDate=DateTime.Parse("2001-09-01")},
        new Student{FirstMidName="Laura", LastName="Norman", EnrollmentDate=DateTime.Parse("2003-09-01")},
        new Student{FirstMidName="Nino", LastName="Olivetto", EnrollmentDate=DateTime.Parse("2005-09-01")}
    };
    foreach (Student s in students)
    {
        context.Student.Add(s);
    }
    context.SaveChanges();

    var courses = new Course[]
    {
        new Course{CourseID=1050, Title="Chemistry", Credits=3},
        new Course{CourseID=4022, Title="Microeconomics", Credits=3},
        new Course{CourseID=4041, Title="Macroeconomics", Credits=3},
        new Course{CourseID=1045, Title="Calculus", Credits=4},
        new Course{CourseID=3141, Title="Trigonometry", Credits=4},
        new Course{CourseID=2021, Title="Composition", Credits=3},
        new Course{CourseID=2042, Title="Literature", Credits=4}
    };
    foreach (Course c in courses)
    {
        context.Course.Add(c);
    }
    context.SaveChanges();

    var enrollments = new Enrollment[]
    {
        new Enrollment{StudentID=1, CourseID=1050, Grade=Grade.A},
        new Enrollment{StudentID=1, CourseID=4022, Grade=Grade.C},
        new Enrollment{StudentID=1, CourseID=4041, Grade=Grade.B},
        new Enrollment{StudentID=2, CourseID=1045, Grade=Grade.B},
        new Enrollment{StudentID=2, CourseID=3141, Grade=Grade.F},
        new Enrollment{StudentID=2, CourseID=2021, Grade=Grade.F},
        new Enrollment{StudentID=3, CourseID=1050},
        new Enrollment{StudentID=4, CourseID=1050},
        new Enrollment{StudentID=4, CourseID=4022, Grade=Grade.F},
        new Enrollment{StudentID=5, CourseID=4041, Grade=Grade.C},
        new Enrollment{StudentID=6, CourseID=1045},
        new Enrollment{StudentID=7, CourseID=3141, Grade=Grade.A},
    };
    foreach (Enrollment e in enrollments)
    {
        context.Enrollment.Add(e);
    }
    context.SaveChanges();
}
}

```

The code checks if there are any students in the DB. If there are no students in the DB, the DB is initialized with test data. It loads test data into arrays rather than `List<T>` collections to optimize performance.

The `EnsureCreated` method automatically creates the DB for the DB context. If the DB exists, `EnsureCreated` returns without modifying the DB.

In `Program.cs`, modify the `Main` method to call `Initialize`:

```
public class Program
{
    public static void Main(string[] args)
    {
        var host = CreateWebHostBuilder(args).Build();

        using (var scope = host.Services.CreateScope())
        {
            var services = scope.ServiceProvider;

            try
            {
                var context = services.GetRequiredService<SchoolContext>();
                // using ContosoUniversity.Data;
                DbInitializer.Initialize(context);
            }
            catch (Exception ex)
            {
                var logger = services.GetRequiredService<ILogger<Program>>();
                logger.LogError(ex, "An error occurred creating the DB.");
            }
        }

        host.Run();
    }

    public static IWebHostBuilder CreateWebHostBuilder(string[] args) =>
        WebHost.CreateDefaultBuilder(args)
            .UseStartup<Startup>();
}
```

Delete any student records and restart the app. If the DB is not initialized, set a break point in `Initialize` to diagnose the problem.

## View the DB

Open **SQL Server Object Explorer** (SSOX) from the **View** menu in Visual Studio. In SSOX, click **(localdb)\MSSQLLocalDB > Databases > ContosoUniversity1**.

Expand the **Tables** node.

Right-click the **Student** table and click **View Data** to see the columns created and the rows inserted into the table.

## Asynchronous code

Asynchronous programming is the default mode for ASP.NET Core and EF Core.

A web server has a limited number of threads available, and in high load situations all of the available threads might be in use. When that happens, the server can't process new requests until the threads are freed up. With synchronous code, many threads may be tied up while they aren't actually doing any work because they're waiting for I/O to complete. With asynchronous code, when a process is waiting for I/O to complete, its thread is freed up for the server to use for processing other requests. As a result, asynchronous code enables server resources to be used more efficiently, and the server is enabled to handle more traffic without delays.

Asynchronous code does introduce a small amount of overhead at run time. For low traffic situations, the performance hit is negligible, while for high traffic situations, the potential performance improvement is substantial.

In the following code, the `async` keyword, `Task<T>` return value, `await` keyword, and `ToListAsync` method make the code execute asynchronously.

```
public async Task OnGetAsync()
{
    Student = await _context.Student.ToListAsync();
}
```

- The `async` keyword tells the compiler to:
- Generate callbacks for parts of the method body.
- Automatically create the `Task` object that's returned. For more information, see [Task Return Type](#).
- The implicit return type `Task` represents ongoing work.
- The `await` keyword causes the compiler to split the method into two parts. The first part ends with the operation that's started asynchronously. The second part is put into a callback method that's called when the operation completes.
- `ToToListAsync` is the asynchronous version of the `ToList` extension method.

Some things to be aware of when writing asynchronous code that uses EF Core:

- Only statements that cause queries or commands to be sent to the DB are executed asynchronously. That includes, `ToToListAsync`, `SingleOrDefaultAsync`, `FirstOrDefaultAsync`, and `SaveChangesAsync`. It doesn't include statements that just change an `IQueryable`, such as  
`var students = context.Students.Where(s => s.LastName == "Davolio")`.
- An EF Core context isn't thread safe: don't try to do multiple operations in parallel.
- To take advantage of the performance benefits of async code, verify that library packages (such as for paging) use async if they call EF Core methods that send queries to the DB.

For more information about asynchronous programming in .NET, see [Async Overview](#) and [Asynchronous programming with async and await](#).

In the next tutorial, basic CRUD (create, read, update, delete) operations are examined.

[NEXT](#)

# Razor Pages with EF Core in ASP.NET Core - CRUD - 2 of 8

7/14/2018 • 11 minutes to read • [Edit Online](#)

The ASP.NET Core 2.0 version of this tutorial can be found in [this PDF file](#).

The ASP.NET Core 2.1 version of this tutorial has many improvements over the 2.0 version.

By [Tom Dykstra](#), [Jon P Smith](#), and [Rick Anderson](#)

The Contoso University web app demonstrates how to create Razor Pages web apps using EF Core and Visual Studio. For information about the tutorial series, see [the first tutorial](#).

In this tutorial, the scaffolded CRUD (create, read, update, delete) code is reviewed and customized.

To minimize complexity and keep these tutorials focused on EF Core, EF Core code is used in the page models. Some developers use a service layer or repository pattern in to create an abstraction layer between the UI (Razor Pages) and the data access layer.

In this tutorial, the Create, Edit, Delete, and Details Razor Pages in the *Student* folder are examined.

The scaffolded code uses the following pattern for Create, Edit, and Delete pages:

- Get and display the requested data with the HTTP GET method `OnGetAsync`.
- Save changes to the data with the HTTP POST method `OnPostAsync`.

The Index and Details pages get and display the requested data with the HTTP GET method `OnGetAsync`

## SingleOrDefaultAsync vs FirstOrDefaultAsync

The generated code uses `FirstOrDefaultAsync`, which is generally preferred over `SingleOrDefaultAsync`.

`FirstOrDefaultAsync` is more efficient than `SingleOrDefaultAsync` at fetching one entity:

- Unless the code needs to verify that there's not more than one entity returned from the query.
- `SingleOrDefaultAsync` fetches more data and does unnecessary work.
- `SingleOrDefaultAsync` throws an exception if there's more than one entity that fits the filter part.
- `FirstOrDefaultAsync` doesn't throw if there's more than one entity that fits the filter part.

### FindAsync

In much of the scaffolded code, `FindAsync` can be used in place of `FirstOrDefaultAsync`.

`FindAsync`:

- Finds an entity with the primary key (PK). If an entity with the PK is being tracked by the context, it's returned without a request to the DB.
- Is simple and concise.
- Is optimized to look up a single entity.
- Can have perf benefits in some situations, but they rarely happens for typical web apps.
- Implicitly uses `FirstAsync` instead of `SingleAsync`.

But if you want to `Include` other entities, then `FindAsync` is no longer appropriate. This means that you may need to abandon `FindAsync` and move to a query as your app progresses.

## Customize the Details page

Browse to `Pages/Students` page. The **Edit**, **Details**, and **Delete** links are generated by the [Anchor Tag Helper](#) in the `Pages/Students/Index.cshtml` file.

```
<td>
    <a asp-page=".Edit" asp-route-id="@item.ID">Edit</a> |
    <a asp-page=".Details" asp-route-id="@item.ID">Details</a> |
    <a asp-page=".Delete" asp-route-id="@item.ID">Delete</a>
</td>
```

Run the app and select a **Details** link. The URL is of the form `http://localhost:5000/Students/Details?id=2`. The Student ID is passed using a query string (`?id=2`).

Update the Edit, Details, and Delete Razor Pages to use the `"{id:int}"` route template. Change the page directive for each of these pages from `@page` to `@page "{id:int}"`.

A request to the page with the `"{id:int}"` route template that does **not** include a integer route value returns an HTTP 404 (not found) error. For example, `http://localhost:5000/Students/Details` returns a 404 error. To make the ID optional, append `?` to the route constraint:

```
@page "{id:int?}"
```

Run the app, click on a Details link, and verify the URL is passing the ID as route data (`http://localhost:5000/Students/Details/2`).

Don't globally change `@page` to `@page "{id:int}"`, doing so breaks the links to the Home and Create pages.

### Add related data

The scaffolded code for the Students Index page doesn't include the `Enrollments` property. In this section, the contents of the `Enrollments` collection is displayed in the Details page.

The `OnGetAsync` method of `Pages/Students/Details.cshtml.cs` uses the `FirstOrDefaultAsync` method to retrieve a single `Student` entity. Add the following highlighted code:

```
public async Task<IActionResult> OnGetAsync(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    Student = await _context.Student
        .Include(s => s.Enrollments)
        .ThenInclude(e => e.Course)
        .AsNoTracking()
        .FirstOrDefaultAsync(m => m.ID == id);

    if (Student == null)
    {
        return NotFound();
    }
    return Page();
}
```

The `Include` and `ThenInclude` methods cause the context to load the `Student.Enrollments` navigation property, and within each enrollment the `Enrollment.Course` navigation property. These methods are examined in detail in the reading-related data tutorial.

The [AsNoTracking](#) method improves performance in scenarios when the entities returned are not updated in the current context. `AsNoTracking` is discussed later in this tutorial.

### Display related enrollments on the Details page

Open `Pages/Students/Details.cshtml`. Add the following highlighted code to display a list of enrollments:

```

@page "{id:int}"
@model ContosoUniversity.Pages.Students.DetailsModel

@{
    ViewData["Title"] = "Details";
}

## Details

#### Student

---

    <dl class="dl-horizontal">
        <dt>
            @Html.DisplayNameFor(model => model.Student.LastName)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Student.LastName)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Student.FirstMidName)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Student.FirstMidName)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Student.EnrollmentDate)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Student.EnrollmentDate)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Student.Enrollments)
        </dt>
        <dd>
            <table class="table">
                <tr>
                    <th>Course Title</th>
                    <th>Grade</th>
                </tr>
                @foreach (var item in Model.Student.Enrollments)
                {
                    <tr>
                        <td>
                            @Html.DisplayFor(modelItem => item.Course.Title)
                        </td>
                        <td>
                            @Html.DisplayFor(modelItem => item.Grade)
                        </td>
                    </tr>
                }
            </table>
        </dd>
    </dl>

<div>
    <a asp-page=".Edit" asp-route-id="@Model.Student.ID">Edit</a> |
    <a asp-page=".Index">Back to List</a>
</div>

```

If code indentation is wrong after the code is pasted, press CTRL-K-D to correct it.

The preceding code loops through the entities in the `Enrollments` navigation property. For each enrollment, it displays the course title and the grade. The course title is retrieved from the Course entity that's stored in the `Course` navigation property of the Enrollments entity.

Run the app, select the **Students** tab, and click the **Details** link for a student. The list of courses and grades for the selected student is displayed.

## Update the Create page

Update the `OnPostAsync` method in *Pages/Students/Create.cshtml.cs* with the following code:

```
public async Task<IActionResult> OnPostAsync()
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    var emptyStudent = new Student();

    if (await TryUpdateModelAsync<Student>(
        emptyStudent,
        "student", // Prefix for form value.
        s => s.FirstMidName, s => s.LastName, s => s.EnrollmentDate))
    {
        _context.Student.Add(emptyStudent);
        await _context.SaveChangesAsync();
        return RedirectToPage("./Index");
    }

    return null;
}
```

### TryUpdateModelAsync

Examine the `TryUpdateModelAsync` code:

```
var emptyStudent = new Student();

if (await TryUpdateModelAsync<Student>(
    emptyStudent,
    "student", // Prefix for form value.
    s => s.FirstMidName, s => s.LastName, s => s.EnrollmentDate))
{
```

In the preceding code, `TryUpdateModelAsync<Student>` tries to update the `emptyStudent` object using the posted form values from the `PageContext` property in the `PageModel`. `TryUpdateModelAsync` only updates the properties listed (`s => s.FirstMidName, s => s.LastName, s => s.EnrollmentDate`).

In the preceding sample:

- The second argument (`"student", // Prefix`) is the prefix used to look up values. It's not case sensitive.
- The posted form values are converted to the types in the `Student` model using [model binding](#).

### Overposting

Using `TryUpdateModel` to update fields with posted values is a security best practice because it prevents overposting. For example, suppose the `Student` entity includes a `Secret` property that this web page shouldn't update or add:

```

public class Student
{
    public int ID { get; set; }
    public string LastName { get; set; }
    public string FirstMidName { get; set; }
    public DateTime EnrollmentDate { get; set; }
    public string Secret { get; set; }
}

```

Even if the app doesn't have a `Secret` field on the create/update Razor Page, a hacker could set the `Secret` value by overposting. A hacker could use a tool such as Fiddler, or write some JavaScript, to post a `Secret` form value. The original code doesn't limit the fields that the model binder uses when it creates a `Student` instance.

Whatever value the hacker specified for the `Secret` form field is updated in the DB. The following image shows the Fiddler tool adding the `Secret` field (with the value "OverPost") to the posted form values.

The screenshot shows the Fiddler interface with a red box highlighting the 'Execute' button. The 'Request Headers' section contains standard browser headers. The 'Request Body' section shows a URL-encoded form with the 'Secret' field explicitly added by the hacker.

The value "OverPost" is successfully added to the `Secret` property of the inserted row. The app designer never intended the `Secret` property to be set with the Create page.

### **View model**

A view model typically contains a subset of the properties included in the model used by the application. The application model is often called the domain model. The domain model typically contains all the properties required by the corresponding entity in the DB. The view model contains only the properties needed for the UI layer (for example, the Create page). In addition to the view model, some apps use a binding model or input model to pass data between the Razor Pages page model class and the browser. Consider the following `Student` view model:

```

using System;

namespace ContosoUniversity.Models
{
    public class StudentVM
    {
        public int ID { get; set; }
        public string LastName { get; set; }
        public string FirstMidName { get; set; }
        public DateTime EnrollmentDate { get; set; }
    }
}

```

View models provide an alternative way to prevent overposting. The view model contains only the properties to view (display) or update.

The following code uses the `StudentVM` view model to create a new student:

```

[BindProperty]
public StudentVM StudentVM { get; set; }

public async Task<IActionResult> OnPostAsync()
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    var entry = _context.Add(new Student());
    entry.CurrentValues.SetValues(StudentVM);
    await _context.SaveChangesAsync();
    return RedirectToPage("./Index");
}

```

The `SetValues` method sets the values of this object by reading values from another `PropertyValues` object.

`SetValues` uses property name matching. The view model type doesn't need to be related to the model type, it just needs to have properties that match.

Using `StudentVM` requires `CreateVM.cshtml` be updated to use `StudentVM` rather than `Student`.

In Razor Pages, the `PageModel` derived class is the view model.

## Update the Edit page

Update the page model for the Edit page. The major changes are highlighted:

```

public class EditModel : PageModel
{
    private readonly SchoolContext _context;

    public EditModel(SchoolContext context)
    {
        _context = context;
    }

    [BindProperty]
    public Student Student { get; set; }

    public async Task<IActionResult> OnGetAsync(int? id)
    {
        if (id == null)
        {
            return NotFound();
        }

        Student = await _context.Student.FindAsync(id);

        if (Student == null)
        {
            return NotFound();
        }
        return Page();
    }

    public async Task<IActionResult> OnPostAsync(int? id)
    {
        if (!ModelState.IsValid)
        {
            return Page();
        }

        var studentToUpdate = await _context.Student.FindAsync(id);

        if (await TryUpdateModelAsync<Student>(
            studentToUpdate,
            "student",
            s => s.FirstMidName, s => s.LastName, s => s.EnrollmentDate))
        {
            await _context.SaveChangesAsync();
            return RedirectToPage("./Index");
        }

        return Page();
    }
}

```

The code changes are similar to the Create page with a few exceptions:

- `OnPostAsync` has an optional `id` parameter.
- The current student is fetched from the DB, rather than creating an empty student.
- `FirstOrDefaultAsync` has been replaced with `FindAsync`. `FindAsync` is a good choice when selecting an entity from the primary key. See [FindAsync](#) for more information.

## Test the Edit and Create pages

Create and edit a few student entities.

## Entity States

The DB context keeps track of whether entities in memory are in sync with their corresponding rows in the DB.

The DB context sync information determines what happens when `SaveChangesAsync` is called. For example, when a new entity is passed to the `AddAsync` method, that entity's state is set to `Added`. When `SaveChangesAsync` is called, the DB context issues a SQL INSERT command.

An entity may be in one of the [following states](#):

- `Added`: The entity doesn't yet exist in the DB. The `SaveChanges` method issues an INSERT statement.
- `Unchanged`: No changes need to be saved with this entity. An entity has this status when it's read from the DB.
- `Modified`: Some or all of the entity's property values have been modified. The `SaveChanges` method issues an UPDATE statement.
- `Deleted`: The entity has been marked for deletion. The `SaveChanges` method issues a DELETE statement.
- `Detached`: The entity isn't being tracked by the DB context.

In a desktop app, state changes are typically set automatically. An entity is read, changes are made, and the entity state is automatically be changed to `Modified`. Calling `SaveChanges` generates a SQL UPDATE statement that updates only the changed properties.

In a web app, the `DbContext` that reads an entity and displays the data is disposed after a page is rendered. When a page's `OnPostAsync` method is called, a new web request is made and with a new instance of the `DbContext`. Re-reading the entity in that new context simulates desktop processing.

## Update the Delete page

In this section, code is added to implement a custom error message when the call to `SaveChanges` fails. Add a string to contain possible error messages:

```
public class DeleteModel : PageModel
{
    private readonly SchoolContext _context;

    public DeleteModel(SchoolContext context)
    {
        _context = context;
    }

    [BindProperty]
    public Student Student { get; set; }
    public string ErrorMessage { get; set; }
```

Replace the `OnGetAsync` method with the following code:

```

public async Task<IActionResult> OnGetAsync(int? id, bool? saveChangesError = false)
{
    if (id == null)
    {
        return NotFound();
    }

    Student = await _context.Student
        .AsNoTracking()
        .FirstOrDefaultAsync(m => m.ID == id);

    if (Student == null)
    {
        return NotFound();
    }

    if (saveChangesError.GetValueOrDefault())
    {
        ErrorMessage = "Delete failed. Try again";
    }

    return Page();
}

```

The preceding code contains the optional parameter `saveChangesError`. `saveChangesError` indicates whether the method was called after a failure to delete the student object. The delete operation might fail because of transient network problems. Transient network errors are more likely in the cloud. `saveChangesError` is false when the Delete page `OnGetAsync` is called from the UI. When `OnGetAsync` is called by `OnPostAsync` (because the delete operation failed), the `saveChangesError` parameter is true.

## The Delete pages `OnPostAsync` method

Replace the `OnPostAsync` with the following code:

```

public async Task<IActionResult> OnPostAsync(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var student = await _context.Student
        .AsNoTracking()
        .FirstOrDefaultAsync(m => m.ID == id);

    if (student == null)
    {
        return NotFound();
    }

    try
    {
        _context.Student.Remove(student);
        await _context.SaveChangesAsync();
        return RedirectToPage("./Index");
    }
    catch (DbUpdateException /* ex */)
    {
        //Log the error (uncomment ex variable name and write a log.)
        return RedirectToAction("./Delete",
            new { id, saveChangesError = true });
    }
}

```

The preceding code retrieves the selected entity, then calls the `Remove` method to set the entity's status to `Deleted`. When `SaveChanges` is called, a SQL DELETE command is generated. If `Remove` fails:

- The DB exception is caught.
- The Delete pages `OnGetAsync` method is called with `saveChangesError=true`.

## Update the Delete Razor Page

Add the following highlighted error message to the Delete Razor Page.

```
@page "{id:int}"
@model ContosoUniversity.Pages.Students.DeleteModel

@{
    ViewData["Title"] = "Delete";
}

<h2>Delete</h2>

<p class="text-danger">@Model.ErrorMessage</p>

<h3>Are you sure you want to delete this?</h3>
<div>
```

Test Delete.

## Common errors

Student/Index or other links don't work:

Verify the Razor Page contains the correct `@page` directive. For example, The Student/Index Razor Page should **not** contain a route template:

```
@page "{id:int}"
```

Each Razor Page must include the `@page` directive.

# Razor Pages with EF Core in ASP.NET Core - Sort, Filter, Paging - 3 of 8

6/28/2018 • 15 minutes to read • [Edit Online](#)

The ASP.NET Core 2.0 version of this tutorial can be found in [this PDF file](#).

The ASP.NET Core 2.1 version of this tutorial has many improvements over the 2.0 version.

By [Tom Dykstra](#), [Rick Anderson](#), and [Jon P Smith](#)

The Contoso University web app demonstrates how to create Razor Pages web apps using EF Core and Visual Studio. For information about the tutorial series, see [the first tutorial](#).

In this tutorial, sorting, filtering, grouping, and paging, functionality is added.

The following illustration shows a completed page. The column headings are clickable links to sort the column. Clicking a column heading repeatedly switches between ascending and descending sort order.

The screenshot shows a browser window for the 'Index - Contoso University' page. The URL is 'localhost:5813/Student'. The page title is 'Contoso University'. The main content area is titled 'Index' and contains a table of student data. At the top of the table, there are three column headers: 'Last Name', 'First Name', and 'Enrollment Date'. Below the table, there are two buttons: 'Previous' and 'Next'. The table data is as follows:

Last Name	First Name	Enrollment Date	Action
Alexander	Carson	9/1/2005 12:00:00 AM	Edit   Details   Delete
Alonso	Meredith	9/1/2002 12:00:00 AM	Edit   Details   Delete
Anand	Arturo	9/1/2003 12:00:00 AM	Edit   Details   Delete

If you run into problems you can't solve, download the [completed app](#).

## Add sorting to the Index page

Add strings to the `Students/Index.cshtml.cs` `PageModel` to contain the sorting parameters:

```

public class IndexModel : PageModel
{
    private readonly SchoolContext _context;

    public IndexModel(SchoolContext context)
    {
        _context = context;
    }

    public string NameSort { get; set; }
    public string DateSort { get; set; }
    public string CurrentFilter { get; set; }
    public string CurrentSort { get; set; }

```

Update the *Students/Index.cshtml.cs* `OnGetAsync` with the following code:

```

public async Task OnGetAsync(string sortOrder)
{
    NameSort = String.IsNullOrEmpty(sortOrder) ? "name_desc" : "";
    DateSort = sortOrder == "Date" ? "date_desc" : "Date";

    IQueryable<Student> studentIQ = from s in _context.Student
                                      select s;

    switch (sortOrder)
    {
        case "name_desc":
            studentIQ = studentIQ.OrderByDescending(s => s.LastName);
            break;
        case "Date":
            studentIQ = studentIQ.OrderBy(s => s.EnrollmentDate);
            break;
        case "date_desc":
            studentIQ = studentIQ.OrderByDescending(s => s.EnrollmentDate);
            break;
        default:
            studentIQ = studentIQ.OrderBy(s => s.LastName);
            break;
    }

    Student = await studentIQ.AsNoTracking().ToListAsync();
}

```

The preceding code receives a `sortOrder` parameter from the query string in the URL. The URL (including the query string) is generated by the [Anchor Tag Helper](#)

The `sortOrder` parameter is either "Name" or "Date." The `sortOrder` parameter is optionally followed by "\_desc" to specify descending order. The default sort order is ascending.

When the Index page is requested from the **Students** link, there's no query string. The students are displayed in ascending order by last name. Ascending order by last name is the default (fall-through case) in the `switch` statement. When the user clicks a column heading link, the appropriate `sortOrder` value is provided in the query string value.

`NameSort` and `DateSort` are used by the Razor Page to configure the column heading hyperlinks with the appropriate query string values:

```

public async Task OnGetAsync(string sortOrder)
{
    NameSort = String.IsNullOrEmpty(sortOrder) ? "name_desc" : "";
    DateSort = sortOrder == "Date" ? "date_desc" : "Date";

    IQueryable<Student> studentIQ = from s in _context.Student
                                      select s;

    switch (sortOrder)
    {
        case "name_desc":
            studentIQ = studentIQ.OrderByDescending(s => s.LastName);
            break;
        case "Date":
            studentIQ = studentIQ.OrderBy(s => s.EnrollmentDate);
            break;
        case "date_desc":
            studentIQ = studentIQ.OrderByDescending(s => s.EnrollmentDate);
            break;
        default:
            studentIQ = studentIQ.OrderBy(s => s.LastName);
            break;
    }

    Student = await studentIQ.AsNoTracking().ToListAsync();
}

```

The following code contains the C# conditional `?:` operator:

```

NameSort = String.IsNullOrEmpty(sortOrder) ? "name_desc" : "";
DateSort = sortOrder == "Date" ? "date_desc" : "Date";

```

The first line specifies that when `sortOrder` is null or empty, `NameSort` is set to "name\_desc." If `sortOrder` is **not** null or empty, `NameSort` is set to an empty string.

The `?:` operator is also known as the ternary operator.

These two statements enable the page to set the column heading hyperlinks as follows:

CURRENT SORT ORDER	LAST NAME HYPERLINK	DATE HYPERLINK
Last Name ascending	descending	ascending
Last Name descending	ascending	ascending
Date ascending	ascending	descending
Date descending	ascending	ascending

The method uses LINQ to Entities to specify the column to sort by. The code initializes an `IQueryable<Student>` before the switch statement, and modifies it in the switch statement:

```

public async Task OnGetAsync(string sortOrder)
{
    NameSort = String.IsNullOrEmpty(sortOrder) ? "name_desc" : "";
    DateSort = sortOrder == "Date" ? "date_desc" : "Date";

    IQueryable<Student> studentIQ = from s in _context.Student
                                      select s;

    switch (sortOrder)
    {
        case "name_desc":
            studentIQ = studentIQ.OrderByDescending(s => s.LastName);
            break;
        case "Date":
            studentIQ = studentIQ.OrderBy(s => s.EnrollmentDate);
            break;
        case "date_desc":
            studentIQ = studentIQ.OrderByDescending(s => s.EnrollmentDate);
            break;
        default:
            studentIQ = studentIQ.OrderBy(s => s.LastName);
            break;
    }

    Student = await studentIQ.AsNoTracking().ToListAsync();
}

```

When an `IQueryable` is created or modified, no query is sent to the database. The query isn't executed until the `IQueryable` object is converted into a collection. `IQueryable` are converted to a collection by calling a method such as `ToListAsync`. Therefore, the `IQueryable` code results in a single query that's not executed until the following statement:

```
Student = await studentIQ.AsNoTracking().ToListAsync();
```

`OnGetAsync` could get verbose with a large number of sortable columns.

### Add column heading hyperlinks to the Student Index page

Replace the code in `Students/Index.cshtml`, with the following highlighted code:

```

@page
@model ContosoUniversity.Pages.Students.IndexModel

 @{
     ViewData["Title"] = "Index";
 }

<h2>Index</h2>
<p>
    <a asp-page="Create">Create New</a>
</p>

<table class="table">
    <thead>
        <tr>
            <th>
                <a asp-page="./Index" asp-route-sortOrder="@Model.NameSort">
                    @Html.DisplayNameFor(model => model.Student[0].LastName)
                </a>
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Student[0].FirstMidName)
            </th>
            <th>
                <a asp-page="./Index" asp-route-sortOrder="@Model.DateSort">
                    @Html.DisplayNameFor(model => model.Student[0].EnrollmentDate)
                </a>
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
        @foreach (var item in Model.Student)
        {
            <tr>
                <td>
                    @Html.DisplayFor(modelItem => item.LastName)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.FirstMidName)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.EnrollmentDate)
                </td>
                <td>
                    <a asp-page="./Edit" asp-route-id="@item.ID">Edit</a> |
                    <a asp-page="./Details" asp-route-id="@item.ID">Details</a> |
                    <a asp-page=".Delete" asp-route-id="@item.ID">Delete</a>
                </td>
            </tr>
        }
    </tbody>
</table>

```

The preceding code:

- Adds hyperlinks to the `LastName` and `EnrollmentDate` column headings.
- Uses the information in `NameSort` and `DateSort` to set up hyperlinks with the current sort order values.

To verify that sorting works:

- Run the app and select the **Students** tab.
- Click **Last Name**.
- Click **Enrollment Date**.

To get a better understanding of the code:

- In *Student/Index.cshtml.cs*, set a breakpoint on `switch (sortOrder)`.
- Add a watch for `NameSort` and `DateSort`.
- In *Student/Index.cshtml*, set a breakpoint on `@Html.DisplayNameFor(model => model.Student[0].LastName)`.

Step through the debugger.

## Add a Search Box to the Students Index page

To add filtering to the Students Index page:

- A text box and a submit button is added to the Razor Page. The text box supplies a search string on the first or last name.
- The page model is updated to use the text box value.

### Add filtering functionality to the Index method

Update the *Students/Index.cshtml.cs* `OnGetAsync` with the following code:

```
public async Task OnGetAsync(string sortOrder, string searchString)
{
    NameSort = String.IsNullOrEmpty(sortOrder) ? "name_desc" : "";
    DateSort = sortOrder == "Date" ? "date_desc" : "Date";
    CurrentFilter = searchString;

    IQueryable<Student> studentIQ = from s in _context.Student
                                         select s;
    if (!String.IsNullOrEmpty(searchString))
    {
        studentIQ = studentIQ.Where(s => s.LastName.Contains(searchString)
                               || s.FirstMidName.Contains(searchString));
    }

    switch (sortOrder)
    {
        case "name_desc":
            studentIQ = studentIQ.OrderByDescending(s => s.LastName);
            break;
        case "Date":
            studentIQ = studentIQ.OrderBy(s => s.EnrollmentDate);
            break;
        case "date_desc":
            studentIQ = studentIQ.OrderByDescending(s => s.EnrollmentDate);
            break;
        default:
            studentIQ = studentIQ.OrderBy(s => s.LastName);
            break;
    }

    Student = await studentIQ.AsNoTracking().ToListAsync();
}
```

The preceding code:

- Adds the `searchString` parameter to the `OnGetAsync` method. The search string value is received from a text box that's added in the next section.
- Added to the LINQ statement a `Where` clause. The `Where` clause selects only students whose first name or last name contains the search string. The LINQ statement is executed only if there's a value to search for.

Note: The preceding code calls the `Where` method on an `IQueryable` object, and the filter is processed on the server. In some scenarios, the app might be calling the `Where` method as an extension method on an in-memory

collection. For example, suppose `_context.Students` changes from EF Core `dbSet` to a repository method that returns an `IEnumerable` collection. The result would normally be the same but in some cases may be different.

For example, the .NET Framework implementation of `Contains` performs a case-sensitive comparison by default. In SQL Server, `Contains` case-sensitivity is determined by the collation setting of the SQL Server instance. SQL Server defaults to case-insensitive. `ToUpper` could be called to make the test explicitly case-insensitive:

```
Where(s => s.LastName.ToUpper().Contains(searchString.ToUpper()))
```

The preceding code would ensure that results are case-insensitive if the code changes to use `IEnumerable`. When `Contains` is called on an `IEnumerable` collection, the .NET Core implementation is used. When `contains` is called on an `IQueryable` object, the database implementation is used. Returning an `IEnumerable` from a repository can have a significant performance penalty:

1. All the rows are returned from the DB server.
2. The filter is applied to all the returned rows in the application.

There's a performance penalty for calling `ToUpper`. The `ToUpper` code adds a function in the WHERE clause of the TSQL SELECT statement. The added function prevents the optimizer from using an index. Given that SQL is installed as case-insensitive, it's best to avoid the `ToUpper` call when it's not needed.

## Add a Search Box to the Student Index page

In `Pages/Students/Index.cshtml`, add the following highlighted code to create a **Search** button and assorted chrome.

```
@page
@model ContosoUniversity.Pages.Students.IndexModel

 @{
    ViewData["Title"] = "Index";
}

<h2>Index</h2>

<p>
    <a asp-page="Create">Create New</a>
</p>

<form asp-page=".Index" method="get">
    <div class="form-actions no-color">
        <p>
            Find by name:
            <input type="text" name="SearchString" value="@Model.CurrentFilter" />
            <input type="submit" value="Search" class="btn btn-default" /> |
            <a asp-page=".Index">Back to full List</a>
        </p>
    </div>
</form>

<table class="table">
```

The preceding code uses the `<form>` tag helper to add the search text box and button. By default, the `<form>` tag helper submits form data with a POST. With POST, the parameters are passed in the HTTP message body and not in the URL. When HTTP GET is used, the form data is passed in the URL as query strings. Passing the data with query strings enables users to bookmark the URL. The [W3C guidelines](#) recommend that GET should be used when the action doesn't result in an update.

Test the app:

- Select the **Students** tab and enter a search string.

- Select **Search**.

Notice that the URL contains the search string.

```
http://localhost:5000/Students?SearchString=an
```

If the page is bookmarked, the bookmark contains the URL to the page and the `SearchString` query string. The `method="get"` in the `form` tag is what caused the query string to be generated.

Currently, when a column heading sort link is selected, the filter value from the **Search** box is lost. The lost filter value is fixed in the next section.

## Add paging functionality to the Students Index page

In this section, a `PaginatedList` class is created to support paging. The `PaginatedList` class uses `Skip` and `Take` statements to filter data on the server instead of retrieving all rows of the table. The following illustration shows the paging buttons.

The screenshot shows a web browser window titled "Index - Contoso University". The address bar displays "localhost:5813/Student". The main content area is titled "Index" and contains a table of student data. At the top of the table, there are three columns: "Last Name", "First Name", and "Enrollment Date". Below the table, there are three student records:

Last Name	First Name	Enrollment Date	Action
Alexander	Carson	9/1/2005 12:00:00 AM	Edit   Details   Delete
Alonso	Meredith	9/1/2002 12:00:00 AM	Edit   Details   Delete
Anand	Arturo	9/1/2003 12:00:00 AM	Edit   Details   Delete

At the bottom of the table, there are two buttons: "Previous" and "Next".

In the project folder, create `PaginatedList.cs` with the following code:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Threading.Tasks;
using Microsoft.EntityFrameworkCore;

namespace ContosoUniversity
{
    public class PaginatedList<T> : List<T>
    {
        public int PageIndex { get; private set; }
        public int TotalPages { get; private set; }

        public PaginatedList(List<T> items, int count, int pageIndex, int pageSize)
        {
            PageIndex = pageIndex;
            TotalPages = (int)Math.Ceiling(count / (double)pageSize);

            this.AddRange(items);
        }

        public bool HasPreviousPage
        {
            get
            {
                return (PageIndex > 1);
            }
        }

        public bool HasNextPage
        {
            get
            {
                return (PageIndex < TotalPages);
            }
        }

        public static async Task<PaginatedList<T>> CreateAsync(
            IQueryable<T> source, int pageIndex, int pageSize)
        {
            var count = await source.CountAsync();
            var items = await source.Skip(
                (pageIndex - 1) * pageSize)
                .Take(pageSize).ToListAsync();
            return new PaginatedList<T>(items, count, pageIndex, pageSize);
        }
    }
}

```

The `CreateAsync` method in the preceding code takes page size and page number and applies the appropriate `Skip` and `Take` statements to the `IQueryable`. When `ToListAsync` is called on the `IQueryable`, it returns a List containing only the requested page. The properties `HasPreviousPage` and `HasNextPage` are used to enable or disable **Previous** and **Next** paging buttons.

The `CreateAsync` method is used to create the `PaginatedList<T>`. A constructor can't create the `PaginatedList<T>` object, constructors can't run asynchronous code.

## Add paging functionality to the Index method

In `Students/Index.cshtml.cs`, update the type of `Student` from `IList<Student>` to `PaginatedList<Student>`:

```
public PaginatedList<Student> Student { get; set; }
```

Update the `Students/Index.cshtml.cs` `OnGetAsync` with the following code:

```
public async Task OnGetAsync(string sortOrder,
    string currentFilter, string searchString, int? pageIndex)
{
    CurrentSort = sortOrder;
    NameSort = String.IsNullOrEmpty(sortOrder) ? "name_desc" : "";
    DateSort = sortOrder == "Date" ? "date_desc" : "Date";
    if (searchString != null)
    {
        pageIndex = 1;
    }
    else
    {
        searchString = currentFilter;
    }

    CurrentFilter = searchString;

    IQueryable<Student> studentIQ = from s in _context.Student
                                         select s;
    if (!String.IsNullOrEmpty(searchString))
    {
        studentIQ = studentIQ.Where(s => s.LastName.Contains(searchString)
                               || s.FirstMidName.Contains(searchString));
    }
    switch (sortOrder)
    {
        case "name_desc":
            studentIQ = studentIQ.OrderByDescending(s => s.LastName);
            break;
        case "Date":
            studentIQ = studentIQ.OrderBy(s => s.EnrollmentDate);
            break;
        case "date_desc":
            studentIQ = studentIQ.OrderByDescending(s => s.EnrollmentDate);
            break;
        default:
            studentIQ = studentIQ.OrderBy(s => s.LastName);
            break;
    }

    int pageSize = 3;
    Student = await PaginatedList<Student>.CreateAsync(
        studentIQ.AsNoTracking(), pageIndex ?? 1, pageSize);
}
```

The preceding code adds the page index, the current `sortOrder`, and the `currentFilter` to the method signature.

```
public async Task OnGetAsync(string sortOrder,
    string currentFilter, string searchString, int? pageIndex)
```

All the parameters are null when:

- The page is called from the **Students** link.
- The user hasn't clicked a paging or sorting link.

When a paging link is clicked, the page index variable contains the page number to display.

`CurrentSort` provides the Razor Page with the current sort order. The current sort order must be included in the paging links to keep the sort order while paging.

`CurrentFilter` provides the Razor Page with the current filter string. The `CurrentFilter` value:

- Must be included in the paging links in order to maintain the filter settings during paging.
- Must be restored to the text box when the page is redisplayed.

If the search string is changed while paging, the page is reset to 1. The page has to be reset to 1 because the new filter can result in different data to display. When a search value is entered and **Submit** is selected:

- The search string is changed.
- The `searchString` parameter isn't null.

```
if (searchString != null)
{
    pageIndex = 1;
}
else
{
    searchString = currentFilter;
}
```

The `PaginatedList.CreateAsync` method converts the student query to a single page of students in a collection type that supports paging. That single page of students is passed to the Razor Page.

```
Student = await PaginatedList<Student>.CreateAsync(
    studentIQ.AsNoTracking(), pageIndex ?? 1, pageSize);
```

The two question marks in `PaginatedList.CreateAsync` represent the [null-coalescing operator] (<https://docs.microsoft.com/dotnet/csharp/language-reference/operators/null-conditional-operator>). The null-coalescing operator defines a default value for a nullable type. The expression `(pageIndex ?? 1)` means return the value of `pageIndex` if it has a value. If `pageIndex` doesn't have a value, return 1.

## Add paging links to the student Razor Page

Update the markup in `Students/Index.cshtml`. The changes are highlighted:

```
@page
@model ContosoUniversity.Pages.Students.IndexModel

 @{
     ViewData["Title"] = "Index";
 }

<h2>Index</h2>

<p>
    <a asp-page="Create">Create New</a>
</p>

<form asp-page=".Index" method="get">
    <div class="form-actions no-color">
        <p>
            Find by name: <input type="text" name="SearchString" value="@Model.CurrentFilter" />
            <input type="submit" value="Search" class="btn btn-default" /> |
            <a asp-page=".Index">Back to full List</a>
        </p>
    </div>
</form>

<table class="table">
    <thead>
        <tr>
            <th>
```

```

        <a asp-page=".Index" asp-route-sortOrder="@Model.NameSort"
           asp-route-currentFilter="@Model.CurrentFilter">
            @Html.DisplayNameFor(model => model.Student[0].LastName)
        </a>
    </th>
    <th>
        @Html.DisplayNameFor(model => model.Student[0].FirstMidName)
    </th>
    <th>
        <a asp-page=".Index" asp-route-sortOrder="@Model.DateSort"
           asp-route-currentFilter="@Model.CurrentFilter">
            @Html.DisplayNameFor(model => model.Student[0].EnrollmentDate)
        </a>
    </th>
    <th></th>
</tr>
</thead>
<tbody>
    @foreach (var item in Model.Student)
    {
        <tr>
            <td>
                @Html.DisplayFor(modelItem => item.LastName)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.FirstMidName)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.EnrollmentDate)
            </td>
            <td>
                <a asp-page=".Edit" asp-route-id="@item.ID">Edit</a> |
                <a asp-page=".Details" asp-route-id="@item.ID">Details</a> |
                <a asp-page=".Delete" asp-route-id="@item.ID">Delete</a>
            </td>
        </tr>
    }
</tbody>
</table>

@{
    var prevDisabled = !Model.Student.HasPreviousPage ? "disabled" : "";
    var nextDisabled = !Model.Student.HasNextPage ? "disabled" : "";
}

<a asp-page=".Index"
   asp-route-sortOrder="@Model.CurrentSort"
   asp-route-pageIndex="@((Model.StudentPageIndex - 1))"
   asp-route-currentFilter="@Model.CurrentFilter"
   class="btn btn-default @prevDisabled">
    Previous
</a>
<a asp-page=".Index"
   asp-route-sortOrder="@Model.CurrentSort"
   asp-route-pageIndex="@((Model.StudentPageIndex + 1))"
   asp-route-currentFilter="@Model.CurrentFilter"
   class="btn btn-default @nextDisabled">
    Next
</a>

```

The column header links use the query string to pass the current search string to the `OnGetAsync` method so that the user can sort within filter results:

```

<a asp-page=".~/Index" asp-route-sortOrder="@Model.NameSort"
    asp-route-currentFilter="@Model.CurrentFilter">
    @Html.DisplayNameFor(model => model.Student[0].LastName)
</a>

```

The paging buttons are displayed by tag helpers:

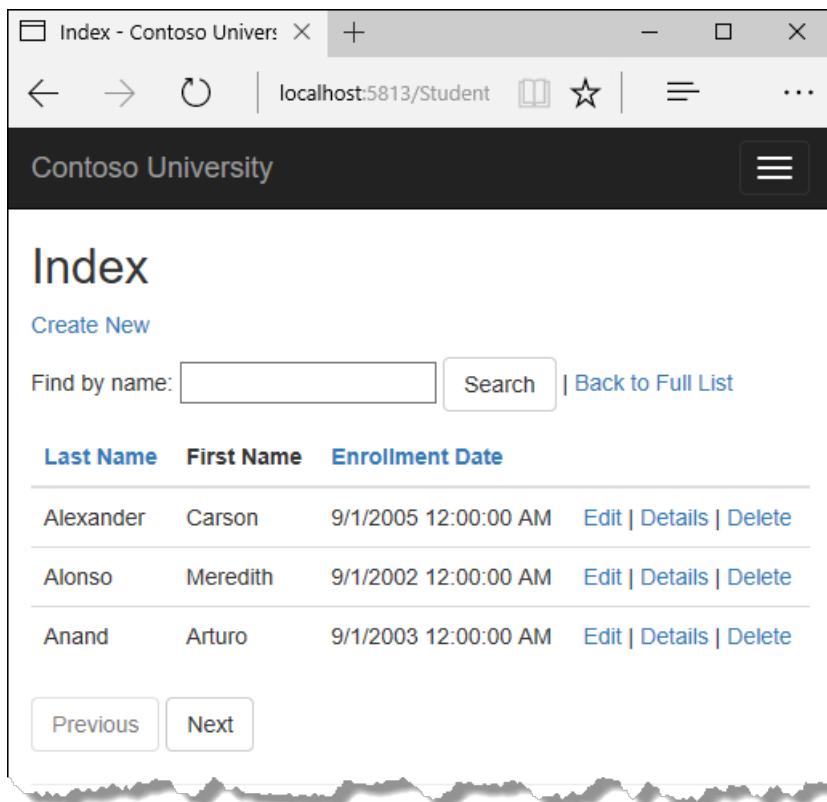

```

<a asp-page=".~/Index"
    asp-route-sortOrder="@Model.CurrentSort"
    asp-route-pageIndex="@Model.Student.PageIndex - 1"
    asp-route-currentFilter="@Model.CurrentFilter"
    class="btn btn-default @prevDisabled">
    Previous
</a>
<a asp-page=".~/Index"
    asp-route-sortOrder="@Model.CurrentSort"
    asp-route-pageIndex="@Model.Student.PageIndex + 1"
    asp-route-currentFilter="@Model.CurrentFilter"
    class="btn btn-default @nextDisabled">
    Next
</a>

```

Run the app and navigate to the students page.

- To make sure paging works, click the paging links in different sort orders.
- To verify that paging works correctly with sorting and filtering, enter a search string and try paging.

To get a better understanding of the code:

- In *Student/Index.cshtml.cs*, set a breakpoint on `switch (sortOrder)`.
- Add a watch for `NameSort`, `DateSort`, `CurrentSort`, and `Model.StudentPageIndex`.
- In *Student/Index.cshtml*, set a breakpoint on `@Html.DisplayNameFor(model => model.Student[0].LastName)`.

Step through the debugger.

## Update the About page to show student statistics

In this step, *Pages/About.cshtml* is updated to display how many students have enrolled for each enrollment date.

The update uses grouping and includes the following steps:

- Create a view model for the data used by the **About** Page.
- Update the About page to use the view model.

### Create the view model

Create a *SchoolViewModels* folder in the *Models* folder.

In the *SchoolViewModels* folder, add a *EnrollmentDateGroup.cs* with the following code:

```
using System;
using System.ComponentModel.DataAnnotations;

namespace ContosoUniversity.Models.SchoolViewModels
{
    public class EnrollmentDateGroup
    {
        [DataType(DataType.Date)]
        public DateTime? EnrollmentDate { get; set; }

        public int StudentCount { get; set; }
    }
}
```

### Update the About page model

Update the *Pages/About.cshtml.cs* file with the following code:

```

using ContosoUniversity.Models.SchoolViewModels;
using Microsoft.AspNetCore.Mvc.RazorPages;
using Microsoft.EntityFrameworkCore;
using System.Collections.Generic;
using System.Linq;
using System.Threading.Tasks;
using ContosoUniversity.Models;
using ContosoUniversity.Data;

namespace ContosoUniversity.Pages
{
    public class AboutModel : PageModel
    {
        private readonly SchoolContext _context;

        public AboutModel(SchoolContext context)
        {
            _context = context;
        }

        public IList<EnrollmentDateGroup> Student { get; set; }

        public async Task OnGetAsync()
        {
            IQueryable<EnrollmentDateGroup> data =
                from student in _context.Student
                group student by student.EnrollmentDate into dateGroup
                select new EnrollmentDateGroup()
                {
                    EnrollmentDate = dateGroup.Key,
                    StudentCount = dateGroup.Count()
                };
            Student = await data.AsNoTracking().ToListAsync();
        }
    }
}

```

The LINQ statement groups the student entities by enrollment date, calculates the number of entities in each group, and stores the results in a collection of `EnrollmentDateGroup` view model objects.

Note: The LINQ `group` command isn't currently supported by EF Core. In the preceding code, all the student records are returned from SQL Server. The `group` command is applied in the Razor Pages app, not on the SQL Server. EF Core 2.1 will support this LINQ `group` operator, and the grouping occurs on the SQL Server. See [Relational: Support translating GroupBy\(\) to SQL](#). EF Core 2.1 will be released with .NET Core 2.1. For more information, see the [.NET Core Roadmap](#).

## Modify the About Razor Page

Replace the code in the `Pages/Aabout.cshtml` file with the following code:

```

@page
@model ContosoUniversity.Pages.AboutModel

 @{
     ViewData["Title"] = "Student Body Statistics";
 }

<h2>Student Body Statistics</h2>

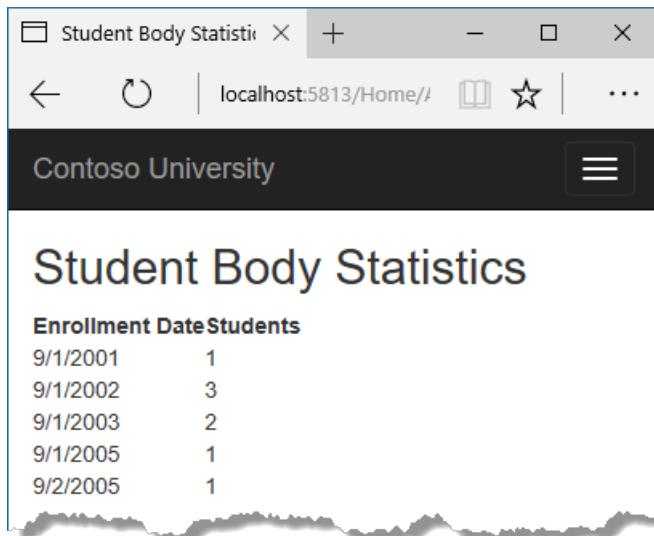

```

Run the app and navigate to the About page. The count of students for each enrollment date is displayed in a table.

If you run into problems you can't solve, download the [completed app for this stage](#).

In the next tutorial, the app uses migrations to update the data model.

# Razor Pages with EF Core in ASP.NET Core - Migrations - 4 of 8

7/10/2018 • 5 minutes to read • [Edit Online](#)

The ASP.NET Core 2.0 version of this tutorial can be found in [this PDF file](#).

The ASP.NET Core 2.1 version of this tutorial has many improvements over the 2.0 version.

By [Tom Dykstra](#), [Jon P Smith](#), and [Rick Anderson](#)

The Contoso University web app demonstrates how to create Razor Pages web apps using EF Core and Visual Studio. For information about the tutorial series, see [the first tutorial](#).

In this tutorial, the EF Core migrations feature for managing data model changes is used.

If you run into problems you can't solve, download the [completed app](#).

When a new app is developed, the data model changes frequently. Each time the model changes, the model gets out of sync with the database. This tutorial started by configuring the Entity Framework to create the database if it doesn't exist. Each time the data model changes:

- The DB is dropped.
- EF creates a new one that matches the model.
- The app seeds the DB with test data.

This approach to keeping the DB in sync with the data model works well until you deploy the app to production. When the app is running in production, it's usually storing data that needs to be maintained. The app can't start with a test DB each time a change is made (such as adding a new column). The EF Core Migrations feature solves this problem by enabling EF Core to update the DB schema instead of creating a new DB.

Rather than dropping and recreating the DB when the data model changes, migrations updates the schema and retains existing data.

## Drop the database

Use **SQL Server Object Explorer** (SSOX) or the `database drop` command:

- [Visual Studio](#)
- [.NET Core CLI](#)

In the **Package Manager Console** (PMC), run the following command:

```
Drop-Database
```

Run `Get-Help about_EntityFrameworkCore` from the PMC to get help information.

## Create an initial migration and update the DB

Build the project and create the first migration.

- [Visual Studio](#)
- [.NET Core CLI](#)

```
Add-Migration InitialCreate  
Update-Database
```

## Examine the Up and Down methods

The EF Core `migrations add` command generated code to create the DB. This migrations code is in the `Migrations<timestamp>_InitialCreate.cs` file. The `Up` method of the `InitialCreate` class creates the DB tables that correspond to the data model entity sets. The `Down` method deletes them, as shown in the following example:

```
public partial class InitialCreate : Migration
{
    protected override void Up(MigrationBuilder migrationBuilder)
    {
        migrationBuilder.CreateTable(
            name: "Course",
            columns: table => new
            {
                CourseID = table.Column<int>(nullable: false),
                Title = table.Column<string>(nullable: true),
                Credits = table.Column<int>(nullable: false)
            },
            constraints: table =>
            {
                table.PrimaryKey("PK_Course", x => x.CourseID);
            });
    }

    protected override void Down(MigrationBuilder migrationBuilder)
    {
        migrationBuilder.DropTable(
            name: "Enrollment");

        migrationBuilder.DropTable(
            name: "Course");

        migrationBuilder.DropTable(
            name: "Student");
    }
}
```

Migrations calls the `Up` method to implement the data model changes for a migration. When you enter a command to roll back the update, migrations calls the `Down` method.

The preceding code is for the initial migration. That code was created when the `migrations add InitialCreate` command was run. The migration name parameter ("InitialCreate" in the example) is used for the file name. The migration name can be any valid file name. It's best to choose a word or phrase that summarizes what is being done in the migration. For example, a migration that added a department table might be called "AddDepartmentTable."

If the initial migration is created and the DB exists:

- The DB creation code is generated.
- The DB creation code doesn't need to run because the DB already matches the data model. If the DB creation code is run, it doesn't make any changes because the DB already matches the data model.

When the app is deployed to a new environment, the DB creation code must be run to create the DB.

Previously the DB was dropped and doesn't exist, so migrations creates the new DB.

## The data model snapshot

Migrations create a *snapshot* of the current database schema in `Migrations/SchoolContextModelSnapshot.cs`.

When you add a migration, EF determines what changed by comparing the data model to the snapshot file.

To delete a migration, use the following command:

- [Visual Studio](#)
- [.NET Core CLI](#)

`Remove-Migration`

The remove migrations command deletes the migration and ensures the snapshot is correctly reset.

### Remove EnsureCreated and test the app

For early development, `EnsureCreated` was used. In this tutorial, migrations are used. `EnsureCreated` has the following limitations:

- Bypasses migrations and creates the DB and schema.
- Doesn't create a migrations table.
- Can *not* be used with migrations.
- Is designed for testing or rapid prototyping where the DB is dropped and re-created frequently.

Remove the following line from `DbInitializer`:

```
context.Database.EnsureCreated();
```

Run the app and verify the DB is seeded.

### Inspect the database

Use **SQL Server Object Explorer** to inspect the DB. Notice the addition of an `__EFMigrationsHistory` table. The `__EFMigrationsHistory` table keeps track of which migrations have been applied to the DB. View the data in the `__EFMigrationsHistory` table, it shows one row for the first migration. The last log in the preceding CLI output example shows the INSERT statement that creates this row.

Run the app and verify that everything works.

## Applying migrations in production

We recommend production apps should **not** call `Database.Migrate` at application startup. `Migrate` shouldn't be called from an app in server farm. For example, if the app has been cloud deployed with scale-out (multiple instances of the app are running).

Database migration should be done as part of deployment, and in a controlled way. Production database migration approaches include:

- Using migrations to create SQL scripts and using the SQL scripts in deployment.
- Running `dotnet ef database update` from a controlled environment.

EF Core uses the `__MigrationsHistory` table to see if any migrations need to run. If the DB is up-to-date, no migration is run.

## Troubleshooting

Download the [completed app](#).

The app generates the following exception:

```
SqlException: Cannot open database "ContosoUniversity" requested by the login.  
The login failed.  
Login failed for user 'user name'.
```

Solution: Run `dotnet ef database update`

# Razor Pages with EF Core in ASP.NET Core - Data Model - 5 of 8

6/28/2018 • 28 minutes to read • [Edit Online](#)

The ASP.NET Core 2.0 version of this tutorial can be found in [this PDF file](#).

The ASP.NET Core 2.1 version of this tutorial has many improvements over the 2.0 version.

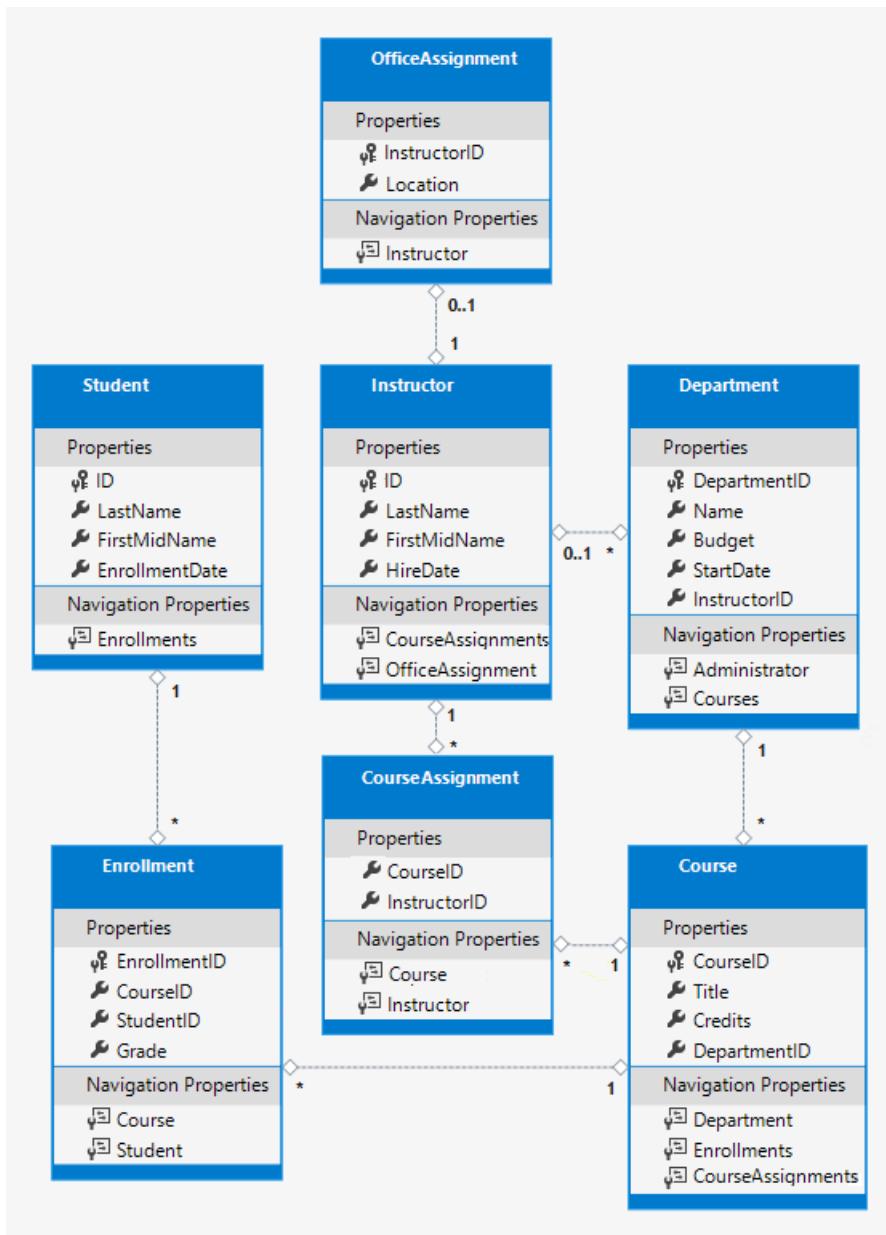

By [Tom Dykstra](#) and [Rick Anderson](#)

The Contoso University web app demonstrates how to create Razor Pages web apps using EF Core and Visual Studio. For information about the tutorial series, see [the first tutorial](#).

The previous tutorials worked with a basic data model that was composed of three entities. In this tutorial:

- More entities and relationships are added.
- The data model is customized by specifying formatting, validation, and database mapping rules.

The entity classes for the completed data model is shown in the following illustration:

If you run into problems you can't solve, download the [completed app](#).

## Customize the data model with attributes

In this section, the data model is customized using attributes.

### The `DataType` attribute

The student pages currently displays the time of the enrollment date. Typically, date fields show only the date and not the time.

Update `Models/Student.cs` with the following highlighted code:

```

using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;

namespace ContosoUniversity.Models
{
    public class Student
    {
        public int ID { get; set; }
        public string LastName { get; set; }
        public string FirstMidName { get; set; }
        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        public DateTime EnrollmentDate { get; set; }

        public ICollection<Enrollment> Enrollments { get; set; }
    }
}

```

The `DataType` attribute specifies a data type that's more specific than the database intrinsic type. In this case only the date should be displayed, not the date and time. The [DataType Enumeration](#) provides for many data types, such as Date, Time, PhoneNumber, Currency, EmailAddress, etc. The `DataType` attribute can also enable the app to automatically provide type-specific features. For example:

- The `mailto:` link is automatically created for `DataType.EmailAddress`.
- The date selector is provided for `DataType.Date` in most browsers.

The `DataType` attribute emits HTML 5 `data-` (pronounced data dash) attributes that HTML 5 browsers consume. The `DataType` attributes don't provide validation.

`DataType.Date` doesn't specify the format of the date that's displayed. By default, the date field is displayed according to the default formats based on the server's [CultureInfo](#).

The `DisplayFormat` attribute is used to explicitly specify the date format:

```
[DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
```

The `ApplyFormatInEditMode` setting specifies that the formatting should also be applied to the edit UI. Some fields shouldn't use `ApplyFormatInEditMode`. For example, the currency symbol should generally not be displayed in an edit text box.

The `DisplayFormat` attribute can be used by itself. It's generally a good idea to use the `DataType` attribute with the `DisplayFormat` attribute. The `DataType` attribute conveys the semantics of the data as opposed to how to render it on a screen. The `DataType` attribute provides the following benefits that are not available in `DisplayFormat`:

- The browser can enable HTML5 features. For example, show a calendar control, the locale-appropriate currency symbol, email links, client-side input validation, etc.
- By default, the browser renders data using the correct format based on the locale.

For more information, see the [<input> Tag Helper documentation](#).

Run the app. Navigate to the Students Index page. Times are no longer displayed. Every view that uses the `Student` model displays the date without time.

Last Name	First Name	Enrollment Date	
Alexander	Carson	2005-09-01	Edit   Details   Delete
Alonso	Meredith	2002-09-01	Edit   Details   Delete
Anand	Arturo	2003-09-01	Edit   Details   Delete

## The StringLength attribute

Data validation rules and validation error messages can be specified with attributes. The `StringLength` attribute specifies the minimum and maximum length of characters that are allowed in a data field. The `StringLength` attribute also provides client-side and server-side validation. The minimum value has no impact on the database schema.

Update the `Student` model with the following code:

```
using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;

namespace ContosoUniversity.Models
{
    public class Student
    {
        public int ID { get; set; }
        [StringLength(50)]
        public string LastName { get; set; }
        [StringLength(50, ErrorMessage = "First name cannot be longer than 50 characters.")]  
        public string FirstMidName { get; set; }
        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        public DateTime EnrollmentDate { get; set; }

        public ICollection<Enrollment> Enrollments { get; set; }
    }
}
```

The preceding code limits names to no more than 50 characters. The `StringLength` attribute doesn't prevent a user from entering white space for a name. The `RegularExpression` attribute is used to apply restrictions to the input. For example, the following code requires the first character to be upper case and the remaining characters to be alphabetical:

```
[RegularExpression(@"^([A-Z][a-zA-Z\s-]*$)")]
```

Run the app:

- Navigate to the Students page.
- Select **Create New**, and enter a name longer than 50 characters.
- Select **Create**, client-side validation shows an error message.

In **SQL Server Object Explorer** (SSOX), open the Student table designer by double-clicking the **Student** table.

The screenshot shows the "dbo.Student [Design]" table in SQL Server Object Explorer. The table has four columns: "ID" (int, primary key, clustered), "EnrollmentDate" (datetime2(7)), "FirstMidName" (nvarchar(MAX), nullable), and "LastName" (nvarchar(MAX), nullable). The "T-SQL" tab displays the following CREATE TABLE script:

```
CREATE TABLE [dbo].[Student] (
    [ID] INT IDENTITY (1, 1) NOT NULL,
    [EnrollmentDate] DATETIME2 (7) NOT NULL,
    [FirstMidName] NVARCHAR (MAX) NULL,
    [LastName] NVARCHAR (MAX) NULL,
    CONSTRAINT [PK_Student] PRIMARY KEY CLUSTERED ([ID] ASC)
);
```

The preceding image shows the schema for the `Student` table. The name fields have type `nvarchar(MAX)` because migrations has not been run on the DB. When migrations are run later in this tutorial, the name fields become

```
nvarchar(50) .
```

## The Column attribute

Attributes can control how classes and properties are mapped to the database. In this section, the `Column` attribute is used to map the name of the `FirstMidName` property to "FirstName" in the DB.

When the DB is created, property names on the model are used for column names (except when the `Column` attribute is used).

The `student` model uses `FirstMidName` for the first-name field because the field might also contain a middle name.

Update the `Student.cs` file with the following highlighted code:

```
using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Student
    {
        public int ID { get; set; }
        [StringLength(50)]
        public string LastName { get; set; }
        [StringLength(50, ErrorMessage = "First name cannot be longer than 50 characters.")]  
[Column("FirstName")]
        public string FirstMidName { get; set; }
        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        public DateTime EnrollmentDate { get; set; }

        public ICollection<Enrollment> Enrollments { get; set; }
    }
}
```

With the preceding change, `Student.FirstMidName` in the app maps to the `FirstName` column of the `Student` table.

The addition of the `Column` attribute changes the model backing the `SchoolContext`. The model backing the `SchoolContext` no longer matches the database. If the app is run before applying migrations, the following exception is generated:

```
SqlException: Invalid column name 'FirstName'.
```

To update the DB:

- Build the project.
- Open a command window in the project folder. Enter the following commands to create a new migration and update the DB:
  - [Visual Studio](#)
  - [.NET Core CLI](#)

```
Add-Migration ColumnFirstName  
Update-Database
```

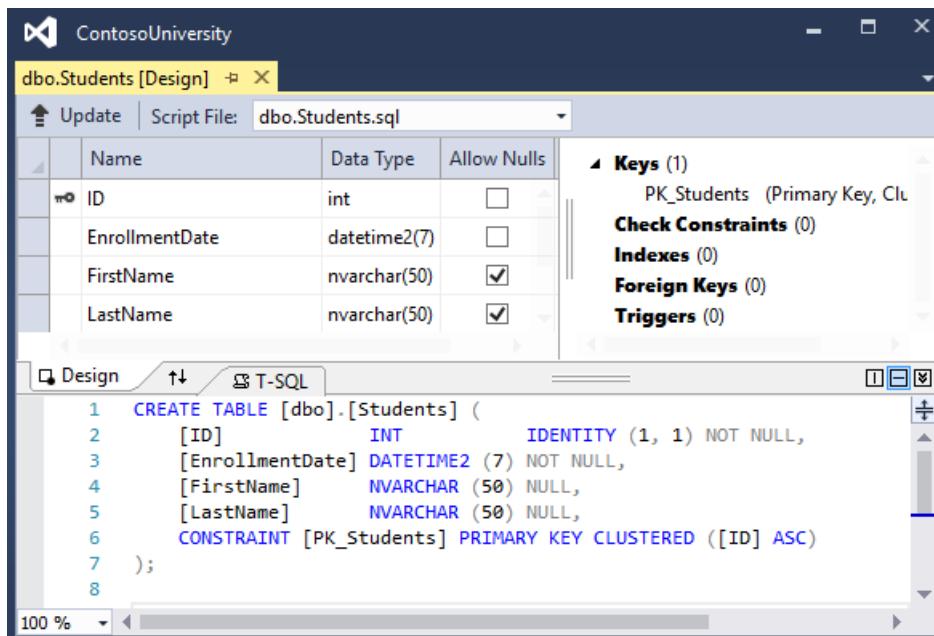

The `migrations add ColumnFirstName` command generates the following warning message:

An operation was scaffolded that may result in the loss of data.  
Please review the migration for accuracy.

The warning is generated because the name fields are now limited to 50 characters. If a name in the DB had more than 50 characters, the 51 to last character would be lost.

- Test the app.

Open the Student table in SSOX:

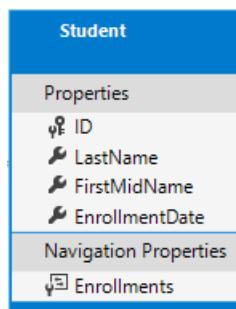

Before migration was applied, the name columns were of type `nvarchar(MAX)`. The name columns are now `nvarchar(50)`. The column name has changed from `FirstMidName` to `FirstName`.

#### NOTE

In the following section, building the app at some stages generates compiler errors. The instructions specify when to build the app.

## Student entity update

Update `Models/Student.cs` with the following code:

```

using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Student
    {
        public int ID { get; set; }
        [Required]
        [StringLength(50)]
        [Display(Name = "Last Name")]
        public string LastName { get; set; }
        [Required]
        [StringLength(50, ErrorMessage = "First name cannot be longer than 50 characters.")]
        [Column("FirstName")]
        [Display(Name = "First Name")]
        public string FirstMidName { get; set; }
        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        [Display(Name = "Enrollment Date")]
        public DateTime EnrollmentDate { get; set; }
        [Display(Name = "Full Name")]
        public string FullName
        {
            get
            {
                return LastName + ", " + FirstMidName;
            }
        }

        public ICollection<Enrollment> Enrollments { get; set; }
    }
}

```

## The Required attribute

The `Required` attribute makes the name properties required fields. The `Required` attribute isn't needed for non-nullable types such as value types (`DateTime`, `int`, `double`, etc.). Types that can't be null are automatically treated as required fields.

The `Required` attribute could be replaced with a minimum length parameter in the `StringLength` attribute:

```

[Display(Name = "Last Name")]
[StringLength(50, MinimumLength=1)]
public string LastName { get; set; }

```

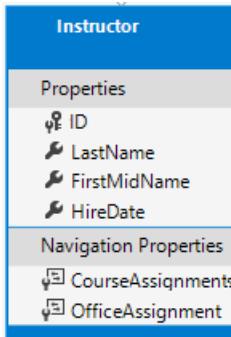

## The Display attribute

The `Display` attribute specifies that the caption for the text boxes should be "First Name", "Last Name", "Full Name", and "Enrollment Date." The default captions had no space dividing the words, for example "Lastname."

## The FullName calculated property

`FullName` is a calculated property that returns a value that's created by concatenating two other properties. `FullName` cannot be set, it has only a get accessor. No `FullName` column is created in the database.

# Create the Instructor Entity

Create `Models/Instructor.cs` with the following code:

```
using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Instructor
    {
        public int ID { get; set; }

        [Required]
        [Display(Name = "Last Name")]
        [StringLength(50)]
        public string LastName { get; set; }

        [Required]
        [Column("FirstName")]
        [Display(Name = "First Name")]
        [StringLength(50)]
        public string FirstMidName { get; set; }

        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        [Display(Name = "Hire Date")]
        public DateTime HireDate { get; set; }

        [Display(Name = "Full Name")]
        public string FullName
        {
            get { return LastName + ", " + FirstMidName; }
        }

        public ICollection<CourseAssignment> CourseAssignments { get; set; }
        public OfficeAssignment OfficeAssignment { get; set; }
    }
}
```

Multiple attributes can be on one line. The `HireDate` attributes could be written as follows:

```
[DataType(DataType.Date), Display(Name = "Hire Date"), DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
```

## The `CourseAssignments` and `OfficeAssignment` navigation properties

The `CourseAssignments` and `OfficeAssignment` properties are navigation properties.

An instructor can teach any number of courses, so `CourseAssignments` is defined as a collection.

```
public ICollection<CourseAssignment> CourseAssignments { get; set; }
```

If a navigation property holds multiple entities:

- It must be a list type where the entries can be added, deleted, and updated.

Navigation property types include:

- `ICollection<T>`
- `List<T>`
- `HashSet<T>`

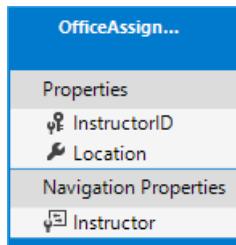

If `ICollection<T>` is specified, EF Core creates a `HashSet<T>` collection by default.

The `CourseAssignment` entity is explained in the section on many-to-many relationships.

Contoso University business rules state that an instructor can have at most one office. The `OfficeAssignment` property holds a single `OfficeAssignment` entity. `OfficeAssignment` is null if no office is assigned.

```
public OfficeAssignment OfficeAssignment { get; set; }
```

## Create the OfficeAssignment entity

Create `Models/OfficeAssignment.cs` with the following code:

```
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class OfficeAssignment
    {
        [Key]
        public int InstructorID { get; set; }
        [StringLength(50)]
        [Display(Name = "Office Location")]
        public string Location { get; set; }

        public Instructor Instructor { get; set; }
    }
}
```

### The Key attribute

The `[Key]` attribute is used to identify a property as the primary key (PK) when the property name is something other than `classnameID` or `ID`.

There's a one-to-zero-or-one relationship between the `Instructor` and `OfficeAssignment` entities. An office assignment only exists in relation to the instructor it's assigned to. The `OfficeAssignment` PK is also its foreign key

(FK) to the `Instructor` entity. EF Core can't automatically recognize `InstructorID` as the PK of `OfficeAssignment` because:

- `InstructorID` doesn't follow the ID or `classnameID` naming convention.

Therefore, the `key` attribute is used to identify `InstructorID` as the PK:

```
[Key]  
public int InstructorID { get; set; }
```

By default, EF Core treats the key as non-database-generated because the column is for an identifying relationship.

### The Instructor navigation property

The `OfficeAssignment` navigation property for the `Instructor` entity is nullable because:

- Reference types (such as classes) are nullable.
- An instructor might not have an office assignment.

The `OfficeAssignment` entity has a non-nullable `Instructor` navigation property because:

- `InstructorID` is non-nullable.
- An office assignment can't exist without an instructor.

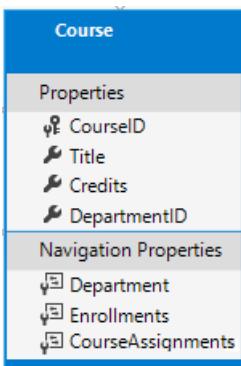

When an `Instructor` entity has a related `OfficeAssignment` entity, each entity has a reference to the other one in its navigation property.

The `[Required]` attribute could be applied to the `Instructor` navigation property:

```
[Required]  
public Instructor Instructor { get; set; }
```

The preceding code specifies that there must be a related instructor. The preceding code is unnecessary because the `InstructorID` foreign key (which is also the PK) is non-nullable.

## Modify the Course Entity

Update `Models/Course.cs` with the following code:

```

using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Course
    {
        [DatabaseGenerated(DatabaseGeneratedOption.None)]
        [Display(Name = "Number")]
        public int CourseID { get; set; }

        [StringLength(50, MinimumLength = 3)]
        public string Title { get; set; }

        [Range(0, 5)]
        public int Credits { get; set; }

        public int DepartmentID { get; set; }

        public Department Department { get; set; }
        public ICollection<Enrollment> Enrollments { get; set; }
        public ICollection<CourseAssignment> CourseAssignments { get; set; }
    }
}

```

The `Course` entity has a foreign key (FK) property `DepartmentID`. `DepartmentID` points to the related `Department` entity. The `Course` entity has a `Department` navigation property.

EF Core doesn't require a FK property for a data model when the model has a navigation property for a related entity.

EF Core automatically creates FKs in the database wherever they're needed. EF Core creates [shadow properties](#) for automatically created FKs. Having the FK in the data model can make updates simpler and more efficient. For example, consider a model where the FK property `DepartmentID` is *not* included. When a course entity is fetched to edit:

- The `Department` entity is null if it's not explicitly loaded.
- To update the course entity, the `Department` entity must first be fetched.

When the FK property `DepartmentID` is included in the data model, there's no need to fetch the `Department` entity before an update.

### The `DatabaseGenerated` attribute

The `[DatabaseGenerated(DatabaseGeneratedOption.None)]` attribute specifies that the PK is provided by the application rather than generated by the database.

```

[DatabaseGenerated(DatabaseGeneratedOption.None)]
[Display(Name = "Number")]
public int CourseID { get; set; }

```

By default, EF Core assumes that PK values are generated by the DB. DB generated PK values is generally the best approach. For `course` entities, the user specifies the PK. For example, a course number such as a 1000 series for the math department, a 2000 series for the English department.

The `DatabaseGenerated` attribute can also be used to generate default values. For example, the DB can automatically generate a date field to record the date a row was created or updated. For more information, see [Generated Properties](#).

## Foreign key and navigation properties

The foreign key (FK) properties and navigation properties in the `course` entity reflect the following relationships:

A course is assigned to one department, so there's a `DepartmentID` FK and a `Department` navigation property.

```
public int DepartmentID { get; set; }
public Department Department { get; set; }
```

A course can have any number of students enrolled in it, so the `Enrollments` navigation property is a collection:

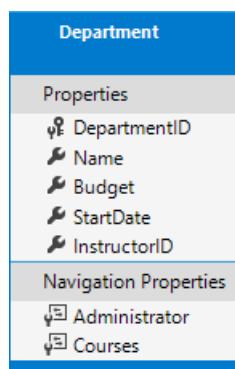

```
public ICollection<Enrollment> Enrollments { get; set; }
```

A course may be taught by multiple instructors, so the `CourseAssignments` navigation property is a collection:

```
public ICollection<CourseAssignment> CourseAssignments { get; set; }
```

`CourseAssignment` is explained [later](#).

## Create the Department entity

Create `Models/Department.cs` with the following code:

```

using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Department
    {
        public int DepartmentID { get; set; }

        [StringLength(50, MinimumLength = 3)]
        public string Name { get; set; }

        [DataType(DataType.Currency)]
        [Column(TypeName = "money")]
        public decimal Budget { get; set; }

        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        [Display(Name = "Start Date")]
        public DateTime StartDate { get; set; }

        public int? InstructorID { get; set; }

        public Instructor Administrator { get; set; }
        public ICollection<Course> Courses { get; set; }
    }
}

```

## The Column attribute

Previously the `Column` attribute was used to change column name mapping. In the code for the `Department` entity, the `Column` attribute is used to change SQL data type mapping. The `Budget` column is defined using the SQL Server money type in the DB:

```

[Column(TypeName="money")]
public decimal Budget { get; set; }

```

Column mapping is generally not required. EF Core generally chooses the appropriate SQL Server data type based on the CLR type for the property. The CLR `decimal` type maps to a SQL Server `decimal` type. `Budget` is for currency, and the money data type is more appropriate for currency.

## Foreign key and navigation properties

The FK and navigation properties reflect the following relationships:

- A department may or may not have an administrator.
- An administrator is always an instructor. Therefore the `InstructorID` property is included as the FK to the `Instructor` entity.

The navigation property is named `Administrator` but holds an `Instructor` entity:

```

public int? InstructorID { get; set; }
public Instructor Administrator { get; set; }

```

The question mark (?) in the preceding code specifies the property is nullable.

A department may have many courses, so there's a `Courses` navigation property:

```
public ICollection<Course> Courses { get; set; }
```

Note: By convention, EF Core enables cascade delete for non-nullable FKs and for many-to-many relationships. Cascading delete can result in circular cascade delete rules. Circular cascade delete rules causes an exception when a migration is added.

For example, if the `Department.InstructorID` property wasn't defined as nullable:

- EF Core configures a cascade delete rule to delete the instructor when the department is deleted.
- Deleting the instructor when the department is deleted isn't the intended behavior.

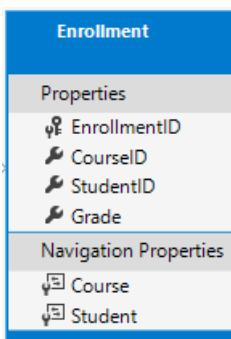

If business rules required the `InstructorID` property be non-nullable, use the following fluent API statement:

```
modelBuilder.Entity<Department>()
    .HasOne(d => d.Administrator)
    .WithMany()
    .OnDelete(DeleteBehavior.Restrict)
```

The preceding code disables cascade delete on the department-instructor relationship.

## Update the Enrollment entity

An enrollment record is for a one course taken by one student.

Update `Models/Enrollment.cs` with the following code:

```
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public enum Grade
    {
        A, B, C, D, F
    }

    public class Enrollment
    {
        public int EnrollmentID { get; set; }
        public int CourseID { get; set; }
        public int StudentID { get; set; }
        [DisplayFormat(NullDisplayText = "No grade")]
        public Grade? Grade { get; set; }

        public Course Course { get; set; }
        public Student Student { get; set; }
    }
}
```

## Foreign key and navigation properties

The FK properties and navigation properties reflect the following relationships:

An enrollment record is for one course, so there's a `CourseID` FK property and a `Course` navigation property:

```
public int CourseID { get; set; }
public Course Course { get; set; }
```

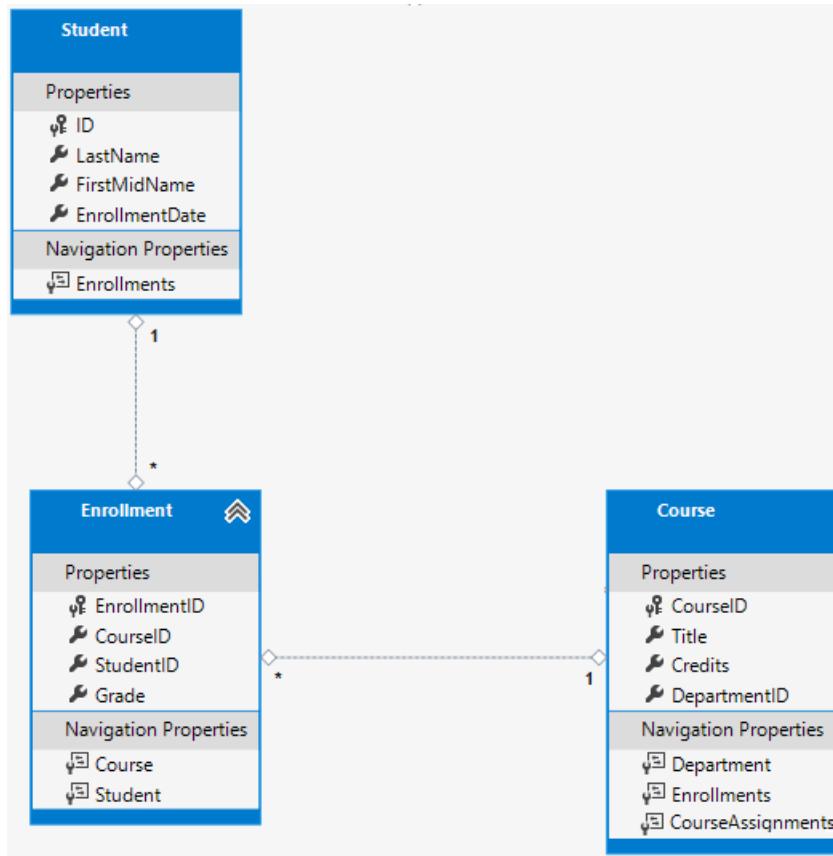

An enrollment record is for one student, so there's a `StudentID` FK property and a `Student` navigation property:

```
public int StudentID { get; set; }
public Student Student { get; set; }
```

## Many-to-Many Relationships

There's a many-to-many relationship between the `Student` and `Course` entities. The `Enrollment` entity functions as a many-to-many join table *with payload* in the database. "With payload" means that the `Enrollment` table contains additional data besides FKS for the joined tables (in this case, the PK and `Grade`).

The following illustration shows what these relationships look like in an entity diagram. (This diagram was generated using EF Power Tools for EF 6.x. Creating the diagram isn't part of the tutorial.)

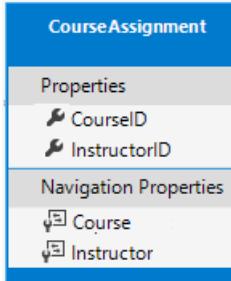

Each relationship line has a 1 at one end and an asterisk (\*) at the other, indicating a one-to-many relationship.

If the `Enrollment` table didn't include grade information, it would only need to contain the two FKS (`CourseID` and `StudentID`). A many-to-many join table without payload is sometimes called a pure join table (PJT).

The `Instructor` and `Course` entities have a many-to-many relationship using a pure join table.

Note: EF 6.x supports implicit join tables for many-to-many relationships, but EF Core doesn't. For more information, see [Many-to-many relationships in EF Core 2.0](#).

# The CourseAssignment entity

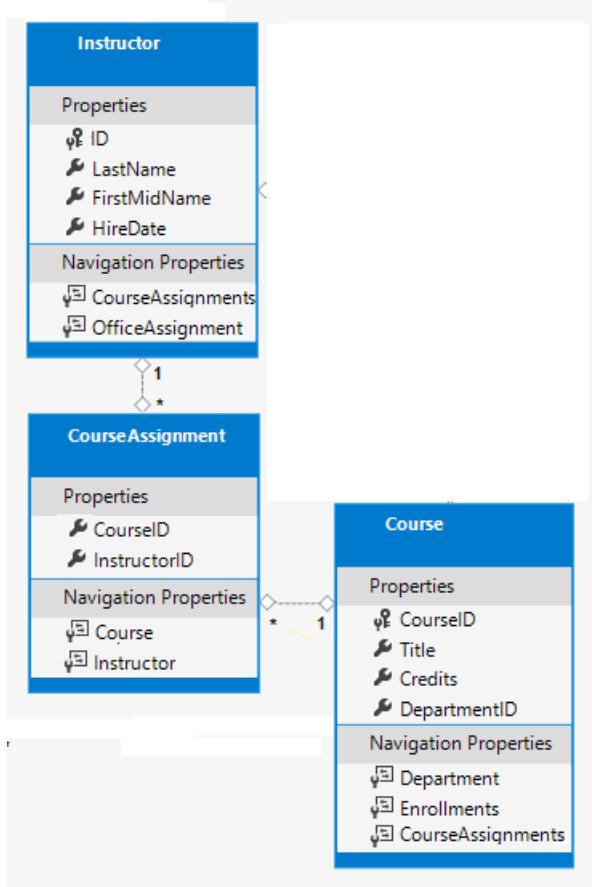

Create `Models/CourseAssignment.cs` with the following code:

```
using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class CourseAssignment
    {
        public int InstructorID { get; set; }
        public int CourseID { get; set; }
        public Instructor Instructor { get; set; }
        public Course Course { get; set; }
    }
}
```

## Instructor-to-Courses

The Instructor-to-Courses many-to-many relationship:

- Requires a join table that must be represented by an entity set.

- Is a pure join table (table without payload).

It's common to name a join entity `EntityName1EntityName2`. For example, the Instructor-to-Courses join table using this pattern is `CourseInstructor`. However, we recommend using a name that describes the relationship.

Data models start out simple and grow. No-payload joins (PJs) frequently evolve to include payload. By starting with a descriptive entity name, the name doesn't need to change when the join table changes. Ideally, the join entity would have its own natural (possibly single word) name in the business domain. For example, Books and Customers could be linked with a join entity called Ratings. For the Instructor-to-Courses many-to-many relationship, `CourseAssignment` is preferred over `CourseInstructor`.

### Composite key

FKs are not nullable. The two FKs in `CourseAssignment` (`InstructorID` and `CourseID`) together uniquely identify each row of the `CourseAssignment` table. `CourseAssignment` doesn't require a dedicated PK. The `InstructorID` and `CourseID` properties function as a composite PK. The only way to specify composite PKs to EF Core is with the *fluent API*. The next section shows how to configure the composite PK.

The composite key ensures:

- Multiple rows are allowed for one course.
- Multiple rows are allowed for one instructor.
- Multiple rows for the same instructor and course isn't allowed.

The `Enrollment` join entity defines its own PK, so duplicates of this sort are possible. To prevent such duplicates:

- Add a unique index on the FK fields, or
- Configure `Enrollment` with a primary composite key similar to `CourseAssignment`. For more information, see [Indexes](#).

## Update the DB context

Add the following highlighted code to `Data/SchoolContext.cs`:

```

using ContosoUniversity.Models;
using Microsoft.EntityFrameworkCore;

namespace ContosoUniversity.Models
{
    public class SchoolContext : DbContext
    {
        public SchoolContext(DbContextOptions<SchoolContext> options) : base(options)
        {

        }

        public DbSet<Course> Courses { get; set; }
        public DbSet<Enrollment> Enrollment { get; set; }
        public DbSet<Student> Student { get; set; }
        public DbSet<Department> Departments { get; set; }
        public DbSet<Instructor> Instructors { get; set; }
        public DbSet<OfficeAssignment> OfficeAssignments { get; set; }
        public DbSet<CourseAssignment> CourseAssignments { get; set; }

        protected override void OnModelCreating(ModelBuilder modelBuilder)
        {
            modelBuilder.Entity<Course>().ToTable("Course");
            modelBuilder.Entity<Enrollment>().ToTable("Enrollment");
            modelBuilder.Entity<Student>().ToTable("Student");
            modelBuilder.Entity<Department>().ToTable("Department");
            modelBuilder.Entity<Instructor>().ToTable("Instructor");
            modelBuilder.Entity<OfficeAssignment>().ToTable("OfficeAssignment");
            modelBuilder.Entity<CourseAssignment>().ToTable("CourseAssignment");

            modelBuilder.Entity<CourseAssignment>()
                .HasKey(c => new { c.CourseID, c.InstructorID });
        }
    }
}

```

The preceding code adds the new entities and configures the `CourseAssignment` entity's composite PK.

## Fluent API alternative to attributes

The `OnModelCreating` method in the preceding code uses the *fluent API* to configure EF Core behavior. The API is called "fluent" because it's often used by stringing a series of method calls together into a single statement. The [following code](#) is an example of the fluent API:

```

protected override void OnModelCreating(ModelBuilder modelBuilder)
{
    modelBuilder.Entity<Blog>()
        .Property(b => b.Url)
        .IsRequired();
}

```

In this tutorial, the fluent API is used only for DB mapping that can't be done with attributes. However, the fluent API can specify most of the formatting, validation, and mapping rules that can be done with attributes.

Some attributes such as `MinimumLength` can't be applied with the fluent API. `MinimumLength` doesn't change the schema, it only applies a minimum length validation rule.

Some developers prefer to use the fluent API exclusively so that they can keep their entity classes "clean." Attributes and the fluent API can be mixed. There are some configurations that can only be done with the fluent API (specifying a composite PK). There are some configurations that can only be done with attributes (`MinimumLength`). The recommended practice for using fluent API or attributes:

- Choose one of these two approaches.
- Use the chosen approach consistently as much as possible.

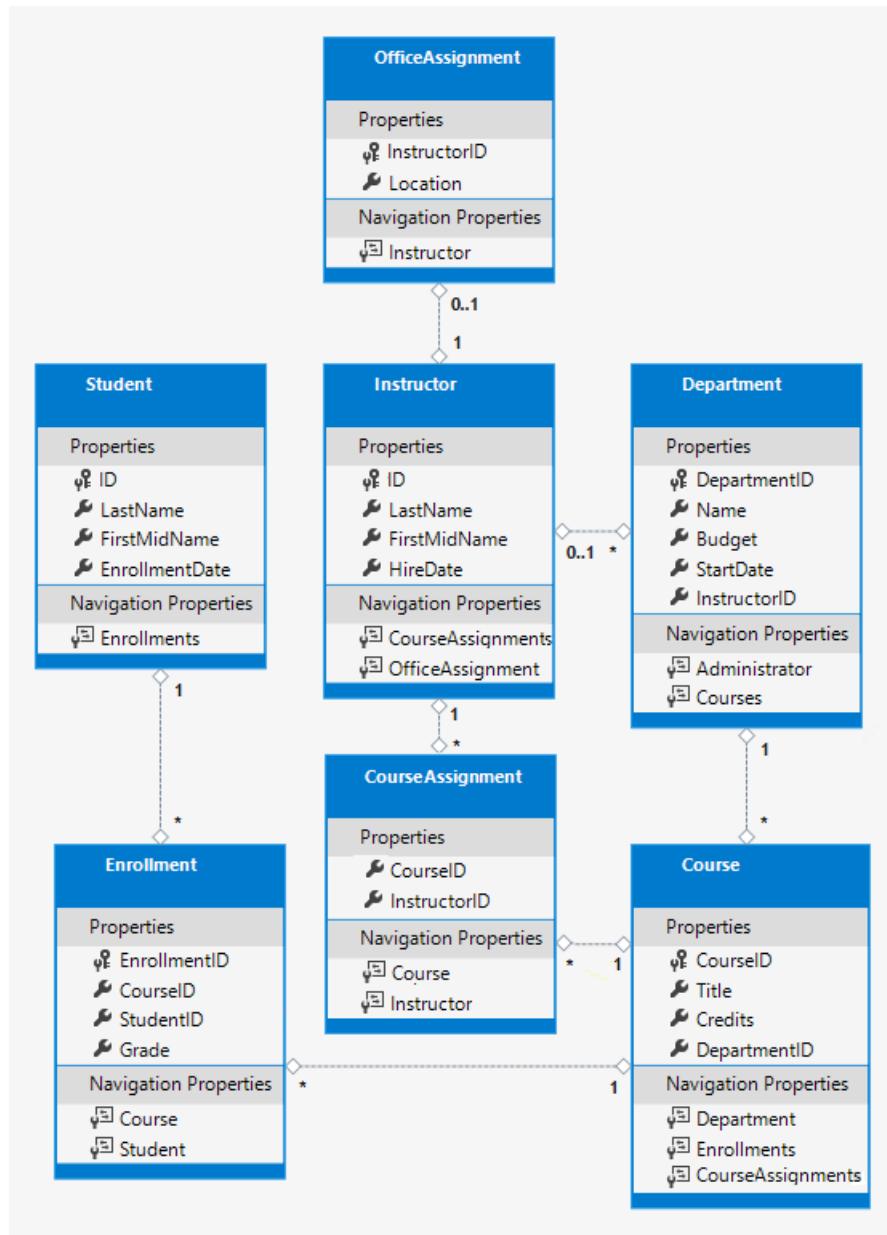

Some of the attributes used in the this tutorial are used for:

- Validation only (for example, `MinimumLength` ).
- EF Core configuration only (for example, `HasKey` ).
- Validation and EF Core configuration (for example, `[StringLength(50)]` ).

For more information about attributes vs. fluent API, see [Methods of configuration](#).

## Entity Diagram Showing Relationships

The following illustration shows the diagram that EF Power Tools create for the completed School model.

The preceding diagram shows:

- Several one-to-many relationship lines (1 to \*).
- The one-to-zero-or-one relationship line (1 to 0..1) between the `Instructor` and `OfficeAssignment` entities.
- The zero-or-one-to-many relationship line (0..1 to \*) between the `Instructor` and `Department` entities.

## Seed the DB with Test Data

Update the code in *Data/DbInitializer.cs*:

```
using System;
using System.Linq;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using ContosoUniversity.Models;

namespace ContosoUniversity.Data
{
    public static class DbInitializer
    {
        public static void Initialize(SchoolContext context)
        {
            //context.Database.EnsureCreated();

            // Look for any students.
            if (context.Student.Any())
            {
                return; // DB has been seeded
            }

            var students = new Student[]
            {
                new Student { FirstMidName = "Carson", LastName = "Alexander",
                    EnrollmentDate = DateTime.Parse("2010-09-01") },
                new Student { FirstMidName = "Meredith", LastName = "Alonso",
                    EnrollmentDate = DateTime.Parse("2012-09-01") },
                new Student { FirstMidName = "Arturo", LastName = "Anand",
                    EnrollmentDate = DateTime.Parse("2013-09-01") },
                new Student { FirstMidName = "Gytis", LastName = "Barzdukas",
                    EnrollmentDate = DateTime.Parse("2012-09-01") },
                new Student { FirstMidName = "Yan", LastName = "Li",
                    EnrollmentDate = DateTime.Parse("2012-09-01") },
                new Student { FirstMidName = "Peggy", LastName = "Justice",
                    EnrollmentDate = DateTime.Parse("2011-09-01") },
                new Student { FirstMidName = "Laura", LastName = "Norman",
                    EnrollmentDate = DateTime.Parse("2013-09-01") },
                new Student { FirstMidName = "Nino", LastName = "Olivetto",
                    EnrollmentDate = DateTime.Parse("2005-09-01") }
            };

            foreach (Student s in students)
            {
                context.Student.Add(s);
            }
            context.SaveChanges();

            var instructors = new Instructor[]
            {
                new Instructor { FirstMidName = "Kim", LastName = "Abercrombie",
                    HireDate = DateTime.Parse("1995-03-11") },
                new Instructor { FirstMidName = "Fadi", LastName = "Fakhouri",
                    HireDate = DateTime.Parse("2002-07-06") },
                new Instructor { FirstMidName = "Roger", LastName = "Harui",
                    HireDate = DateTime.Parse("1998-07-01") },
                new Instructor { FirstMidName = "Candace", LastName = "Kapoor",
                    HireDate = DateTime.Parse("2001-01-15") },
                new Instructor { FirstMidName = "Roger", LastName = "Zheng",
                    HireDate = DateTime.Parse("2004-02-12") }
            };

            foreach (Instructor i in instructors)
            {
                context.Instructors.Add(i);
            }
        }
    }
}
```

```

        }

        context.SaveChanges();

        var departments = new Department[]
        {
            new Department { Name = "English",      Budget = 350000,
                StartDate = DateTime.Parse("2007-09-01"),
                InstructorID = instructors.Single( i => i.LastName == "Abercrombie").ID },
            new Department { Name = "Mathematics",   Budget = 100000,
                StartDate = DateTime.Parse("2007-09-01"),
                InstructorID = instructors.Single( i => i.LastName == "Fakhouri").ID },
            new Department { Name = "Engineering",   Budget = 350000,
                StartDate = DateTime.Parse("2007-09-01"),
                InstructorID = instructors.Single( i => i.LastName == "Harui").ID },
            new Department { Name = "Economics",     Budget = 100000,
                StartDate = DateTime.Parse("2007-09-01"),
                InstructorID = instructors.Single( i => i.LastName == "Kapoor").ID }
        };

        foreach (Department d in departments)
        {
            context.Departments.Add(d);
        }
        context.SaveChanges();

        var courses = new Course[]
        {
            new Course {CourseID = 1050, Title = "Chemistry",      Credits = 3,
                DepartmentID = departments.Single( s => s.Name == "Engineering").DepartmentID
            },
            new Course {CourseID = 4022, Title = "Microeconomics", Credits = 3,
                DepartmentID = departments.Single( s => s.Name == "Economics").DepartmentID
            },
            new Course {CourseID = 4041, Title = "Macroeconomics", Credits = 3,
                DepartmentID = departments.Single( s => s.Name == "Economics").DepartmentID
            },
            new Course {CourseID = 1045, Title = "Calculus",       Credits = 4,
                DepartmentID = departments.Single( s => s.Name == "Mathematics").DepartmentID
            },
            new Course {CourseID = 3141, Title = "Trigonometry",   Credits = 4,
                DepartmentID = departments.Single( s => s.Name == "Mathematics").DepartmentID
            },
            new Course {CourseID = 2021, Title = "Composition",    Credits = 3,
                DepartmentID = departments.Single( s => s.Name == "English").DepartmentID
            },
            new Course {CourseID = 2042, Title = "Literature",     Credits = 4,
                DepartmentID = departments.Single( s => s.Name == "English").DepartmentID
            },
        };

        foreach (Course c in courses)
        {
            context.Courses.Add(c);
        }
        context.SaveChanges();

        var officeAssignments = new OfficeAssignment[]
        {
            new OfficeAssignment {
                InstructorID = instructors.Single( i => i.LastName == "Fakhouri").ID,
                Location = "Smith 17" },
            new OfficeAssignment {
                InstructorID = instructors.Single( i => i.LastName == "Harui").ID,
                Location = "Gowan 27" },
            new OfficeAssignment {
                InstructorID = instructors.Single( i => i.LastName == "Kapoor").ID,
                Location = "Thompson 304" },
        };
    }
}

```

```

foreach (OfficeAssignment o in officeAssignments)
{
    context.OfficeAssignments.Add(o);
}
context.SaveChanges();

var courseInstructors = new CourseAssignment[]
{
    new CourseAssignment {
        CourseID = courses.Single(c => c.Title == "Chemistry" ).CourseID,
        InstructorID = instructors.Single(i => i.LastName == "Kapoor").ID
    },
    new CourseAssignment {
        CourseID = courses.Single(c => c.Title == "Chemistry" ).CourseID,
        InstructorID = instructors.Single(i => i.LastName == "Harui").ID
    },
    new CourseAssignment {
        CourseID = courses.Single(c => c.Title == "Microeconomics" ).CourseID,
        InstructorID = instructors.Single(i => i.LastName == "Zheng").ID
    },
    new CourseAssignment {
        CourseID = courses.Single(c => c.Title == "Macroeconomics" ).CourseID,
        InstructorID = instructors.Single(i => i.LastName == "Zheng").ID
    },
    new CourseAssignment {
        CourseID = courses.Single(c => c.Title == "Calculus" ).CourseID,
        InstructorID = instructors.Single(i => i.LastName == "Fakhouri").ID
    },
    new CourseAssignment {
        CourseID = courses.Single(c => c.Title == "Trigonometry" ).CourseID,
        InstructorID = instructors.Single(i => i.LastName == "Harui").ID
    },
    new CourseAssignment {
        CourseID = courses.Single(c => c.Title == "Composition" ).CourseID,
        InstructorID = instructors.Single(i => i.LastName == "Abercrombie").ID
    },
    new CourseAssignment {
        CourseID = courses.Single(c => c.Title == "Literature" ).CourseID,
        InstructorID = instructors.Single(i => i.LastName == "Abercrombie").ID
    },
},
};

foreach (CourseAssignment ci in courseInstructors)
{
    context.CourseAssignments.Add(ci);
}
context.SaveChanges();

var enrollments = new Enrollment[]
{
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Alexander").ID,
        CourseID = courses.Single(c => c.Title == "Chemistry" ).CourseID,
        Grade = Grade.A
    },
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Alexander").ID,
        CourseID = courses.Single(c => c.Title == "Microeconomics" ).CourseID,
        Grade = Grade.C
    },
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Alexander").ID,
        CourseID = courses.Single(c => c.Title == "Macroeconomics" ).CourseID,
        Grade = Grade.B
    },
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Alonso").ID,
        CourseID = courses.Single(c => c.Title == "Calculus" ).CourseID,
        Grade = Grade.B
    }
};

```

The preceding code provides seed data for the new entities. Most of this code creates new entity objects and loads sample data. The sample data is used for testing. The preceding code creates the following many-to-many relationships:

- Enrollments
  - CourseAssignment

Note: EF Core 2.1 will support data seeding.

## Add a migration

Build the project.

- [Visual Studio](#)
- [.NET Core CLI](#)

```
Add-Migration ComplexDataModel
```

The preceding command displays a warning about possible data loss.

```
An operation was scaffolded that may result in the loss of data.  
Please review the migration for accuracy.  
Done. To undo this action, use 'ef migrations remove'
```

If the `database update` command is run, the following error is produced:

```
The ALTER TABLE statement conflicted with the FOREIGN KEY constraint  
"FK_dbo.Course_dbo.Department_DepartmentID". The conflict occurred in  
database "ContosoUniversity", table "dbo.Department", column 'DepartmentID'.
```

When migrations are run with existing data, there may be FK constraints that are not satisfied with the exiting data. For this tutorial, a new DB is created, so there are no FK constraint violations. See [Fixing foreign key constraints with legacy data](#) for instructions on how to fix the FK violations on the current DB.

### Drop and update the database

The code in the updated `DbInitializer` adds seed data for the new entities. To force EF Core to create a new DB, drop and update the DB:

- [Visual Studio](#)
- [.NET Core CLI](#)

In the **Package Manager Console** (PMC), run the following command:

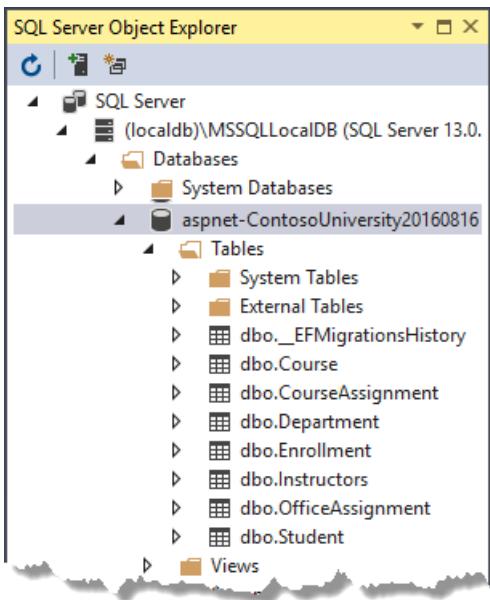

```
Drop-Database  
Update-Database
```

Run `Get-Help about_EntityFrameworkCore` from the PMC to get help information.

Run the app. Running the app runs the `DbInitializer.Initialize` method. The `DbInitializer.Initialize` populates the new DB.

Open the DB in SSOX:

- If SSOX was opened previously, click the **Refresh** button.
- Expand the **Tables** node. The created tables are displayed.

Examine the **CourseAssignment** table:

- Right-click the **CourseAssignment** table and select **View Data**.
- Verify the **CourseAssignment** table contains data.

	CourseID	InstructorID
▶	2021	1
	2042	1
	1045	2
	1050	3
	3141	3
	1050	4
	4022	5
	4041	5
★	NULL	NULL

## Fixing foreign key constraints with legacy data

This section is optional.

When migrations are run with existing data, there may be FK constraints that are not satisfied with the exiting data. With production data, steps must be taken to migrate the existing data. This section provides an example of fixing FK constraint violations. Don't make these code changes without a backup. Don't make these code changes if you completed the previous section and updated the database.

The `{timestamp}_ComplexDataModel.cs` file contains the following code:

```
migrationBuilder.AddColumn<int>(
    name: "DepartmentID",
    table: "Course",
    type: "int",
    nullable: false,
    defaultValue: 0);
```

The preceding code adds a non-nullable `DepartmentID` FK to the `course` table. The DB from the previous tutorial contains rows in `Course`, so that table cannot be updated by migrations.

To make the `ComplexDataModel` migration work with existing data:

- Change the code to give the new column (`DepartmentID`) a default value.
- Create a fake department named "Temp" to act as the default department.

### Fix the foreign key constraints

Update the `ComplexDataModel` classes `Up` method:

- Open the `{timestamp}_ComplexDataModel.cs` file.
- Comment out the line of code that adds the `DepartmentID` column to the `Course` table.

```
migrationBuilder.AlterColumn<string>(
    name: "Title",
    table: "Course",
    maxLength: 50,
    nullable: true,
    oldClrType: typeof(string),
    oldNullable: true);

//migrationBuilder.AddColumn<int>(
//    name: "DepartmentID",
//    table: "Course",
//    nullable: false,
//    defaultValue: 0);
```

Add the following highlighted code. The new code goes after the `.CreateTable( name: "Department" )` block:

```
migrationBuilder.CreateTable(
    name: "Department",
    columns: table => new
    {
        DepartmentID = table.Column<int>(type: "int", nullable: false)
            .Annotation("SqlServer:ValueGenerationStrategy", SqlServerValueGenerationStrategy.IdentityColumn),
        Budget = table.Column<decimal>(type: "money", nullable: false),
        InstructorID = table.Column<int>(type: "int", nullable: true),
        Name = table.Column<string>(type: "nvarchar(50)", maxLength: 50, nullable: true),
        StartDate = table.Column<DateTime>(type: "datetime2", nullable: false)
    },
    constraints: table =>
    {
        table.PrimaryKey("PK_Department", x => x.DepartmentID);
        table.ForeignKey(
            name: "FK_Department_Instructor_InstructorID",
            column: x => x.InstructorID,
            principalTable: "Instructor",
            principalColumn: "ID",
            onDelete: ReferentialAction.Restrict);
    });
}

migrationBuilder.Sql("INSERT INTO dbo.Department (Name, Budget, StartDate) VALUES ('Temp', 0.00,
GETDATE())");
// Default value for FK points to department created above, with
// defaultValue changed to 1 in following AddColumn statement.

migrationBuilder.AddColumn<int>(
    name: "DepartmentID",
    table: "Course",
    nullable: false,
    defaultValue: 1);
```

With the preceding changes, existing `Course` rows will be related to the "Temp" department after the `ComplexDataModel` `Up` method runs.

A production app would:

- Include code or scripts to add `Department` rows and related `Course` rows to the new `Department` rows.
- Not use the "Temp" department or the default value for `Course.DepartmentID`.

The next tutorial covers related data.

# Razor Pages with EF Core in ASP.NET Core - Read Related Data - 6 of 8

7/14/2018 • 14 minutes to read • [Edit Online](#)

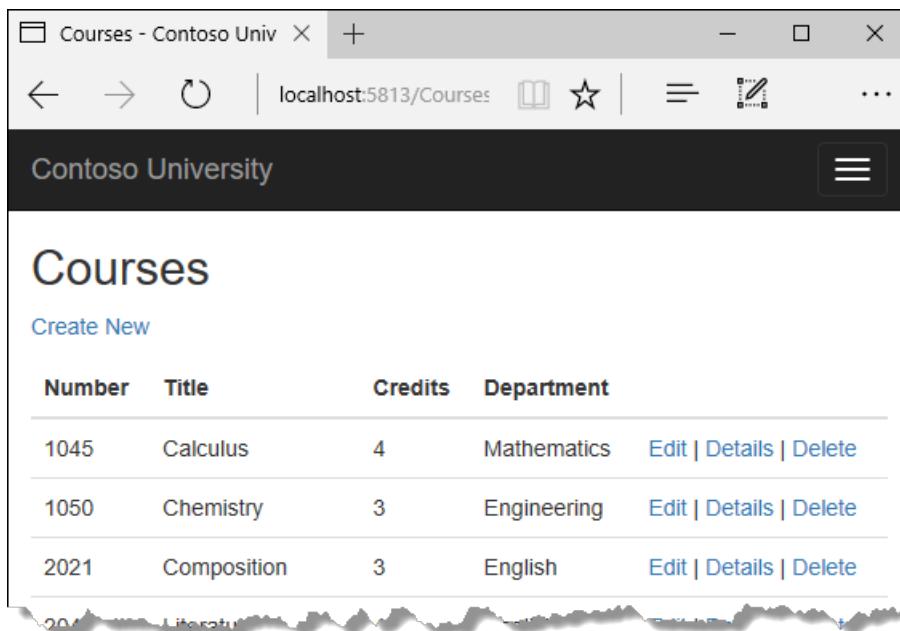

By [Tom Dykstra](#), [Jon P Smith](#), and [Rick Anderson](#)

The Contoso University web app demonstrates how to create Razor Pages web apps using EF Core and Visual Studio. For information about the tutorial series, see [the first tutorial](#).

In this tutorial, related data is read and displayed. Related data is data that EF Core loads into navigation properties.

If you run into problems you can't solve, download the [completed app for this stage](#).

The following illustrations show the completed pages for this tutorial:

A screenshot of a web browser window titled "Courses - Contoso Univ". The address bar shows "localhost:5813/Courses". The page header reads "Contoso University". The main content area is titled "Courses" and contains a table with three rows of course data. The table has columns for "Number", "Title", "Credits", and "Department". Each row includes "Edit | Details | Delete" links. The browser interface includes standard controls like back, forward, and search.

Number	Title	Credits	Department	
1045	Calculus	4	Mathematics	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
1050	Chemistry	3	Engineering	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
2021	Composition	3	English	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

Instructors - Contoso Un X

localhost:1234/Instructors/3?courseID=1050&action=OnGetAsync

## Eager, explicit, and lazy Loading of related data

There are several ways that EF Core can load related data into the navigation properties of an entity:

- **Eager loading.** Eager loading is when a query for one type of entity also loads related entities. When the entity is read, its related data is retrieved. This typically results in a single join query that retrieves all of the data that's needed. EF Core will issue multiple queries for some types of eager loading. Issuing multiple queries can be more efficient than was the case for some queries in EF6 where there was a single query.

Eager loading is specified with the `Include` and `ThenInclude` methods.

```
var departments = _context.Departments.Include(d => d.Courses);
foreach (Department d in departments)
{
    foreach(Course c in d.Courses)
    {
        courseList.Add(d.Name + c.Title);
    }
}
```

Query: all Department entities and related Course entities

Eager loading sends multiple queries when a collection navigation is included:

- One query for the main query
- One query for each collection "edge" in the load tree.
- Separate queries with `Load`: The data can be retrieved in separate queries, and EF Core "fixes up" the navigation properties. "fixes up" means that EF Core automatically populates the navigation properties. Separate queries with `Load` is more like explicit loading than eager loading.

```
var departments = _context.Departments;
foreach (Department d in departments)
{
    _context.Courses.Where(c => c.DepartmentID == d.DepartmentID).Load();
    foreach (Course c in d.Courses)
    {
        courseList.Add(d.Name + c.Title);
    }
}
```

Query: all Department rows

Query: Course rows related to Department d

Note: EF Core automatically fixes up navigation properties to any other entities that were previously loaded into the context instance. Even if the data for a navigation property is *not* explicitly included, the property may still be populated if some or all of the related entities were previously loaded.

- **Explicit loading**. When the entity is first read, related data isn't retrieved. Code must be written to retrieve the related data when it's needed. Explicit loading with separate queries results in multiple queries sent to the DB. With explicit loading, the code specifies the navigation properties to be loaded. Use the `Load` method to do explicit loading. For example:

```
var departments = _context.Departments;
foreach (Department d in departments)
{
    _context.Entry(d).Collection(p => p.Courses).Load();
    foreach (Course c in d.Courses)
    {
        courseList.Add(d.Name + c.Title);
    }
}
```

Query: all Department rows

Query: Course rows related to Department d

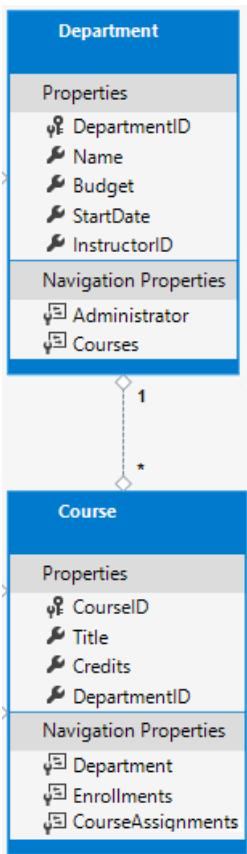

- **Lazy loading**. EF Core doesn't currently support lazy loading. When the entity is first read, related data isn't retrieved. The first time a navigation property is accessed, the data required for that navigation property is automatically retrieved. A query is sent to the DB each time a navigation property is accessed for the first time.
- The `Select` operator loads only the related data needed.

## Create a Courses page that displays department name

The Course entity includes a navigation property that contains the `Department` entity. The `Department` entity contains the department that the course is assigned to.

To display the name of the assigned department in a list of courses:

- Get the `Name` property from the `Department` entity.
- The `Department` entity comes from the `Course.Department` navigation property.

## Scaffold the Course model

- Exit Visual Studio.
- Open a command window in the project directory (The directory that contains the *Program.cs*, *Startup.cs*, and *.csproj* files).
- Run the following command:

```

dotnet add package Microsoft.VisualStudio.Web.CodeGeneration.Design --version 2.1.0
dotnet aspnet-codegenerator razorpage -m Course -dc SchoolContext -udl -outDir Pages\Courses --
referenceScriptLibraries

```

The preceding command scaffolds the **Course** model. Open the project in Visual Studio.

Open *Pages/Courses/Index.cshtml.cs* and examine the `OnGetAsync` method. The scaffolding engine specified eager loading for the `Department` navigation property. The `Include` method specifies eager loading.

Run the app and select the **Courses** link. The department column displays the `DepartmentID`, which isn't useful.

Update the `OnGetAsync` method with the following code:

```

public async Task OnGetAsync()
{
    Course = await _context.Courses
        .Include(c => c.Department)
        .AsNoTracking()
        .ToListAsync();
}

```

The preceding code adds `AsNoTracking`. `AsNoTracking` improves performance because the entities returned are not tracked. The entities are not tracked because they're not updated in the current context.

Update *Pages/Courses/Index.cshtml* with the following highlighted markup:

```

@page
@model ContosoUniversity.Pages.Courses.IndexModel
 @{
     ViewData["Title"] = "Courses";
 }

<h2>Courses</h2>

<p>
    <a asp-page="TestCreate">Create New</a>
</p>
<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.Course[0].CourseID)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Course[0].Title)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Course[0].Credits)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Course[0].Department)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
        @foreach (var item in Model.Course)
        {
            <tr>
                <td>
                    @Html.DisplayFor(modelItem => item.CourseID)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Title)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Credits)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Department.Name)
                </td>
                <td>
                    <a asp-page=".Edit" asp-route-id="@item.CourseID">Edit</a> |
                    <a asp-page=".Details" asp-route-id="@item.CourseID">Details</a> |
                    <a asp-page=".Delete" asp-route-id="@item.CourseID">Delete</a>
                </td>
            </tr>
        }
    </tbody>
</table>

```

The following changes have been made to the scaffolded code:

- Changed the heading from Index to Courses.
- Added a **Number** column that shows the `courseID` property value. By default, primary keys aren't scaffolded because normally they're meaningless to end users. However, in this case the primary key is meaningful.
- Changed the **Department** column to display the department name. The code displays the `Name` property of the `Department` entity that's loaded into the `Department` navigation property:

```
@Html.DisplayFor(modelItem => item.Department.Name)
```

Run the app and select the **Courses** tab to see the list with department names.

Number	Title	Credits	Department	
1045	Calculus	4	Mathematics	Edit   Details   Delete
1050	Chemistry	3	Engineering	Edit   Details   Delete
2021	Composition	3	English	Edit   Details   Delete

### Loading related data with Select

The `OnGetAsync` method loads related data with the `Include` method:

```
public async Task OnGetAsync()
{
    Course = await _context.Courses
        .Include(c => c.Department)
        .AsNoTracking()
        .ToListAsync();
}
```

The `select` operator loads only the related data needed. For single items, like the `Department.Name` it uses a SQL INNER JOIN. For collections, it uses another database access, but so does the `Include` operator on collections.

The following code loads related data with the `Select` method:

```
public IList<CourseViewModel> CourseVM { get; set; }

public async Task OnGetAsync()
{
    CourseVM = await _context.Courses
        .Select(p => new CourseViewModel
        {
            CourseID = p.CourseID,
            Title = p.Title,
            Credits = p.Credits,
            DepartmentName = p.Department.Name
        }).ToListAsync();
}
```

The `CourseViewModel`:

```
public class CourseViewModel
{
    public int CourseID { get; set; }
    public string Title { get; set; }
    public int Credits { get; set; }
    public string DepartmentName { get; set; }
}
```

See [IndexSelect.cshtml](#) and [IndexSelect.cshtml.cs](#) for a complete example.

## Create an Instructors page that shows Courses and Enrollments

In this section, the Instructors page is created.

Instructors - Contoso University

localhost:1234/Instructors/3?courseID=1050&action=OnGetAsync

## Instructors

Create New

Last Name	First Name	Hire Date	Office	Courses

### Courses Taught by Selected Instructor

	Number	Title	Department
Select	1050	Chemistry	Engineering
Select	3141	Trigonometry	Mathematics

### Students Enrolled in Selected Course

Name	Grade
Alexander, Carson	A
Anand, Arturo	No grade
Barzdukas, Gytis	B

© 2017 - Contoso University

This page reads and displays related data in the following ways:

- The list of instructors displays related data from the `OfficeAssignment` entity (Office in the preceding image). The `Instructor` and `OfficeAssignment` entities are in a one-to-zero-or-one relationship. Eager loading is used for the `OfficeAssignment` entities. Eager loading is typically more efficient when the related data needs to be displayed. In this case, office assignments for the instructors are displayed.
- When the user selects an instructor (Harui in the preceding image), related `Course` entities are displayed. The

`Instructor` and `Course` entities are in a many-to-many relationship. Eager loading is used for the `Course` entities and their related `Department` entities. In this case, separate queries might be more efficient because only courses for the selected instructor are needed. This example shows how to use eager loading for navigation properties in entities that are in navigation properties.

- When the user selects a course (Chemistry in the preceding image), related data from the `Enrollments` entity is displayed. In the preceding image, student name and grade are displayed. The `Course` and `Enrollment` entities are in a one-to-many relationship.

### Create a view model for the Instructor Index view

The instructors page shows data from three different tables. A view model is created that includes the three entities representing the three tables.

In the `SchoolViewModels` folder, create `InstructorIndexData.cs` with the following code:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Threading.Tasks;

namespace ContosoUniversity.Models.SchoolViewModels
{
    public class InstructorIndexData
    {
        public IEnumerable<Instructor> Instructors { get; set; }
        public IEnumerable<Course> Courses { get; set; }
        public IEnumerable<Enrollment> Enrollments { get; set; }
    }
}
```

### Scaffold the Instructor model

- Exit Visual Studio.
- Open a command window in the project directory (The directory that contains the `Program.cs`, `Startup.cs`, and `.csproj` files).
- Run the following command:

```
dotnet aspnet-codegenerator razorpage -m Instructor -dc SchoolContext -udl -outDir Pages\Instructors --referenceScriptLibraries
```

The preceding command scaffolds the `Instructor` model. Open the project in Visual Studio.

Build the project. The build generates errors.

Globally change `_context.Instructor` to `_context.Instructors` (that is, add an "s" to `Instructor`). 7 occurrences are found and updated.

Run the app and navigate to the instructors page.

Replace `Pages\Instructors\Index.cshtml.cs` with the following code:

```

using ContosoUniversity.Models;
using ContosoUniversity.Models.SchoolViewModels; // Add VM
using Microsoft.AspNetCore.Mvc.RazorPages;
using Microsoft.EntityFrameworkCore;
using System.Linq;
using System.Threading.Tasks;

namespace ContosoUniversity.Pages.Instructors
{
    public class IndexModel : PageModel
    {
        private readonly ContosoUniversity.Data.SchoolContext _context;

        public IndexModel(ContosoUniversity.Data.SchoolContext context)
        {
            _context = context;
        }

        public InstructorIndexData Instructor { get; set; }
        public int InstructorID { get; set; }

        public async Task OnGetAsync(int? id)
        {
            Instructor = new InstructorIndexData();
            Instructor.Instructors = await _context.Instructors
                .Include(i => i.OfficeAssignment)
                .Include(i => i.CourseAssignments)
                .ThenInclude(i => i.Course)
                .AsNoTracking()
                .OrderBy(i => i.LastName)
                .ToListAsync();

            if (id != null)
            {
                InstructorID = id.Value;
            }
        }
    }
}

```

The `OnGetAsync` method accepts optional route data for the ID of the selected instructor.

Examine the query in the `Pages/Instructors/Index.cshtml.cs` file:

```

Instructor.Instructors = await _context.Instructors
    .Include(i => i.OfficeAssignment)
    .Include(i => i.CourseAssignments)
    .ThenInclude(i => i.Course)
    .AsNoTracking()
    .OrderBy(i => i.LastName)
    .ToListAsync();

```

The query has two includes:

- `OfficeAssignment` : Displayed in the [instructors view](#).
- `CourseAssignments` : Which brings in the courses taught.

## Update the instructors Index page

Update `Pages/Instructors/Index.cshtml` with the following markup:

```

@page "{id:int?}"
@model ContosoUniversity.Pages.Instructors.IndexModel

 @{
     ViewData["Title"] = "Instructors";
 }

<h2>Instructors</h2>

<p>
    <a asp-page="Create">Create New</a>
</p>
<table class="table">
    <thead>
        <tr>
            <th>Last Name</th>
            <th>First Name</th>
            <th>Hire Date</th>
            <th>Office</th>
            <th>Courses</th>
            <th></th>
        </tr>
    </thead>
    <tbody>
        @foreach (var item in Model.Instructor.Instructors)
        {
            string selectedRow = "";
            if (item.ID == Model.InstructorID)
            {
                selectedRow = "success";
            }
            <tr class="@selectedRow">
                <td>
                    @Html.DisplayFor(modelItem => item.LastName)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.FirstMidName)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.HireDate)
                </td>
                <td>
                    @if (item.OfficeAssignment != null)
                    {
                        @item.OfficeAssignment.Location
                    }
                </td>
                <td>
                    @{
                        foreach (var course in item.CourseAssignments)
                        {
                            @course.Course.CourseID @: @course.Course.Title <br />
                        }
                    }
                </td>
                <td>
                    <a asp-page=".~/Index" asp-route-id="@item.ID">Select</a> |
                    <a asp-page=".~/Edit" asp-route-id="@item.ID">Edit</a> |
                    <a asp-page=".~/Details" asp-route-id="@item.ID">Details</a> |
                    <a asp-page=".~/Delete" asp-route-id="@item.ID">Delete</a>
                </td>
            </tr>
        }
    </tbody>
</table>

```

The preceding markup makes the following changes:

- Updates the `page` directive from `@page` to `@page "{id:int?}"`. `{id:int?}"` is a route template. The route template changes integer query strings in the URL to route data. For example, clicking on the **Select** link for an instructor with only the `page` directive produces a URL like the following:

```
http://localhost:1234/Instructors?id=2
```

When the page directive is `@page "{id:int?}"`, the previous URL is:

```
http://localhost:1234/Instructors/2
```

- Page title is **Instructors**.
- Added an **Office** column that displays `item.OfficeAssignment.Location` only if `item.OfficeAssignment` isn't null. Because this is a one-to-zero-or-one relationship, there might not be a related `OfficeAssignment` entity.

```
@if (item.OfficeAssignment != null)
{
    @item.OfficeAssignment.Location
}
```

- Added a **Courses** column that displays courses taught by each instructor. See [Explicit Line Transition with @:](#) for more about this razor syntax.
- Added code that dynamically adds `class="success"` to the `tr` element of the selected instructor. This sets a background color for the selected row using a Bootstrap class.

```
string selectedRow = "";
if (item.CourseID == Model.CourseID)
{
    selectedRow = "success";
}
<tr class="@selectedRow">
```

- Added a new hyperlink labeled **Select**. This link sends the selected instructor's ID to the `Index` method and sets a background color.

```
<a asp-action="Index" asp-route-id="@item.ID">Select</a> |
```

Run the app and select the **Instructors** tab. The page displays the `Location` (office) from the related `OfficeAssignment` entity. If `OfficeAssignment`` is null, an empty table cell is displayed.

Last Name	First Name	Hire Date	Office	Courses
Abercrombie	Kim	1995-03-11		2021 Composition 2042 Literature
Fakhouri	Fadi	2002-07-06	Smith 17	1045 Calculus

Click on the **Select** link. The row style changes.

### Add courses taught by selected instructor

Update the `OnGetAsync` method in `Pages/Instructors/Index.cshtml.cs` with the following code:

```
public async Task OnGetAsync(int? id, int? courseID)
{
    Instructor = new InstructorIndexData();
    Instructor.Instructors = await _context.Instructors
        .Include(i => i.OfficeAssignment)
        .Include(i => i.CourseAssignments)
        .ThenInclude(i => i.Course)
        .ThenInclude(i => i.Department)
        .AsNoTracking()
        .OrderBy(i => i.LastName)
        .ToListAsync();

    if (id != null)
    {
        InstructorID = id.Value;
        Instructor instructor = Instructor.Instructors.Where(
            i => i.ID == id.Value).Single();
        Instructor.Courses = instructor.CourseAssignments.Select(s => s.Course);
    }

    if (courseID != null)
    {
        CourseID = courseID.Value;
        Instructor.Enrollments = Instructor.Courses.Where(
            x => x.CourseID == courseID).Single().Enrollments;
    }
}
```

Add `public int CourseID { get; set; }`

```

public class IndexModel : PageModel
{
    private readonly ContosoUniversity.Data.SchoolContext _context;

    public IndexModel(ContosoUniversity.Data.SchoolContext context)
    {
        _context = context;
    }

    public InstructorIndexData Instructor { get; set; }
    public int InstructorID { get; set; }
    public int CourseID { get; set; }

    public async Task OnGetAsync(int? id, int? courseID)
    {
        Instructor = new InstructorIndexData();
        Instructor.Instructors = await _context.Instructors
            .Include(i => i.OfficeAssignment)
            .Include(i => i.CourseAssignments)
            .ThenInclude(i => i.Course)
            .ThenInclude(i => i.Department)
            .AsNoTracking()
            .OrderBy(i => i.LastName)
            .ToListAsync();

        if (id != null)
        {
            InstructorID = id.Value;
            Instructor.instructor = Instructor.Instructors.Where(
                i => i.ID == id.Value).Single();
            Instructor.Courses = instructor.CourseAssignments.Select(s => s.Course);
        }

        if (courseID != null)
        {
            CourseID = courseID.Value;
            Instructor.Enrollments = Instructor.Courses.Where(
                x => x.CourseID == courseID).Single().Enrollments;
        }
    }
}

```

Examine the updated query:

```

Instructor.Instructors = await _context.Instructors
    .Include(i => i.OfficeAssignment)
    .Include(i => i.CourseAssignments)
    .ThenInclude(i => i.Course)
    .ThenInclude(i => i.Department)
    .AsNoTracking()
    .OrderBy(i => i.LastName)
    .ToListAsync();

```

The preceding query adds the `Department` entities.

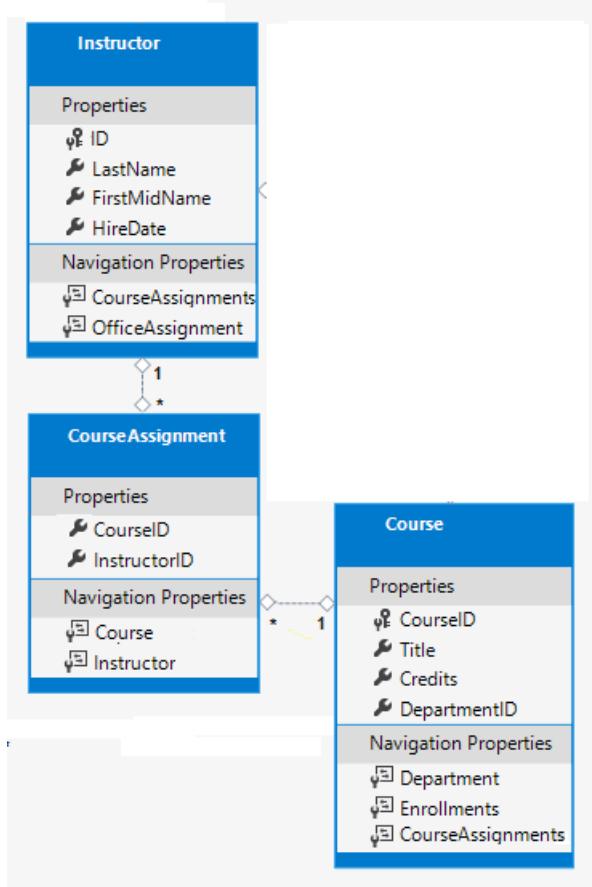

The following code executes when an instructor is selected (`id != null`). The selected instructor is retrieved from the list of instructors in the view model. The view model's `Courses` property is loaded with the `course` entities from that instructor's `CourseAssignments` navigation property.

```

if (id != null)
{
    InstructorID = id.Value;
    Instructor instructor = Instructor.Instructors.Where(
        i => i.ID == id.Value).Single();
    Instructor.Courses = instructor.CourseAssignments.Select(s => s.Course);
}

```

The `Where` method returns a collection. In the preceding `Where` method, only a single `Instructor` entity is returned. The `Single` method converts the collection into a single `Instructor` entity. The `Instructor` entity provides access to the `CourseAssignments` property. `CourseAssignments` provides access to the related `Course` entities.

The `Single` method is used on a collection when the collection has only one item. The `Single` method throws an exception if the collection is empty or if there's more than one item. An alternative is `SingleOrDefault`, which returns a default value (null in this case) if the collection is empty. Using `SingleOrDefault` on an empty collection:

- Results in an exception (from trying to find a `Courses` property on a null reference).
- The exception message would less clearly indicate the cause of the problem.

The following code populates the view model's `Enrollments` property when a course is selected:

```

if (courseID != null)
{
    CourseID = courseID.Value;
    Instructor.Enrollments = Instructor.Courses.Where(
        x => x.CourseID == courseID).Single().Enrollments;
}

```

Add the following markup to the end of the `Pages/Instructors/Index.cshtml` Razor Page:

```

        <a href="#" asp-page="./Delete" asp-route-id="@item.ID">Delete</a>
    </td>
</tr>
}
</tbody>
</table>

@if (Model.Instructor.Courses != null)
{
    <h3>Courses Taught by Selected Instructor</h3>
    <table class="table">
        <tr>
            <th></th>
            <th>Number</th>
            <th>Title</th>
            <th>Department</th>
        </tr>

        @foreach (var item in Model.Instructor.Courses)
        {
            string selectedRow = "";
            if (item.CourseID == Model.CourseID)
            {
                selectedRow = "success";
            }
            <tr class="@selectedRow">
                <td>
                    @Html.ActionLink("Select", "OnGetAsync",
                        new { courseID = item.CourseID })
                </td>
                <td>
                    @item.CourseID
                </td>
                <td>
                    @item.Title
                </td> <td>
                    @item.Department.Name
                </td>
            </tr>
        }
    </table>
}

```

The preceding markup displays a list of courses related to an instructor when an instructor is selected.

Test the app. Click on a **Select** link on the instructors page.

Last Name	First Name	Hire Date	Office	Courses
Abercrombie	Kim	1995-03-11		2021 Composition 2042 Literature
Fakhouri	Fadi	2002-07-06	Smith 17	1045 Calculus

## Courses Taught by Selected Instructor

	Number	Title	Department
Select	2021	Composition	English
Select	2042	Literature	English

## Show student data

In this section, the app is updated to show the student data for a selected course.

Update the query in the `onGetAsync` method in *Pages/Instructors/Index.cshtml.cs* with the following code:

```
Instructor.Instructors = await _context.Instructors
    .Include(i => i.OfficeAssignment)
    .Include(i => i.CourseAssignments)
    .ThenInclude(i => i.Course)
    .ThenInclude(i => i.Department)
    .Include(i => i.CourseAssignments)
    .ThenInclude(i => i.Course)
    .ThenInclude(i => i.Enrollments)
    .ThenInclude(i => i.Student)
    .AsNoTracking()
    .OrderBy(i => i.LastName)
    .ToListAsync();
```

Update *Pages/Instructors/Index.cshtml*. Add the following markup to the end of the file:

```
@if (Model.Instructor.Enrollments != null)
{
    <h3>
        Students Enrolled in Selected Course
    </h3>
    <table class="table">
        <tr>
            <th>Name</th>
            <th>Grade</th>
        </tr>
        @foreach (var item in Model.Instructor.Enrollments)
        {
            <tr>
                <td>
                    @item.Student.FullName
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Grade)
                </td>
            </tr>
        }
    </table>
}
```

The preceding markup displays a list of the students who are enrolled in the selected course.

Refresh the page and select an instructor. Select a course to see the list of enrolled students and their grades.

Instructors - Contoso Un X

localhost:1234/Instructors/3?courseID=1050&action=OnGetAsync

Contoso University

© 2017 - Contoso University

## Using Single

The `Single` method can pass in the `Where` condition instead of calling the `Where` method separately:

```

public async Task OnGetAsync(int? id, int? courseID)
{
    Instructor = new InstructorIndexData();

    Instructor.Instructors = await _context.Instructors
        .Include(i => i.OfficeAssignment)
        .Include(i => i.CourseAssignments)
        .ThenInclude(i => i.Course)
            .ThenInclude(i => i.Department)
        .Include(i => i.CourseAssignments)
            .ThenInclude(i => i.Course)
                .ThenInclude(i => i.Enrollments)
                    .ThenInclude(i => i.Student)
        .AsNoTracking()
        .OrderBy(i => i.LastName)
        .ToListAsync();

    if (id != null)
    {
        InstructorID = id.Value;
        Instructor instructor = Instructor.Instructors.Single(
            i => i.ID == id.Value);
        Instructor.Courses = instructor.CourseAssignments.Select(
            s => s.Course);
    }

    if (courseID != null)
    {
        CourseID = courseID.Value;
        Instructor.Enrollments = Instructor.Courses.Single(
            x => x.CourseID == courseID).Enrollments;
    }
}

```

The preceding `single` approach provides no benefits over using `where`. Some developers prefer the `single` approach style.

## Explicit loading

The current code specifies eager loading for `Enrollments` and `Students`:

```

Instructor.Instructors = await _context.Instructors
    .Include(i => i.OfficeAssignment)
    .Include(i => i.CourseAssignments)
    .ThenInclude(i => i.Course)
        .ThenInclude(i => i.Department)
    .Include(i => i.CourseAssignments)
        .ThenInclude(i => i.Course)
            .ThenInclude(i => i.Enrollments)
                .ThenInclude(i => i.Student)
    .AsNoTracking()
    .OrderBy(i => i.LastName)
    .ToListAsync();

```

Suppose users rarely want to see enrollments in a course. In that case, an optimization would be to only load the enrollment data if it's requested. In this section, the `OnGetAsync` is updated to use explicit loading of `Enrollments` and `Students`.

Update the `OnGetAsync` with the following code:

```

public async Task OnGetAsync(int? id, int? courseID)
{
    Instructor = new InstructorIndexData();
    Instructor.Instructors = await _context.Instructors
        .Include(i => i.OfficeAssignment)
        .Include(i => i.CourseAssignments)
        .ThenInclude(i => i.Course)
        .ThenInclude(i => i.Department)
        // .Include(i => i.CourseAssignments)
        //     .ThenInclude(i => i.Course)
        //         .ThenInclude(i => i.Enrollments)
        //             .ThenInclude(i => i.Student)
        // .AsNoTracking()
        .OrderBy(i => i.LastName)
        .ToListAsync();

    if (id != null)
    {
        InstructorID = id.Value;
        Instructor instructor = Instructor.Instructors.Where(
            i => i.ID == id.Value).Single();
        Instructor.Courses = instructor.CourseAssignments.Select(s => s.Course);
    }

    if (courseID != null)
    {
        CourseID = courseID.Value;
        var selectedCourse = Instructor.Courses.Where(x => x.CourseID == courseID).Single();
        await _context.Entry(selectedCourse).Collection(x => x.Enrollments).LoadAsync();
        foreach (Enrollment enrollment in selectedCourse.Enrollments)
        {
            await _context.Entry(enrollment).Reference(x => x.Student).LoadAsync();
        }
        Instructor.Enrollments = selectedCourse.Enrollments;
    }
}

```

The preceding code drops the `ThenInclude` method calls for enrollment and student data. If a course is selected, the highlighted code retrieves:

- The `Enrollment` entities for the selected course.
- The `Student` entities for each `Enrollment`.

Notice the preceding code comments out `.AsNoTracking()`. Navigation properties can only be explicitly loaded for tracked entities.

Test the app. From a users perspective, the app behaves identically to the previous version.

The next tutorial shows how to update related data.

# Razor Pages with EF Core in ASP.NET Core - Update Related Data - 7 of 8

6/21/2018 • 16 minutes to read • [Edit Online](#)

By [Tom Dykstra](#), and [Rick Anderson](#)

The Contoso University web app demonstrates how to create Razor Pages web apps using EF Core and Visual Studio. For information about the tutorial series, see [the first tutorial](#).

This tutorial demonstrates updating related data. If you run into problems you can't solve, download the [completed app for this stage](#).

The following illustrations shows some of the completed pages.

A screenshot of a web browser window displaying an 'Edit' page for a course. The browser's address bar shows 'localhost:58'. The page title is 'Contoso University'. The main content area has a heading 'Edit' and a sub-heading 'Course'. There are four form fields: 'Number' (value: 1000), 'Title' (value: Algebra 2), 'Credits' (value: 5), and 'Department' (dropdown menu showing 'Mathematics'). A 'Save' button is at the bottom left. The browser interface includes standard controls like back, forward, and search.

The screenshot shows a web browser window titled "Edit - Contoso University". The address bar displays "localhost:5813/Instruct". The main content area is titled "Edit" and has a sub-section "Instructor". It contains the following form fields:

- Last Name:** Abercrombie
- First Name:** Kim
- Hire Date:** 3/11/1995
- Office Location:** 44/3P

Below these fields is a list of course checkboxes:

<input type="checkbox"/> 1000 Algebra 2	<input type="checkbox"/> 1045 Calculus	<input type="checkbox"/> 1050 Chemistry
<input checked="" type="checkbox"/> 2021 Composition	<input checked="" type="checkbox"/> 2042 Literature	<input type="checkbox"/> 3141 Trigonometry
<input type="checkbox"/> 4022 Microeconomics	<input type="checkbox"/> 4041 Macroeconomics	

A "Save" button is located at the bottom left of the form.

Examine and test the Create and Edit course pages. Create a new course. The department is selected by its primary key (an integer), not its name. Edit the new course. When you have finished testing, delete the new course.

## Create a base class to share common code

The Courses/Create and Courses/Edit pages each need a list of department names. Create the *Pages/Courses/DepartmentNamePageModel.cshtml.cs* base class for the Create and Edit pages:

```

using ContosoUniversity.Data;
using Microsoft.AspNetCore.Mvc.RazorPages;
using Microsoft.AspNetCore.Mvc.Rendering;
using Microsoft.EntityFrameworkCore;
using System.Linq;

namespace ContosoUniversity.Pages.Courses
{
    public class DepartmentNamePageModel : PageModel
    {
        public SelectList DepartmentNameSL { get; set; }

        public void PopulateDepartmentsDropDownList(SchoolContext _context,
            object selectedDepartment = null)
        {
            var departmentsQuery = from d in _context.Departments
                orderby d.Name // Sort by name.
                select d;

            DepartmentNameSL = new SelectList(departmentsQuery.AsNoTracking(),
                "DepartmentID", "Name", selectedDepartment);
        }
    }
}

```

The preceding code creates a `SelectList` to contain the list of department names. If `selectedDepartment` is specified, that department is selected in the `SelectList`.

The Create and Edit page model classes will derive from `DepartmentNamePageModel`.

## Customize the Courses Pages

When a new course entity is created, it must have a relationship to an existing department. To add a department while creating a course, the base class for Create and Edit contains a drop-down list for selecting the department. The drop-down list sets the `Course.DepartmentID` foreign key (FK) property. EF Core uses the `Course.DepartmentID` FK to load the `Department` navigation property.

Screenshot of a web browser showing the 'Create' page for a 'Course'. The URL is 'localhost:1234/Courses/Create'. The page title is 'Create DepartmentName'. The page header says 'Contoso University'. The main content area has a heading 'Create' and a sub-heading 'Course'. There are four input fields: 'Number' (value: 1003), 'Title' (value: Algebra 2), 'Credits' (value: 3), and a 'Department' dropdown menu. The 'Department' dropdown is highlighted with a red border. It contains the following options: '-- Select Department --', 'Economics', 'Engineering', 'English', and 'Mathematics'. The option '-- Select Department --' is currently selected.

Number  
1003

Title  
Algebra 2

Credits  
3

Department

-- Select Department --

-- Select Department --

Economics

Engineering

English

Mathematics

Update the Create page model with the following code:

```

using ContosoUniversity.Models;
using Microsoft.AspNetCore.Mvc;
using System.Threading.Tasks;

namespace ContosoUniversity.Pages.Courses
{
    public class CreateModel : DepartmentNamePageModel
    {
        private readonly ContosoUniversity.Data.SchoolContext _context;

        public CreateModel(ContosoUniversity.Data.SchoolContext context)
        {
            _context = context;
        }

        public IActionResult OnGet()
        {
            PopulateDepartmentsDropDownList(_context);
            return Page();
        }

        [BindProperty]
        public Course Course { get; set; }

        public async Task<IActionResult> OnPostAsync()
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }

            var emptyCourse = new Course();

            if (await TryUpdateModelAsync<Course>(
                emptyCourse,
                "course", // Prefix for form value.
                s => s.CourseID, s => s.DepartmentID, s => s.Title, s => s.Credits))
            {
                _context.Courses.Add(emptyCourse);
                await _context.SaveChangesAsync();
                return RedirectToPage("./Index");
            }

            // Select DepartmentID if TryUpdateModelAsync fails.
            PopulateDepartmentsDropDownList(_context, emptyCourse.DepartmentID);
            return Page();
        }
    }
}

```

The preceding code:

- Derives from `DepartmentNamePageModel`.
- Uses `TryUpdateModelAsync` to prevent [overposting](#).
- Replaces `ViewData["DepartmentID"]` with `DepartmentNameSL` (from the base class).

`ViewData["DepartmentID"]` is replaced with the strongly typed `DepartmentNameSL`. Strongly typed models are preferred over weakly typed. For more information, see [Weakly typed data \(ViewData and ViewBag\)](#).

## Update the Courses Create page

Update `Pages/Courses/Create.cshtml` with the following markup:

```

@page
@model ContosoUniversity.Pages.Courses.CreateModel
 @{
     ViewData["Title"] = "Create Course";
 }
<h2>Create</h2>
<h4>Course</h4>
<hr />
<div class="row">
    <div class="col-md-4">
        <form method="post">
            <div asp-validation-summary="ModelOnly" class="text-danger"></div>
            <div class="form-group">
                <label asp-for="Course.CourseID" class="control-label"></label>
                <input asp-for="Course.CourseID" class="form-control" />
                <span asp-validation-for="Course.CourseID" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Course.Title" class="control-label"></label>
                <input asp-for="Course.Title" class="form-control" />
                <span asp-validation-for="Course.Title" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Course.Credits" class="control-label"></label>
                <input asp-for="Course.Credits" class="form-control" />
                <span asp-validation-for="Course.Credits" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Course.Department" class="control-label"></label>
                <select asp-for="Course.DepartmentID" class="form-control" asp-items="@Model.DepartmentNameSL">
                    <option value="">-- Select Department --</option>
                </select>
                <span asp-validation-for="Course.DepartmentID" class="text-danger" />
            </div>
            <div class="form-group">
                <input type="submit" value="Create" class="btn btn-default" />
            </div>
        </form>
    </div>
</div>
<a asp-page="Index">Back to List</a>
</div>
@section Scripts {
    @{await Html.RenderPartialAsync("_ValidationScriptsPartial");}
}

```

The preceding markup makes the following changes:

- Changes the caption from **DepartmentID** to **Department**.
- Replaces `"ViewBag.DepartmentID"` with `DepartmentNamesL` (from the base class).
- Adds the "Select Department" option. This change renders "Select Department" rather than the first department.
- Adds a validation message when the department isn't selected.

The Razor Page uses the [Select Tag Helper](#):

```
<div class="form-group">
    <label asp-for="Course.Department" class="control-label"></label>
    <select asp-for="Course.DepartmentID" class="form-control"
        asp-items="@Model.DepartmentNameSL">
        <option value="">-- Select Department --</option>
    </select>
    <span asp-validation-for="Course.DepartmentID" class="text-danger" />
</div>
```

Test the Create page. The Create page displays the department name rather than the department ID.

### **Update the Courses Edit page.**

Update the edit page model with the following code:

```

using ContosoUniversity.Models;
using Microsoft.AspNetCore.Mvc;
using Microsoft.EntityFrameworkCore;
using System.Threading.Tasks;

namespace ContosoUniversity.Pages.Courses
{
    public class EditModel : DepartmentNamePageModel
    {
        private readonly ContosoUniversity.Data.SchoolContext _context;

        public EditModel(ContosoUniversity.Data.SchoolContext context)
        {
            _context = context;
        }

        [BindProperty]
        public Course Course { get; set; }

        public async Task<IActionResult> OnGetAsync(int? id)
        {
            if (id == null)
            {
                return NotFound();
            }

            Course = await _context.Courses
                .Include(c => c.Department).FirstOrDefaultAsync(m => m.CourseID == id);

            if (Course == null)
            {
                return NotFound();
            }

            // Select current DepartmentID.
            PopulateDepartmentsDropDownList(_context, Course.DepartmentID);
            return Page();
        }

        public async Task<IActionResult> OnPostAsync(int? id)
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }

            var courseToUpdate = await _context.Courses.FindAsync(id);

            if (await TryUpdateModelAsync<Course>(
                courseToUpdate,
                "course", // Prefix for form value.
                c => c.Credits, c => c.DepartmentID, c => c.Title))
            {
                await _context.SaveChangesAsync();
                return RedirectToPage("./Index");
            }

            // Select DepartmentID if TryUpdateModelAsync fails.
            PopulateDepartmentsDropDownList(_context, courseToUpdate.DepartmentID);
            return Page();
        }
    }
}

```

The changes are similar to those made in the Create page model. In the preceding code,

`PopulateDepartmentsDropDownList` passes in the department ID, which select the department specified in the drop-

down list.

Update *Pages/Courses/Edit.cshtml* with the following markup:

```
@page
@model ContosoUniversity.Pages.Courses.EditModel

@{
    ViewData["Title"] = "Edit";
}

<h2>Edit</h2>

<h4>Course</h4>
<hr />

<div class="col-md-4">
        <form method="post">
            <div asp-validation-summary="ModelOnly" class="text-danger"></div>
            <input type="hidden" asp-for="Course.CourseID" />
            <div class="form-group">
                <label asp-for="Course.CourseID" class="control-label"></label>
                <div>@Html.DisplayFor(model => model.Course.CourseID)</div>
            </div>
            <div class="form-group">
                <label asp-for="Course.Title" class="control-label"></label>
                <input asp-for="Course.Title" class="form-control" />
                <span asp-validation-for="Course.Title" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Course.Credits" class="control-label"></label>
                <input asp-for="Course.Credits" class="form-control" />
                <span asp-validation-for="Course.Credits" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Course.Department" class="control-label"></label>
                <select asp-for="Course.DepartmentID" class="form-control" asp-items="@Model.DepartmentNameSL"></select>
                <span asp-validation-for="Course.DepartmentID" class="text-danger"></span>
            </div>
            <div class="form-group">
                <input type="submit" value="Save" class="btn btn-default" />
            </div>
        </form>
    </div>

The preceding markup makes the following changes:

- Displays the course ID. Generally the Primary Key (PK) of an entity isn't displayed. PKs are usually meaningless to users. In this case, the PK is the course number.
- Changes the caption from DepartmentID to Department.
- Replaces "ViewBag.DepartmentID" with DepartmentNameSL (from the base class).

The page contains a hidden field (<input type="hidden">) for the course number. Adding a <label> tag helper with asp-for="Course.CourseID" doesn't eliminate the need for the hidden field. <input type="hidden"> is required

```

for the course number to be included in the posted data when the user clicks **Save**.

Test the updated code. Create, edit, and delete a course.

## Add `AsNoTracking` to the Details and Delete page models

`AsNoTracking` can improve performance when tracking isn't required. Add `AsNoTracking` to the Delete and Details page model. The following code shows the updated Delete page model:

```
public class DeleteModel : PageModel
{
    private readonly ContosoUniversity.Data.SchoolContext _context;

    public DeleteModel(ContosoUniversity.Data.SchoolContext context)
    {
        _context = context;
    }

    [BindProperty]
    public Course Course { get; set; }

    public async Task<IActionResult> OnGetAsync(int? id)
    {
        if (id == null)
        {
            return NotFound();
        }

        Course = await _context.Courses
            .AsNoTracking()
            .Include(c => c.Department)
            .FirstOrDefaultAsync(m => m.CourseID == id);

        if (Course == null)
        {
            return NotFound();
        }
        return Page();
    }

    public async Task<IActionResult> OnPostAsync(int? id)
    {
        if (id == null)
        {
            return NotFound();
        }

        Course = await _context.Courses
            .AsNoTracking()
            .FirstOrDefaultAsync(m => m.CourseID == id);

        if (Course != null)
        {
            _context.Courses.Remove(Course);
            await _context.SaveChangesAsync();
        }

        return RedirectToPage("./Index");
    }
}
```

Update the `OnGetAsync` method in the *Pages/Courses/Details.cshtml.cs* file:

```
public async Task<IActionResult> OnGetAsync(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    Course = await _context.Courses
        .AsNoTracking()
        .Include(c => c.Department)
        .FirstOrDefaultAsync(m => m.CourseID == id);

    if (Course == null)
    {
        return NotFound();
    }
    return Page();
}
```

## Modify the Delete and Details pages

Update the Delete Razor page with the following markup:

```

@page
@model ContosoUniversity.Pages.Courses.DeleteModel

 @{
     ViewData["Title"] = "Delete";
 }

<h2>Delete</h2>

<h3>Are you sure you want to delete this?</h3>
<div>
    <h4>Course</h4>
    <hr />
    <dl class="dl-horizontal">
        <dt>
            @Html.DisplayNameFor(model => model.Course.CourseID)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Course.CourseID)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Course.Title)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Course.Title)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Course.Credits)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Course.Credits)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Course.Department)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Course.Department.DepartmentID)
        </dd>
    </dl>

    <form method="post">
        <input type="hidden" asp-for="Course.CourseID" />
        <input type="submit" value="Delete" class="btn btn-default" /> |
        <a asp-page="./Index">Back to List</a>
    </form>
</div>

```

Make the same changes to the Details page.

## Test the Course pages

Test create, edit, details, and delete.

## Update the instructor pages

The following sections update the instructor pages.

### Add office location

When editing an instructor record, you may want to update the instructor's office assignment. The `Instructor` entity has a one-to-zero-or-one relationship with the `OfficeAssignment` entity. The instructor code must handle:

- If the user clears the office assignment, delete the `OfficeAssignment` entity.
- If the user enters an office assignment and it was empty, create a new `OfficeAssignment` entity.

- If the user changes the office assignment, update the `OfficeAssignment` entity.

Update the instructors Edit page model with the following code:

```
public class EditModel : PageModel
{
    private readonly ContosoUniversity.Data.SchoolContext _context;

    public EditModel(ContosoUniversity.Data.SchoolContext context)
    {
        _context = context;
    }

    [BindProperty]
    public Instructor Instructor { get; set; }

    public async Task<IActionResult> OnGetAsync(int? id)
    {
        if (id == null)
        {
            return NotFound();
        }

        Instructor = await _context.Instructors
            .Include(i => i.OfficeAssignment)
            .AsNoTracking()
            .FirstOrDefaultAsync(m => m.ID == id);

        if (Instructor == null)
        {
            return NotFound();
        }
        return Page();
    }

    public async Task<IActionResult> OnPostAsync(int? id)
    {
        if (!ModelState.IsValid)
        {
            return Page();
        }

        var instructorToUpdate = await _context.Instructors
            .Include(i => i.OfficeAssignment)
            .FirstOrDefaultAsync(s => s.ID == id);

        if (await TryUpdateModelAsync<Instructor>(
            instructorToUpdate,
            "Instructor",
            i => i.FirstMidName, i => i.LastName,
            i => i.HireDate, i => i.OfficeAssignment))
        {
            if (String.IsNullOrWhiteSpace(
                instructorToUpdate.OfficeAssignment?.Location))
            {
                instructorToUpdate.OfficeAssignment = null;
            }
            await _context.SaveChangesAsync();
        }
        return RedirectToPage("./Index");
    }
}
```

The preceding code:

- Gets the current `Instructor` entity from the database using eager loading for the `OfficeAssignment` navigation property.
- Updates the retrieved `Instructor` entity with values from the model binder. `TryUpdateModel` prevents **overposting**.
- If the office location is blank, sets `Instructor.OfficeAssignment` to null. When `Instructor.OfficeAssignment` is null, the related row in the `OfficeAssignment` table is deleted.

## Update the instructor Edit page

Update `Pages/Instructors/Edit.cshtml` with the office location:

```

@page
@model ContosoUniversity.Pages.Instructors.EditModel
 @{
    ViewData["Title"] = "Edit";
}
<h2>Edit</h2>
<h4>Instructor</h4>
<hr />
<div class="row">
    <div class="col-md-4">
        <form method="post">
            <div asp-validation-summary="ModelOnly" class="text-danger"></div>
            <input type="hidden" asp-for="Instructor.ID" />
            <div class="form-group">
                <label asp-for="Instructor.LastName" class="control-label"></label>
                <input asp-for="Instructor.LastName" class="form-control" />
                <span asp-validation-for="Instructor.LastName" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Instructor.FirstMidName" class="control-label"></label>
                <input asp-for="Instructor.FirstMidName" class="form-control" />
                <span asp-validation-for="Instructor.FirstMidName" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Instructor.HireDate" class="control-label"></label>
                <input asp-for="Instructor.HireDate" class="form-control" />
                <span asp-validation-for="Instructor.HireDate" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Instructor.OfficeAssignment.Location" class="control-label"></label>
                <input asp-for="Instructor.OfficeAssignment.Location" class="form-control" />
                <span asp-validation-for="Instructor.OfficeAssignment.Location" class="text-danger" />
            </div>
            <div class="form-group">
                <input type="submit" value="Save" class="btn btn-default" />
            </div>
        </form>
    </div>
</div>
<div>
    <a asp-page=".~/Index">Back to List</a>
</div>

@section Scripts {
    @{await Html.RenderPartialAsync("_ValidationScriptsPartial");}
}

```

Verify you can change an instructors office location.

## Add Course assignments to the instructor Edit page

Instructors may teach any number of courses. In this section, you add the ability to change course assignments.

The following image shows the updated instructor Edit page:

Last Name  
Abercrombie

First Name  
Kim

Hire Date  
3/11/1995

Office Location  
44/3P

1000 Algebra 2    1045 Calculus    1050 Chemistry  
 2021 Composition    2042 Literature    3141 Trigonometry  
 4022 Microeconomics    4041 Macroeconomics

Save

`Course` and `Instructor` has a many-to-many relationship. To add and remove relationships, you add and remove entities from the `CourseAssignments` join entity set.

Check boxes enable changes to courses an instructor is assigned to. A check box is displayed for every course in the database. Courses that the instructor is assigned to are checked. The user can select or clear check boxes to change course assignments. If the number of courses were much greater:

- You'd probably use a different user interface to display the courses.
- The method of manipulating a join entity to create or delete relationships wouldn't change.

#### Add classes to support Create and Edit instructor pages

Create `SchoolViewModels/AssignedCourseData.cs` with the following code:

```
namespace ContosoUniversity.Models.SchoolViewModels
{
    public class AssignedCourseData
    {
        public int CourseID { get; set; }
        public string Title { get; set; }
        public bool Assigned { get; set; }
    }
}
```

The `AssignedCourseData` class contains data to create the check boxes for assigned courses by an instructor.

Create the *Pages/Instructors/InstructorCoursesPageModel.cshtml.cs* base class:

```
using ContosoUniversity.Data;
using ContosoUniversity.Models;
using ContosoUniversity.Models.SchoolViewModels;
using Microsoft.AspNetCore.Mvc.RazorPages;
using System.Collections.Generic;
using System.Linq;

namespace ContosoUniversity.Pages.Instructors
{
    public class InstructorCoursesPageModel : PageModel
    {

        public List<AssignedCourseData> AssignedCourseDataList;

        public void PopulateAssignedCourseData(SchoolContext context,
                                              Instructor instructor)
        {
            var allCourses = context.Courses;
            var instructorCourses = new HashSet<int>(
                instructor.CourseAssignments.Select(c => c.CourseID));
            AssignedCourseDataList = new List<AssignedCourseData>();
            foreach (var course in allCourses)
            {
                AssignedCourseDataList.Add(new AssignedCourseData
                {
                    CourseID = course.CourseID,
                    Title = course.Title,
                    Assigned = instructorCourses.Contains(course.CourseID)
                });
            }
        }

        public void UpdateInstructorCourses(SchoolContext context,
                                            string[] selectedCourses, Instructor instructorToUpdate)
        {
            if (selectedCourses == null)
            {
                instructorToUpdate.CourseAssignments = new List<CourseAssignment>();
                return;
            }

            var selectedCoursesHS = new HashSet<string>(selectedCourses);
            var instructorCourses = new HashSet<int>(
                (instructorToUpdate.CourseAssignments.Select(c => c.Course.CourseID)));
            foreach (var course in context.Courses)
            {
                if (selectedCoursesHS.Contains(course.CourseID.ToString()))
                {
                    if (!instructorCourses.Contains(course.CourseID))
                    {
                        instructorToUpdate.CourseAssignments.Add(
                            new CourseAssignment
                            {
                                InstructorID = instructorToUpdate.ID,
                                CourseID = course.CourseID
                            });
                    }
                }
                else
                {
                    if (instructorCourses.Contains(course.CourseID))
                    {
                        CourseAssignment courseToRemove
                            = instructorToUpdate
                                .CourseAssignments
                                .SingleOrDefault(i => i.CourseID == course.CourseID);
                    }
                }
            }
        }
    }
}
```

```
        context.Remove(courseToRemove);
    }
}
}
}
}
```

The `InstructorCoursesPageModel` is the base class you will use for the Edit and Create page models.

`PopulateAssignedCourseData` reads all `Course` entities to populate `AssignedCourseDataList`. For each course, the code sets the `CourseID`, title, and whether or not the instructor is assigned to the course. A `HashSet` is used to create efficient lookups.

### Instructors Edit page model

Update the instructor Edit page model with the following code:

```

public class EditModel : InstructorCoursesPageModel
{
    private readonly ContosoUniversity.Data.SchoolContext _context;

    public EditModel(ContosoUniversity.Data.SchoolContext context)
    {
        _context = context;
    }

    [BindProperty]
    public Instructor Instructor { get; set; }

    public async Task<IActionResult> OnGetAsync(int? id)
    {
        if (id == null)
        {
            return NotFound();
        }

        Instructor = await _context.Instructors
            .Include(i => i.OfficeAssignment)
            .Include(i => i.CourseAssignments).ThenInclude(i => i.Course)
            .AsNoTracking()
            .FirstOrDefaultAsync(m => m.ID == id);

        if (Instructor == null)
        {
            return NotFound();
        }
        PopulateAssignedCourseData(_context, Instructor);
        return Page();
    }

    public async Task<IActionResult> OnPostAsync(int? id, string[] selectedCourses)
    {
        if (!ModelState.IsValid)
        {
            return Page();
        }

        var instructorToUpdate = await _context.Instructors
            .Include(i => i.OfficeAssignment)
            .Include(i => i.CourseAssignments)
            .ThenInclude(i => i.Course)
            .FirstOrDefaultAsync(s => s.ID == id);

        if (await TryUpdateModelAsync<Instructor>(
            instructorToUpdate,
            "Instructor",
            i => i.FirstMidName, i => i.LastName,
            i => i.HireDate, i => i.OfficeAssignment))
        {
            if (String.IsNullOrWhiteSpace(
                instructorToUpdate.OfficeAssignment?.Location))
            {
                instructorToUpdate.OfficeAssignment = null;
            }
            UpdateInstructorCourses(_context, selectedCourses, instructorToUpdate);
            await _context.SaveChangesAsync();
            return RedirectToPage("./Index");
        }
        UpdateInstructorCourses(_context, selectedCourses, instructorToUpdate);
        PopulateAssignedCourseData(_context, instructorToUpdate);
        return Page();
    }
}

```

The preceding code handles office assignment changes.

Update the instructor Razor View:

```
@page
@model ContosoUniversity.Pages.Instructors.EditModel
 @{
    ViewData["Title"] = "Edit";
}
<h2>Edit</h2>
<h4>Instructor</h4>
<hr />

<div class="col-md-4">
        <form method="post">
            <div asp-validation-summary="ModelOnly" class="text-danger"></div>
            <input type="hidden" asp-for="Instructor.ID" />
            <div class="form-group">
                <label asp-for="Instructor.LastName" class="control-label"></label>
                <input asp-for="Instructor.LastName" class="form-control" />
                <span asp-validation-for="Instructor.LastName" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Instructor.FirstMidName" class="control-label"></label>
                <input asp-for="Instructor.FirstMidName" class="form-control" />
                <span asp-validation-for="Instructor.FirstMidName" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Instructor.HireDate" class="control-label"></label>
                <input asp-for="Instructor.HireDate" class="form-control" />
                <span asp-validation-for="Instructor.HireDate" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Instructor.OfficeAssignment.Location" class="control-label"></label>
                <input asp-for="Instructor.OfficeAssignment.Location" class="form-control" />
                <span asp-validation-for="Instructor.OfficeAssignment.Location" class="text-danger" />
            </div>
            <div class="form-group">
                <div class="col-md-offset-2 col-md-10">
                    <table>
                        <tr>
                            @{
                                int cnt = 0;

                                foreach (var course in Model.AssignedCourseDataList)
                                {
                                    if (cnt++ % 3 == 0)
                                    {
                                        @:</tr><tr>
                                    }
                                    @:<td>
                                        <input type="checkbox"
                                                name="selectedCourses"
                                                value="@course.CourseID"
                                                @(Html.Raw(course.Assigned ? "checked=\"checked\"" : ""))
                                                @course.CourseID @: @course.Title
                                    @:</td>
                                }
                                @:</tr>
                            }
                        </table>
                </div>
            <div class="form-group">
                <input type="submit" value="Save" class="btn btn-default" />
            </div>
        </form>
    </div>

```

```

</div>

<div>
    <a asp-page=".~/Index">Back to List</a>
</div>

@section Scripts {
    @{await Html.RenderPartialAsync("_ValidationScriptsPartial");}
}

```

#### **NOTE**

When you paste the code in Visual Studio, line breaks are changed in a way that breaks the code. Press Ctrl+Z one time to undo the automatic formatting. Ctrl+Z fixes the line breaks so that they look like what you see here. The indentation doesn't have to be perfect, but the `@</tr><tr>`, `@:<td>`, `@:</td>`, and `@:</tr>` lines must each be on a single line as shown. With the block of new code selected, press Tab three times to line up the new code with the existing code. Vote on or review the status of this bug [with this link](#).

The preceding code creates an HTML table that has three columns. Each column has a check box and a caption containing the course number and title. The check boxes all have the same name ("selectedCourses"). Using the same name informs the model binder to treat them as a group. The value attribute of each check box is set to `CourseID`. When the page is posted, the model binder passes an array that consists of the `CourseID` values for only the check boxes that are selected.

When the check boxes are initially rendered, courses assigned to the instructor have checked attributes.

Run the app and test the updated instructors Edit page. Change some course assignments. The changes are reflected on the Index page.

Note: The approach taken here to edit instructor course data works well when there's a limited number of courses. For collections that are much larger, a different UI and a different updating method would be more useable and efficient.

#### **Update the instructors Create page**

Update the instructor Create page model with the following code:

```

using ContosoUniversity.Models;
using Microsoft.AspNetCore.Mvc;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace ContosoUniversity.Pages.Instructors
{
    public class CreateModel : InstructorCoursesPageModel
    {
        private readonly ContosoUniversity.Data.SchoolContext _context;

        public CreateModel(ContosoUniversity.Data.SchoolContext context)
        {
            _context = context;
        }

        public IActionResult OnGet()
        {
            var instructor = new Instructor();
            instructor.CourseAssignments = new List<CourseAssignment>();

            // Provides an empty collection for the foreach loop
            // foreach (var course in Model.AssignedCourseDataList)
            // in the Create Razor page.
            PopulateAssignedCourseData( context, instructor);
        }
    }
}

```

```

        return Page();
    }

    [BindProperty]
    public Instructor Instructor { get; set; }

    public async Task<IActionResult> OnPostAsync(string[] selectedCourses)
    {
        if (!ModelState.IsValid)
        {
            return Page();
        }

        var newInstructor = new Instructor();
        if (selectedCourses != null)
        {
            newInstructor.CourseAssignments = new List<CourseAssignment>();
            foreach (var course in selectedCourses)
            {
                var courseToAdd = new CourseAssignment
                {
                    CourseID = int.Parse(course)
                };
                newInstructor.CourseAssignments.Add(courseToAdd);
            }
        }

        if (await TryUpdateModelAsync<Instructor>(
            newInstructor,
            "Instructor",
            i => i.FirstMidName, i => i.LastName,
            i => i.HireDate, i => i.OfficeAssignment))
        {
            _context.Instructors.Add(newInstructor);
            await _context.SaveChangesAsync();
            return RedirectToPage("./Index");
        }
        PopulateAssignedCourseData(_context, newInstructor);
        return Page();
    }
}
}
}

```

The preceding code is similar to the *Pages/Instructors/Edit.cshtml.cs* code.

Update the instructor Create Razor page with the following markup:

```

@page
@model ContosoUniversity.Pages.Instructors.CreateModel

 @{
     ViewData["Title"] = "Create";
 }

<h2>Create</h2>

<h4>Instructor</h4>
<hr />
<div class="row">
    <div class="col-md-4">
        <form method="post">
            <div asp-validation-summary="ModelOnly" class="text-danger"></div>
            <div class="form-group">
                <label asp-for="Instructor.LastName" class="control-label"></label>
                <input asp-for="Instructor.LastName" class="form-control" />
                <span asp-validation-for="Instructor.LastName" class="text-danger"></span>
            </div>
    </div>

```

```

<div class="form-group">
    <label asp-for="Instructor.FirstMidName" class="control-label"></label>
    <input asp-for="Instructor.FirstMidName" class="form-control" />
    <span asp-validation-for="Instructor.FirstMidName" class="text-danger"></span>
</div>
<div class="form-group">
    <label asp-for="Instructor.HireDate" class="control-label"></label>
    <input asp-for="Instructor.HireDate" class="form-control" />
    <span asp-validation-for="Instructor.HireDate" class="text-danger"></span>
</div>

<div class="form-group">
    <label asp-for="Instructor.OfficeAssignment.Location" class="control-label"></label>
    <input asp-for="Instructor.OfficeAssignment.Location" class="form-control" />
    <span asp-validation-for="Instructor.OfficeAssignment.Location" class="text-danger" />
</div>
<div class="form-group">
    <div class="col-md-offset-2 col-md-10">
        <table>
            <tr>
                @{
                    int cnt = 0;

                    foreach (var course in Model.AssignedCourseDataList)
                    {
                        if (cnt++ % 3 == 0)
                        {
                            @:</tr><tr>
                        }
                        @:<td>
                            <input type="checkbox"
                                name="selectedCourses"
                                value="@course.CourseID"
                                @(Html.Raw(course.Assigned ? "checked=\"checked\"" : ""))
                                @course.CourseID @: @course.Title
                            @:</td>
                        }
                        @:</tr>
                    }
                </table>
            </div>
        <div class="form-group">
            <input type="submit" value="Create" class="btn btn-default" />
        </div>
    </form>
</div>
</div>

<div>
    <a asp-page="Index">Back to List</a>
</div>

@section Scripts {
    @{await Html.RenderPartialAsync("_ValidationScriptsPartial");}
}

```

Test the instructor Create page.

## Update the Delete page

Update the Delete page model with the following code:

```

using ContosoUniversity.Models;
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using Microsoft.EntityFrameworkCore;
using System.Linq;
using System.Threading.Tasks;

namespace ContosoUniversity.Pages.Instructors
{
    public class DeleteModel : PageModel
    {
        private readonly ContosoUniversity.Data.SchoolContext _context;

        public DeleteModel(ContosoUniversity.Data.SchoolContext context)
        {
            _context = context;
        }

        [BindProperty]
        public Instructor Instructor { get; set; }

        public async Task<IActionResult> OnGetAsync(int? id)
        {
            if (id == null)
            {
                return NotFound();
            }

            Instructor = await _context.Instructors.SingleAsync(m => m.ID == id);

            if (Instructor == null)
            {
                return NotFound();
            }
            return Page();
        }

        public async Task<IActionResult> OnPostAsync(int id)
        {
            Instructor instructor = await _context.Instructors
                .Include(i => i.CourseAssignments)
                .SingleAsync(i => i.ID == id);

            var departments = await _context.Departments
                .Where(d => d.InstructorID == id)
                .ToListAsync();
            departments.ForEach(d => d.InstructorID = null);

            _context.Instructors.Remove(instructor);

            await _context.SaveChangesAsync();
            return RedirectToPage("./Index");
        }
    }
}

```

The preceding code makes the following changes:

- Uses eager loading for the `CourseAssignments` navigation property. `CourseAssignments` must be included or they aren't deleted when the instructor is deleted. To avoid needing to read them, configure cascade delete in the database.
- If the instructor to be deleted is assigned as administrator of any departments, removes the instructor assignment from those departments.

# Razor Pages with EF Core in ASP.NET Core - Concurrency - 8 of 8

By [Rick Anderson](#), [Tom Dykstra](#), and [Jon P Smith](#)

The Contoso University web app demonstrates how to create Razor Pages web apps using EF Core and Visual Studio. For information about the tutorial series, see [the first tutorial](#).

This tutorial shows how to handle conflicts when multiple users update an entity concurrently (at the same time). If you run into problems you can't solve, download the [completed app for this stage](#).

## Concurrency conflicts

A concurrency conflict occurs when:

- A user navigates to the edit page for an entity.
- Another user updates the same entity before the first user's change is written to the DB.

If concurrency detection isn't enabled, when concurrent updates occur:

- The last update wins. That is, the last update values are saved to the DB.
- The first of the current updates are lost.

### Optimistic concurrency

Optimistic concurrency allows concurrency conflicts to happen, and then reacts appropriately when they do. For example, Jane visits the Department edit page and changes the budget for the English department from \$350,000.00 to \$0.00.

Edit

Department

Budget

Administrator

Name

Start Date

Save

Before Jane clicks **Save**, John visits the same page and changes the Start Date field from 9/1/2007 to 9/1/2013.

Edit

Department

Budget

Administrator

Name

Start Date

Save

Jane clicks **Save** first and sees her change when the browser displays the Index page.

Name	Budget	Administrator	Start Date	
English	\$0.00	Abercrombie, Kim	2007-09-01	Edit   Details   Delete
Mather	\$350,000.00	Eakhouri, Fadi	2007-09-01	Edit   Details   Delete

John clicks **Save** on an Edit page that still shows a budget of \$350,000.00. What happens next is determined by how you handle concurrency conflicts.

Optimistic concurrency includes the following options:

- You can keep track of which property a user has modified and update only the corresponding columns in the DB.

In the scenario, no data would be lost. Different properties were updated by the two users. The next time someone browses the English department, they will see both Jane's and John's changes. This method of updating can reduce the number of conflicts that could result in data loss. This approach:  
\* Can't avoid data loss if competing changes are made to the same property.  
\* Is generally not practical in a web app. It requires maintaining significant state in order to keep track of all fetched values and new values.  
Maintaining large amounts of state can affect app performance.  
\* Can increase app complexity compared to concurrency detection on an entity.

- You can let John's change overwrite Jane's change.

The next time someone browses the English department, they will see 9/1/2013 and the fetched \$350,000.00 value. This approach is called a *Client Wins* or *Last in Wins* scenario. (All values from the client take precedence over what's in the data store.) If you don't do any coding for concurrency handling, Client Wins happens automatically.

- You can prevent John's change from being updated in the DB. Typically, the app would:  
\* Display an error message.  
\* Show the current state of the data.  
\* Allow the user to reapply the changes.

This is called a *Store Wins* scenario. (The data-store values take precedence over the values submitted by the client.) You implement the Store Wins scenario in this tutorial. This method ensures that no changes are overwritten without a user being alerted.

## Handling concurrency

When a property is configured as a [concurrency token](#):

- EF Core verifies that property has not been modified after it was fetched. The check occurs when `SaveChanges` or `SaveChangesAsync` is called.
- If the property has been changed after it was fetched, a `DbUpdateConcurrencyException` is thrown.

The DB and data model must be configured to support throwing `DbUpdateConcurrencyException`.

### Detecting concurrency conflicts on a property

Concurrency conflicts can be detected at the property level with the `ConcurrencyCheck` attribute. The attribute can be applied to multiple properties on the model. For more information, see [Data Annotations-ConcurrencyCheck](#).

The `[ConcurrencyCheck]` attribute isn't used in this tutorial.

### Detecting concurrency conflicts on a row

To detect concurrency conflicts, a `rowversion` tracking column is added to the model. `rowversion` :

- Is SQL Server specific. Other databases may not provide a similar feature.
- Is used to determine that an entity has not been changed since it was fetched from the DB.

The DB generates a sequential `rowversion` number that's incremented each time the row is updated. In an `Update` or `Delete` command, the `Where` clause includes the fetched value of `rowversion`. If the row being updated has changed:

- `rowversion` doesn't match the fetched value.
- The `Update` or `Delete` commands don't find a row because the `Where` clause includes the fetched `rowversion`.
- A `DbUpdateConcurrencyException` is thrown.

In EF Core, when no rows have been updated by an `Update` or `Delete` command, a concurrency exception is thrown.

### Add a tracking property to the Department entity

In `Models/Department.cs`, add a tracking property named RowVersion:

```
using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Department
    {
        public int DepartmentID { get; set; }

        [StringLength(50, MinimumLength = 3)]
        public string Name { get; set; }

        [DataType(DataType.Currency)]
        [Column(TypeName = "money")]
        public decimal Budget { get; set; }

        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        [Display(Name = "Start Date")]
        public DateTime StartDate { get; set; }

        public int? InstructorID { get; set; }

        [Timestamp]
        public byte[] RowVersion { get; set; }

        public Instructor Administrator { get; set; }
        public ICollection<Course> Courses { get; set; }
    }
}
```

The `Timestamp` attribute specifies that this column is included in the `Where` clause of `Update` and `Delete`

commands. The attribute is called `Timestamp` because previous versions of SQL Server used a SQL `timestamp` data type before the SQL `rowversion` type replaced it.

The fluent API can also specify the tracking property:

```
modelBuilder.Entity<Department>()
    .Property<byte[]>("RowVersion")
    .IsRowVersion();
```

The following code shows a portion of the T-SQL generated by EF Core when the Department name is updated:

```
SET NOCOUNT ON;
UPDATE [Department] SET [Name] = @p0
WHERE [DepartmentID] = @p1 AND [RowVersion] = @p2;
SELECT [RowVersion]
FROM [Department]
WHERE @@ROWCOUNT = 1 AND [DepartmentID] = @p1;
```

The preceding highlighted code shows the `WHERE` clause containing `RowVersion`. If the DB `RowVersion` doesn't equal the `RowVersion` parameter (`@p2`), no rows are updated.

The following highlighted code shows the T-SQL that verifies exactly one row was updated:

```
SET NOCOUNT ON;
UPDATE [Department] SET [Name] = @p0
WHERE [DepartmentID] = @p1 AND [RowVersion] = @p2;
SELECT [RowVersion]
FROM [Department]
WHERE @@ROWCOUNT = 1 AND [DepartmentID] = @p1;
```

`@@ROWCOUNT` returns the number of rows affected by the last statement. In no rows are updated, EF Core throws a `DbUpdateConcurrencyException`.

You can see the T-SQL EF Core generates in the output window of Visual Studio.

## Update the DB

Adding the `RowVersion` property changes the DB model, which requires a migration.

Build the project. Enter the following in a command window:

```
dotnet ef migrations add RowVersion
dotnet ef database update
```

The preceding commands:

- Adds the `Migrations/{time stamp}_RowVersion.cs` migration file.
- Updates the `Migrations/SchoolContextModelSnapshot.cs` file. The update adds the following highlighted code to the `BuildModel` method:

```

modelBuilder.Entity("ContosoUniversity.Models.Department", b =>
{
    b.Property<int>("DepartmentID")
        .ValueGeneratedOnAdd();

    b.Property<decimal>("Budget")
        .HasColumnType("money");

    b.Property<int?>("InstructorID");

    b.Property<string>("Name")
        .HasMaxLength(50);

    b.Property<byte[]>("RowVersion")
        .IsConcurrencyToken()
        .ValueGeneratedOnAddOrUpdate();

    b.Property<DateTime>("StartDate");

    b.HasKey("DepartmentID");

    b.HasIndex("InstructorID");

    b.ToTable("Department");
});

```

- Runs migrations to update the DB.

## Scaffold the Departments model

- Exit Visual Studio.
- Open a command window in the project directory (The directory that contains the *Program.cs*, *Startup.cs*, and *.csproj* files).
- Run the following command:

```
dotnet aspnet-codegenerator razorpage -m Department -dc SchoolContext -udl -outDir Pages\Departments --referenceScriptLibraries
```

The preceding command scaffolds the `Department` model. Open the project in Visual Studio.

Build the project. The build generates errors like the following:

```
1>Pages/Departments/Index.cshtml.cs(26,37,26,43): error CS1061: 'SchoolContext' does not contain a definition for 'Department' and no extension method 'Department' accepting a first argument of type 'SchoolContext' could be found (are you missing a using directive or an assembly reference?)
```

Globally change `_context.Department` to `_context.Departments` (that is, add an "s" to `Department`). 7 occurrences are found and updated.

### Update the Departments Index page

The scaffolding engine created a `RowVersion` column for the Index page, but that field shouldn't be displayed. In this tutorial, the last byte of the `RowVersion` is displayed to help understand concurrency. The last byte isn't guaranteed to be unique. A real app wouldn't display `RowVersion` or the last byte of `RowVersion`.

Update the Index page:

- Replace `Index` with `Departments`.
- Replace the markup containing `RowVersion` with the last byte of `RowVersion`.

- Replace FirstMidName with FullName.

The following markup shows the updated page:

```

@page
@model ContosoUniversity.Pages.Departments.IndexModel

@{
    ViewData["Title"] = "Departments";
}

<h2>Departments</h2>

<p>
    <a asp-page="Create">Create New</a>
</p>
<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.Department[0].Name)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Department[0].Budget)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Department[0].StartDate)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Department[0].Administrator)
            </th>
            <th>
                RowVersion
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
@foreach (var item in Model.Department) {
        <tr>
            <td>
                @Html.DisplayFor(modelItem => item.Name)
            </td>
            <td>

        </tr>
}
    </tbody>
</table>

```

## Update the Edit page model

Update `pages\departments\edit.cshtml.cs` with the following code:

```
using ContosoUniversity.Data;
using ContosoUniversity.Models;
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using Microsoft.AspNetCore.Mvc.Rendering;
using Microsoft.EntityFrameworkCore;
using System.Linq;
using System.Threading.Tasks;

namespace ContosoUniversity.Pages.Departments
{
    public class EditModel : PageModel
    {
        private readonly ContosoUniversity.Data.SchoolContext _context;

        public EditModel(ContosoUniversity.Data.SchoolContext context)
        {
            _context = context;
        }

        [BindProperty]
        public Department Department { get; set; }
        // Replace ViewData["InstructorID"]
        public SelectList InstructorNameSL { get; set; }

        public async Task<IActionResult> OnGetAsync(int id)
        {
            Department = await _context.Departments
                .Include(d => d.Administrator) // eager loading
                .AsNoTracking() // tracking not required
                .FirstOrDefaultAsync(m => m.DepartmentID == id);

            if (Department == null)
            {
                return NotFound();
            }

            // Use strongly typed data rather than ViewData.
            InstructorNameSL = new SelectList(_context.Instructors,
                "ID", "FirstMidName");

            return Page();
        }

        public async Task<IActionResult> OnPostAsync(int id)
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }

            var departmentToUpdate = await _context.Departments
                .Include(i => i.Administrator)
                .FirstOrDefaultAsync(m => m.DepartmentID == id);

            // null means Department was deleted by another user.
            if (departmentToUpdate == null)
            {
                return await HandleDeletedDepartment();
            }

            // Update the RowVersion to the value when this entity was
            // fetched. If the entity has been updated after it was
            // fetched, RowVersion won't match the DB RowVersion and
            // a DbUpdateConcurrencyException is thrown.
            // A second postback will make them match, unless a new
```

```

        // concurrency issue happens.
        _context.Entry(departmentToUpdate)
            .Property("RowVersion").OriginalValue = Department.RowVersion;

        if (await TryUpdateModelAsync<Department>(
            departmentToUpdate,
            "Department",
            s => s.Name, s => s.StartDate, s => s.Budget, s => s.InstructorID))
    {
        try
        {
            await _context.SaveChangesAsync();
            return RedirectToPage("./Index");
        }
        catch (DbUpdateConcurrencyException ex)
        {
            var exceptionEntry = ex.Entries.Single();
            var clientValues = (Department)exceptionEntry.Entity;
            var databaseEntry = exceptionEntry.GetDatabaseValues();
            if (databaseEntry == null)
            {
                ModelState.AddModelError(string.Empty, "Unable to save. " +
                    "The department was deleted by another user.");
                return Page();
            }

            var dbValues = (Department)databaseEntry.ToObject();
            await setDbErrorMessage(dbValues, clientValues, _context);

            // Save the current RowVersion so next postback
            // matches unless an new concurrency issue happens.
            Department.RowVersion = (byte[])dbValues.RowVersion;
            // Must clear the model error for the next postback.
            ModelState.Remove("Department.RowVersion");
        }
    }

    InstructorNameSL = new SelectList(_context.Instructors,
        "ID", "FullName", departmentToUpdate.InstructorID);

    return Page();
}

private async Task<IActionResult> HandleDeletedDepartment()
{
    Department deletedDepartment = new Department();
    // ModelState contains the posted data because of the deletion error and will override the
    Department instance values when displaying Page().
    ModelState.AddModelError(string.Empty,
        "Unable to save. The department was deleted by another user.");
    InstructorNameSL = new SelectList(_context.Instructors, "ID", "FullName",
    Department.InstructorID);
    return Page();
}

private async Task setDbErrorMessage(Department dbValues,
    Department clientValues, SchoolContext context)
{

    if (dbValues.Name != clientValues.Name)
    {
        ModelState.AddModelError("Department.Name",
            $"Current value: {dbValues.Name}");
    }
    if (dbValues.Budget != clientValues.Budget)
    {
        ModelState.AddModelError("Department.Budget",
            $"Current value: {dbValues.Budget:c}");
    }
}

```

```

        }

        if (dbValues.StartDate != clientValues.StartDate)
        {
            ModelState.AddModelError("Department.StartDate",
                $"Current value: {dbValues.StartDate:d}");
        }
        if (dbValues.InstructorID != clientValues.InstructorID)
        {
            Instructor dbInstructor = await _context.Instructors
                .FindAsync(dbValues.InstructorID);
            ModelState.AddModelError("Department.InstructorID",
                $"Current value: {dbInstructor?.FullName}");
        }
    }

    ModelState.AddModelError(string.Empty,
        "The record you attempted to edit "
        + "was modified by another user after you. The "
        + "edit operation was canceled and the current values in the database "
        + "have been displayed. If you still want to edit this record, click "
        + "the Save button again.");
}
}
}

```

To detect a concurrency issue, the `OriginalValue` is updated with the `rowVersion` value from the entity it was fetched. EF Core generates a SQL UPDATE command with a WHERE clause containing the original `RowVersion` value. If no rows are affected by the UPDATE command (no rows have the original `RowVersion` value), a `DbUpdateConcurrencyException` exception is thrown.

```

public async Task<IActionResult> OnPostAsync(int id)
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    var departmentToUpdate = await _context.Departments
        .Include(i => i.Administrator)
        .FirstOrDefaultAsync(m => m.DepartmentID == id);

    // null means Department was deleted by another user.
    if (departmentToUpdate == null)
    {
        return await HandleDeletedDepartment();
    }

    // Update the RowVersion to the value when this entity was
    // fetched. If the entity has been updated after it was
    // fetched, RowVersion won't match the DB RowVersion and
    // a DbUpdateConcurrencyException is thrown.
    // A second postback will make them match, unless a new
    // concurrency issue happens.
    _context.Entry(departmentToUpdate)
        .Property("RowVersion").OriginalValue = Department.RowVersion;
}

```

In the preceding code, `Department.RowVersion` is the value when the entity was fetched. `OriginalValue` is the value in the DB when `FirstOrDefaultAsync` was called in this method.

The following code gets the client values (the values posted to this method) and the DB values:

```

try
{
    await _context.SaveChangesAsync();
    return RedirectToPage("./Index");
}
catch (DbUpdateConcurrencyException ex)
{
    var exceptionEntry = ex.Entries.Single();
    var clientValues = (Department)exceptionEntry.Entity;
    var databaseEntry = exceptionEntry.GetDatabaseValues();
    if (databaseEntry == null)
    {
        ModelState.AddModelError(string.Empty, "Unable to save. " +
            "The department was deleted by another user.");
        return Page();
    }

    var dbValues = (Department)databaseEntry.ToObject();
    await setDbErrorMessage(dbValues, clientValues, _context);

    // Save the current RowVersion so next postback
    // matches unless a new concurrency issue happens.
    Department.RowVersion = (byte[])dbValues.RowVersion;
    // Must clear the model error for the next postback.
    ModelState.Remove("Department.RowVersion");
}

```

The following code adds a custom error message for each column that has DB values different from what was posted to `OnPostAsync`:

```

private async Task setDbErrorMessage(Department dbValues,
    Department clientValues, SchoolContext context)
{

    if (dbValues.Name != clientValues.Name)
    {
        ModelState.AddModelError("Department.Name",
            $"Current value: {dbValues.Name}");
    }
    if (dbValues.Budget != clientValues.Budget)
    {
        ModelState.AddModelError("Department.Budget",
            $"Current value: {dbValues.Budget:c}");
    }
    if (dbValues.StartDate != clientValues.StartDate)
    {
        ModelState.AddModelError("Department.StartDate",
            $"Current value: {dbValues.StartDate:d}");
    }
    if (dbValues.InstructorID != clientValues.InstructorID)
    {
        Instructor dbInstructor = await _context.Instructors
            .FindAsync(dbValues.InstructorID);
        ModelState.AddModelError("Department.InstructorID",
            $"Current value: {dbInstructor?.FullName}");
    }

    ModelState.AddModelError(string.Empty,
        "The record you attempted to edit " +
        "was modified by another user after you. The " +
        "edit operation was canceled and the current values in the database " +
        "have been displayed. If you still want to edit this record, click " +
        "the Save button again.");
}

```

The following highlighted code sets the `RowVersion` value to the new value retrieved from the DB. The next time the user clicks **Save**, only concurrency errors that happen since the last display of the Edit page will be caught.

```
try
{
    await _context.SaveChangesAsync();
    return RedirectToPage("./Index");
}
catch (DbUpdateConcurrencyException ex)
{
    var exceptionEntry = ex.Entries.Single();
    var clientValues = (Department)exceptionEntry.Entity;
    var databaseEntry = exceptionEntry.GetDatabaseValues();
    if (databaseEntry == null)
    {
        ModelState.AddModelError(string.Empty, "Unable to save. " +
            "The department was deleted by another user.");
        return Page();
    }

    var dbValues = (Department)databaseEntry.ToObject();
    await setDbErrorMessage(dbValues, clientValues, _context);

    // Save the current RowVersion so next postback
    // matches unless a new concurrency issue happens.
    Department.RowVersion = (byte[])dbValues.RowVersion;
    // Must clear the model error for the next postback.
    ModelState.Remove("Department.RowVersion");
}
```

The `ModelState.Remove` statement is required because `ModelState` has the old `RowVersion` value. In the Razor Page, the `ModelState` value for a field takes precedence over the model property values when both are present.

## Update the Edit page

Update `Pages/Departments/Edit.cshtml` with the following markup:

```

@page "{id:int}"
@model ContosoUniversity.Pages.Departments.EditModel
 @{
     ViewData["Title"] = "Edit";
 }
<h2>Edit</h2>
<h4>Department</h4>
<hr />
<div class="row">
    <div class="col-md-4">
        <form method="post">
            <div asp-validation-summary="ModelOnly" class="text-danger"></div>
            <input type="hidden" asp-for="Department.DepartmentID" />
            <input type="hidden" asp-for="Department.RowVersion" />
            <div class="form-group">
                <label>RowVersion</label>
                @Model.Department.RowVersion[7]
            </div>
            <div class="form-group">
                <label asp-for="Department.Name" class="control-label"></label>
                <input asp-for="Department.Name" class="form-control" />
                <span asp-validation-for="Department.Name" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Department.Budget" class="control-label"></label>
                <input asp-for="Department.Budget" class="form-control" />
                <span asp-validation-for="Department.Budget" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Department.StartDate" class="control-label"></label>
                <input asp-for="Department.StartDate" class="form-control" />
                <span asp-validation-for="Department.StartDate" class="text-danger">
                    </span>
            </div>
            <div class="form-group">
                <label class="control-label">Instructor</label>
                <select asp-for="Department.InstructorID" class="form-control" asp-items="@Model.InstructorNameSL"></select>
                <span asp-validation-for="Department.InstructorID" class="text-danger">
                    </span>
            </div>
            <div class="form-group">
                <input type="submit" value="Save" class="btn btn-default" />
            </div>
        </form>
    </div>
</div>
<a asp-page=".~/Index">Back to List</a>
</div>
@section Scripts {
    @{await Html.RenderPartialAsync("_ValidationScriptsPartial");}
}

```

The preceding markup:

- Updates the `page` directive from `@page` to `@page "{id:int}"`.
- Adds a hidden row version. `RowVersion` must be added so post back binds the value.
- Displays the last byte of `RowVersion` for debugging purposes.
- Replaces `ViewData` with the strongly-typed `InstructorNameSL`.

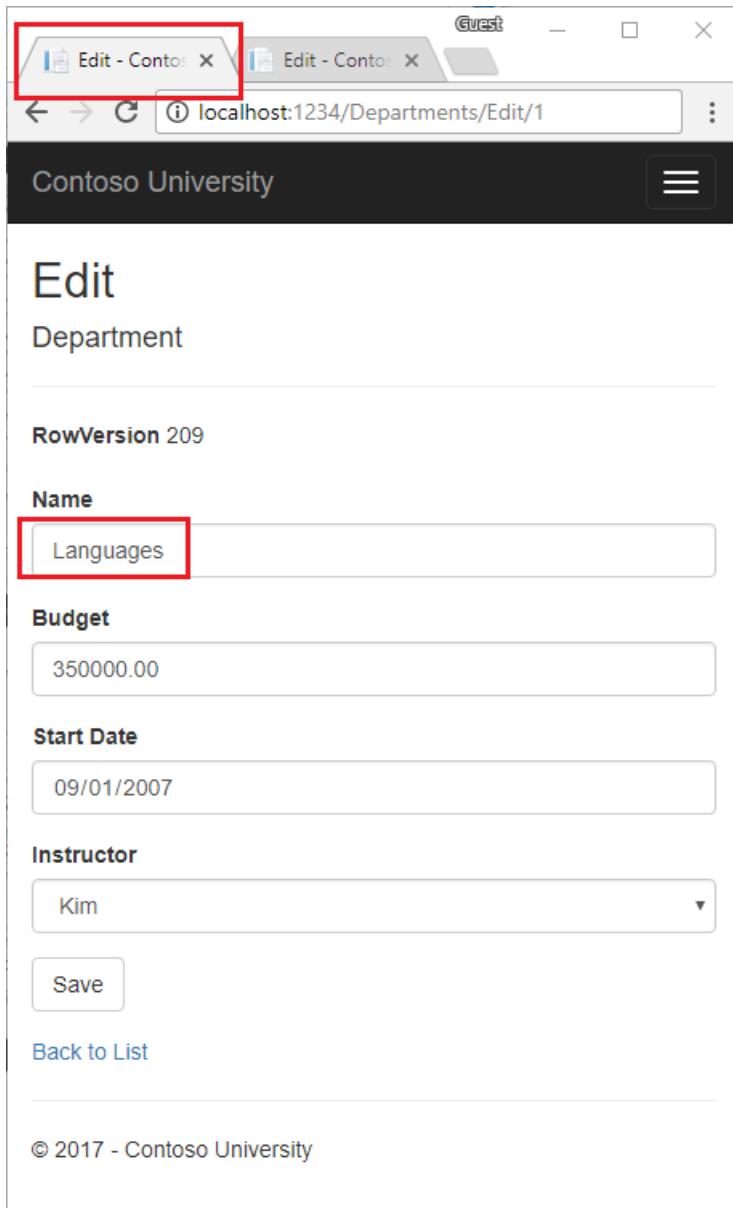

## Test concurrency conflicts with the Edit page

Open two browsers instances of Edit on the English department:

- Run the app and select Departments.
- Right-click the **Edit** hyperlink for the English department and select **Open in new tab**.
- In the first tab, click the **Edit** hyperlink for the English department.

The two browser tabs display the same information.

Change the name in the first browser tab and click **Save**.

The screenshot shows a web browser window with two tabs. The active tab is titled "Edit - Contoso" and displays the "Edit Department" page for the "Languages" department. The "Name" field is highlighted with a red box and contains the value "Languages". The second tab is also titled "Edit - Contoso" and shows the same page, but the "Name" field contains the value "English". The browser address bar shows "localhost:1234/Departments/Edit/1".

**Edit**  
Department

RowVersion 209

**Name**  
Languages

**Budget**  
350000.00

**Start Date**  
09/01/2007

**Instructor**  
Kim

**Save**

[Back to List](#)

© 2017 - Contoso University

The browser shows the Index page with the changed value and updated rowVersion indicator. Note the updated rowVersion indicator, it's displayed on the second postback in the other tab.

Change a different field in the second browser tab.

Screenshot of a web browser showing the 'Edit - Contoso' page for a department. The browser title bar says 'Edit - Contoso'. The address bar shows 'localhost:1234/Departments/Edit/1'. The page header says 'Contoso University'. The main content area has a heading 'Edit' and 'Department'. It displays a 'RowVersion' of 209. There are four input fields: 'Name' (value: English), 'Budget' (value: 5000000, highlighted with a red box), 'Start Date' (value: 09/01/2007), and 'Instructor' (value: Kim). A 'Save' button is present. Below the form is a link 'Back to List' and a copyright notice '© 2017 - Contoso University'.

Click **Save**. You see error messages for all fields that don't match the DB values:

Guest

Departments Edit - Contoso University

localhost:1234/Departments/Edit/1

## Edit Department

The record you attempted to edit was modified by another user after you. The edit operation was canceled and the current values in the database have been displayed. If you still want to edit this record, click the Save button again.

**RowVersion** 21

**Name**

English

Current value: Languages

**Budget**

5000000

Current value: \$350,000.00

**Start Date**

09/01/2007

**Instructor**

Abercrombie, Kim

**Save**

[Back to List](#)

Click **Save** again. The value you entered in the second browser tab is saved. You see the saved values in the Index page.

## Update the Delete page

Update the Delete page model with the following code:

```
using ContosoUniversity.Models;
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using Microsoft.EntityFrameworkCore;
using System.Threading.Tasks;

namespace ContosoUniversity.Pages.Departments
{
    public class DeleteModel : PageModel
    {
        private readonly ContosoUniversity.Data.SchoolContext _context;
```

The Delete page detects concurrency conflicts when the entity has changed after it was fetched.

`Department.RowVersion` is the row version when the entity was fetched. When EF Core creates the SQL DELETE command, it includes a WHERE clause with `RowVersion`. If the SQL DELETE command results in zero rows affected:

- The `RowVersion` in the SQL DELETE command doesn't match `RowVersion` in the DB.
  - A `DbUpdateConcurrencyException` exception is thrown.
  - `OnGetAsync` is called with the `concurrencyError`.

## Update the Delete page

Update *Pages/Departments/Delete.cshtml* with the following code:

```
@page "{id:int}"
@model ContosoUniversity.Pages.Departments.DeleteModel

@{
    ViewData["Title"] = "Delete";
}

## Delete

@Model.ConcurrencyErrorMessage

### Are you sure you want to delete this?

#### Department

---

<dt>
        @Html.DisplayNameFor(model => model.Department.Name)
    </dt>
    <dd>
        @Html.DisplayFor(model => model.Department.Name)
    </dd>
    <dt>
        @Html.DisplayNameFor(model => model.Department.Budget)
    </dt>
    <dd>
        @Html.DisplayFor(model => model.Department.Budget)
    </dd>
    <dt>
        @Html.DisplayNameFor(model => model.Department.StartDate)
    </dt>
    <dd>
        @Html.DisplayFor(model => model.Department.StartDate)
    </dd>
    <dt>
        @Html.DisplayNameFor(model => model.Department.RowVersion)
    </dt>
    <dd>
        @Html.DisplayFor(model => model.Department.RowVersion[7])
    </dd>
    <dt>
        @Html.DisplayNameFor(model => model.DepartmentAdministrator)
    </dt>
    <dd>
        @Html.DisplayFor(model => model.DepartmentAdministrator.FullName)
    </dd>

<form method="post">
    <input type="hidden" asp-for="Department.DepartmentID" />
    <input type="hidden" asp-for="Department.RowVersion" />
    <div class="form-actions no-color">
        <input type="submit" value="Delete" class="btn btn-default" /> |
        <a asp-page=".~/Index">Back to List</a>
    </div>
</form>

```

The preceding markup makes the following changes:

- Updates the `page` directive from `@page` to `@page "{id:int}"`.
- Adds an error message.

- Replaces FirstMidName with FullName in the **Administrator** field.
- Changes `RowVersion` to display the last byte.
- Adds a hidden row version. `RowVersion` must be added so post back binds the value.

## Test concurrency conflicts with the Delete page

Create a test department.

Open two browsers instances of Delete on the test department:

- Run the app and select Departments.
- Right-click the **Delete** hyperlink for the test department and select **Open in new tab**.
- Click the **Edit** hyperlink for the test department.

The two browser tabs display the same information.

Change the budget in the first browser tab and click **Save**.

The browser shows the Index page with the changed value and updated rowVersion indicator. Note the updated rowVersion indicator, it's displayed on the second postback in the other tab.

Delete the test department from the second tab. A concurrency error is display with the current values from the DB. Clicking **Delete** deletes the entity, unless `RowVersion` has been updated.department has been deleted.

See [Inheritance](#) on how to inherit a data model.

# ASP.NET Core MVC with EF Core - tutorial series

6/21/2018 • 2 minutes to read • [Edit Online](#)

This tutorial teaches ASP.NET Core MVC and Entity Framework Core with controllers and views. Razor Pages is a new alternative in ASP.NET Core 2.0, a page-based programming model that makes building web UI easier and more productive. We recommend the [Razor Pages](#) tutorial over the MVC version. The Razor Pages tutorial:

- Is easier to follow.
- Provides more EF Core best practices.
- Uses more efficient queries.
- Is more current with the latest API.
- Covers more features.
- Is the preferred approach for new application development.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub issue](#).

1. [Get started](#)
2. [Create, Read, Update, and Delete operations](#)
3. [Sorting, filtering, paging, and grouping](#)
4. [Migrations](#)
5. [Create a complex data model](#)
6. [Reading related data](#)
7. [Updating related data](#)
8. [Handle concurrency conflicts](#)
9. [Inheritance](#)
10. [Advanced topics](#)

# ASP.NET Core MVC with Entity Framework Core - Tutorial 1 of 10

6/28/2018 • 22 minutes to read • [Edit Online](#)

This tutorial has not been upgraded to ASP.NET Core 2.1. The ASP.NET Core 2.0 version of this tutorial is available by selecting **ASP.NET Core 2.0** above the table of contents or at the top of the page:

The ASP.NET Core 2.1 Razor Pages version of this tutorial has many improvements over the 2.0 version.

The 2.0 tutorial teaches ASP.NET Core MVC and Entity Framework Core with controllers and views. Razor Pages is a page-based programming model that makes building web UI easier and more productive. We recommend the [Razor Pages](#) tutorial over the MVC version. The Razor Pages tutorial:

- Is easier to follow. For example, the scaffolding code has been significantly simplified.
- Provides more EF Core best practices.
- Uses more efficient queries.
- Is more current with the latest API.
- Covers more features.
- Is the preferred approach for new application development.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub discussion](#).

By [Tom Dykstra](#) and [Rick Anderson](#)

This tutorial teaches ASP.NET Core MVC and Entity Framework Core with controllers and views. Razor Pages is a new alternative in ASP.NET Core 2.0, a page-based programming model that makes building web UI easier and more productive. We recommend the [Razor Pages](#) tutorial over the MVC version. The Razor Pages tutorial:

- Is easier to follow.
- Provides more EF Core best practices.
- Uses more efficient queries.
- Is more current with the latest API.
- Covers more features.
- Is the preferred approach for new application development.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub issue](#).

The Contoso University sample web application demonstrates how to create ASP.NET Core 2.0 MVC web applications using Entity Framework (EF) Core 2.0 and Visual Studio 2017.

The sample application is a web site for a fictional Contoso University. It includes functionality such as student admission, course creation, and instructor assignments. This is the first in a series of tutorials that explain how to build the Contoso University sample application from scratch.

[Download or view the completed application](#).

EF Core 2.0 is the latest version of EF but doesn't yet have all the features of EF 6.x. For information about how to choose between EF 6.x and EF Core, see [EF Core vs. EF6.x](#). If you choose EF 6.x, see [the previous version of this tutorial series](#).

## NOTE

For the ASP.NET Core 1.1 version of this tutorial, see the [VS 2017 Update 2 version of this tutorial in PDF format](#).

## Prerequisites

Install **one** of the following:

- CLI tooling: Windows, Linux, or macOS: [.NET Core SDK 2.0 or later](#)
- IDE/editor tooling
  - Windows: [Visual Studio for Windows](#)
    - **ASP.NET and web development** workload
    - **.NET Core cross-platform development** workload
  - Linux: [Visual Studio Code](#)
  - macOS: [Visual Studio for Mac](#)

## Troubleshooting

If you run into a problem you can't resolve, you can generally find the solution by comparing your code to the [completed project](#). For a list of common errors and how to solve them, see [the Troubleshooting section of the last tutorial in the series](#). If you don't find what you need there, you can post a question to StackOverflow.com for [ASP.NET Core](#) or [EF Core](#).

## TIP

This is a series of 10 tutorials, each of which builds on what is done in earlier tutorials. Consider saving a copy of the project after each successful tutorial completion. Then if you run into problems, you can start over from the previous tutorial instead of going back to the beginning of the whole series.

## The Contoso University web application

The application you'll be building in these tutorials is a simple university web site.

Users can view and update student, course, and instructor information. Here are a few of the screens you'll create.

Last Name	First Mid Name	Enrollment Date	
Alexander	Carson	9/1/2005 12:00:00 AM	Edit   Details   Delete
Alonso	Meredith	9/1/2002 12:00:00 AM	Edit   Details   Delete
Anand	Arturo	9/1/2003 12:00:00 AM	Edit   Details   Delete
Barzdukas	Gytis	9/1/2002 12:00:00 AM	Edit   Details   Delete

EnrollmentDate  
2005-09-01T00:00:00.000

FirstMidName  
Carson

Last Name  
Alexander

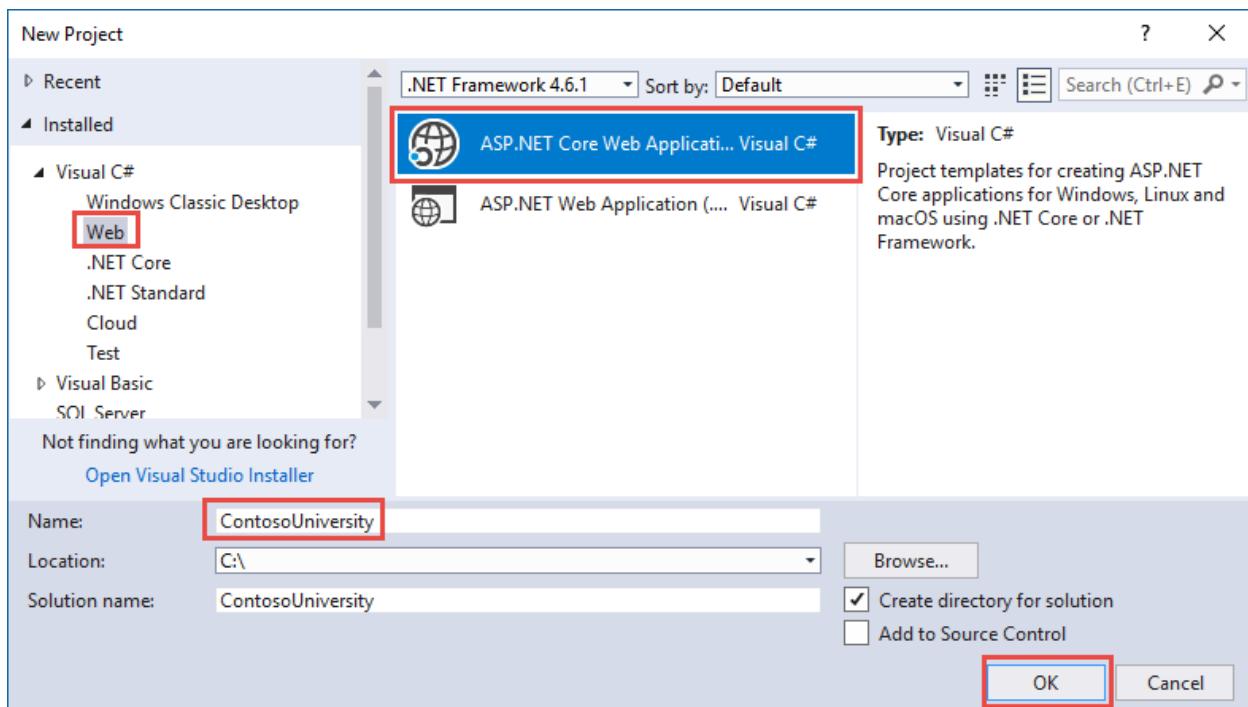

Save

The UI style of this site has been kept close to what's generated by the built-in templates, so that the tutorial can focus mainly on how to use the Entity Framework.

## Create an ASP.NET Core MVC web application

Open Visual Studio and create a new ASP.NET Core C# web project named "ContosoUniversity".

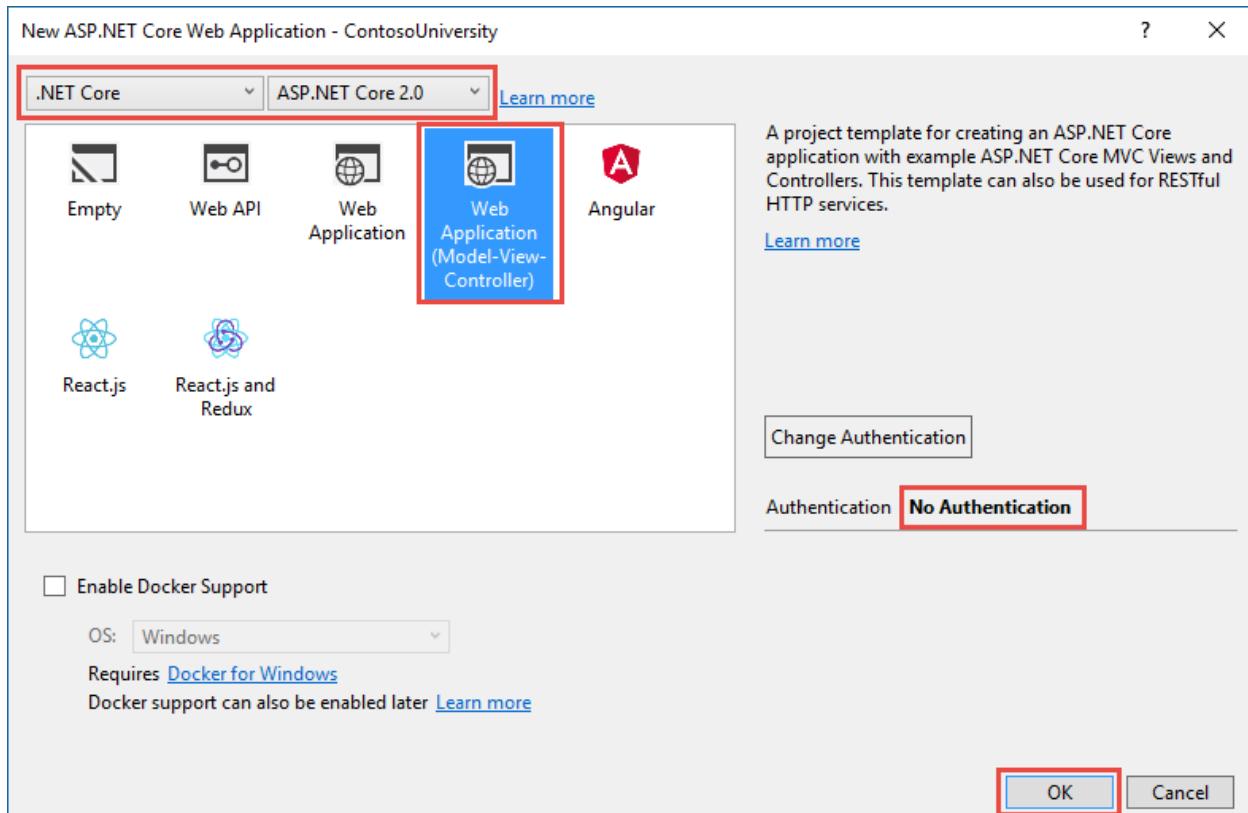

- From the **File** menu, select **New > Project**.
- From the left pane, select **Installed > Visual C# > Web**.
- Select the **ASP.NET Core Web Application** project template.
- Enter **ContosoUniversity** as the name and click **OK**.

- Wait for the **New ASP.NET Core Web Application (.NET Core)** dialog to appear
- Select **ASP.NET Core 2.0** and the **Web Application (Model-View-Controller)** template.

**Note:** This tutorial requires ASP.NET Core 2.0 and EF Core 2.0 or later -- make sure that **ASP.NET Core 1.1** isn't selected.

- Make sure **Authentication** is set to **No Authentication**.
- Click **OK**

## Set up the site style

A few simple changes will set up the site menu, layout, and home page.

Open Views/Shared/\_Layout.cshtml and make the following changes:

- Change each occurrence of "ContosoUniversity" to "Contoso University". There are three occurrences.
- Add menu entries for **Students**, **Courses**, **Instructors**, and **Departments**, and delete the **Contact** menu entry.

The changes are highlighted.

```

    </script>
    <script src="~/js/site.min.js" asp-append-version="true"></script>
</environment>

    @RenderSection("Scripts", required: false)
</body>
</html>

```

In *Views/Home/Index.cshtml*, replace the contents of the file with the following code to replace the text about ASP.NET and MVC with text about this application:

```

@{
    ViewData["Title"] = "Home Page";
}

<div class="jumbotron">
    <h1>Contoso University</h1>
</div>
<div class="row">
    <div class="col-md-4">
        <h2>Welcome to Contoso University</h2>
        <p>
            Contoso University is a sample application that
            demonstrates how to use Entity Framework Core in an
            ASP.NET Core MVC web application.
        </p>
    </div>
    <div class="col-md-4">
        <h2>Build it from scratch</h2>
        <p>You can build the application by following the steps in a series of tutorials.</p>
        <p><a class="btn btn-default" href="https://docs.asp.net/en/latest/data/ef-mvc/intro.html">See the
        tutorial &raquo;</a></p>
    </div>
    <div class="col-md-4">
        <h2>Download it</h2>
        <p>You can download the completed project from GitHub.</p>
        <p><a class="btn btn-default" href="https://github.com/aspnet/Docs/tree/master/aspnetcore/data/ef-
        mvc/intro/samples/cu-final">See project source code &raquo;</a></p>
    </div>
</div>

```

Press CTRL+F5 to run the project or choose **Debug > Start Without Debugging** from the menu. You see the home page with tabs for the pages you'll create in these tutorials.

The screenshot shows a web browser window with the title bar "Home Page - Contoso U X". The address bar displays "localhost:5813". The page content is the Contoso University homepage, featuring a large header "Contoso University", a sub-header "Welcome to Contoso University", a paragraph about the application, and sections for "Build it from scratch" and "Download it". Each section includes a button labeled "See the tutorial »" or "See project source code »". At the bottom, there is a copyright notice "© 2016 - Contoso University".

# Contoso University

## Welcome to Contoso University

Contoso University is a sample application that demonstrates how to use Entity Framework Core 1.0 in an ASP.NET Core MVC 1.0 web application.

### Build it from scratch

You can build the application by following the steps in a series of tutorials.

[See the tutorial »](#)

### Download it

You can download the completed project from GitHub.

[See project source code »](#)

© 2016 - Contoso University

## Entity Framework Core NuGet packages

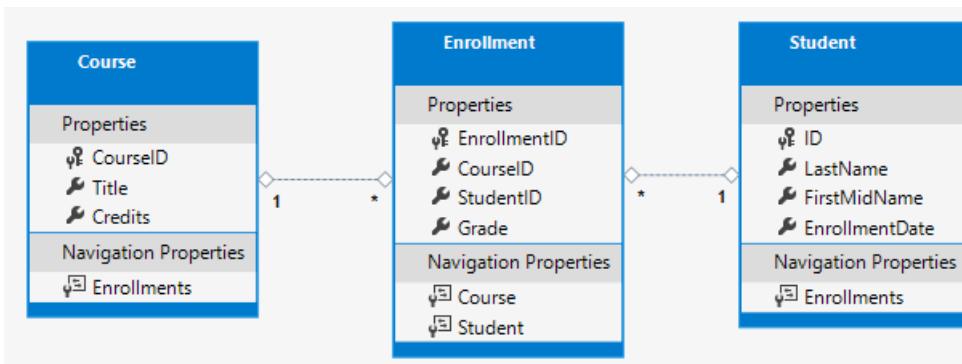

To add EF Core support to a project, install the database provider that you want to target. This tutorial uses SQL Server, and the provider package is [Microsoft.EntityFrameworkCore.SqlServer](#). This package is included in the [Microsoft.AspNetCore.All](#) metapackage, so you don't have to install it.

This package and its dependencies (`Microsoft.EntityFrameworkCore` and `Microsoft.EntityFrameworkCore.Relational`) provide runtime support for EF. You'll add a tooling package later, in the [Migrations](#) tutorial.

For information about other database providers that are available for Entity Framework Core, see [Database providers](#).

## Create the data model

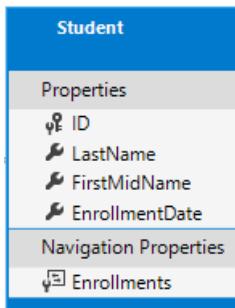

Next you'll create entity classes for the Contoso University application. You'll start with the following three entities.

There's a one-to-many relationship between `Student` and `Enrollment` entities, and there's a one-to-many relationship between `Course` and `Enrollment` entities. In other words, a student can be enrolled in any number of courses, and a course can have any number of students enrolled in it.

In the following sections you'll create a class for each one of these entities.

### The Student entity

In the `Models` folder, create a class file named `Student.cs` and replace the template code with the following code.

```

using System;
using System.Collections.Generic;

namespace ContosoUniversity.Models
{
    public class Student
    {
        public int ID { get; set; }
        public string LastName { get; set; }
        public string FirstMidName { get; set; }
        public DateTime EnrollmentDate { get; set; }

        public ICollection<Enrollment> Enrollments { get; set; }
    }
}

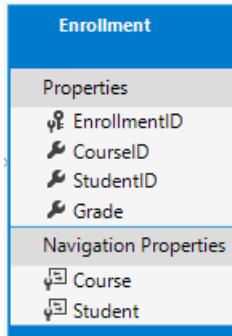

```

The `ID` property will become the primary key column of the database table that corresponds to this class. By default, the Entity Framework interprets a property that's named `ID` or `classnameID` as the primary key.

The `Enrollments` property is a navigation property. Navigation properties hold other entities that are related to this entity. In this case, the `Enrollments` property of a `student` entity will hold all of the `Enrollment` entities that are related to that `student` entity. In other words, if a given Student row in the database has two related Enrollment rows (rows that contain that student's primary key value in their `StudentID` foreign key column), that `Student` entity's `Enrollments` navigation property will contain those two `Enrollment` entities.

If a navigation property can hold multiple entities (as in many-to-many or one-to-many relationships), its type must be a list in which entries can be added, deleted, and updated, such as `ICollection<T>`. You can specify `ICollection<T>` or a type such as `List<T>` or `HashSet<T>`. If you specify `ICollection<T>`, EF creates a `HashSet<T>` collection by default.

## The Enrollment entity

In the *Models* folder, create *Enrollment.cs* and replace the existing code with the following code:

```
namespace ContosoUniversity.Models
{
    public enum Grade
    {
        A, B, C, D, F
    }

    public class Enrollment
    {
        public int EnrollmentID { get; set; }
        public int CourseID { get; set; }
        public int StudentID { get; set; }
        public Grade? Grade { get; set; }

        public Course Course { get; set; }
        public Student Student { get; set; }
    }
}
```

The `EnrollmentID` property will be the primary key; this entity uses the `classnameID` pattern instead of `ID` by itself as you saw in the `student` entity. Ordinarily you would choose one pattern and use it throughout your data model. Here, the variation illustrates that you can use either pattern. In a [later tutorial](#), you'll see how using ID without classname makes it easier to implement inheritance in the data model.

The `Grade` property is an `enum`. The question mark after the `Grade` type declaration indicates that the `Grade` property is nullable. A grade that's null is different from a zero grade -- null means a grade isn't known or hasn't been assigned yet.

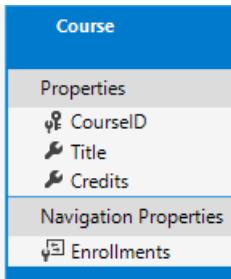

The `StudentID` property is a foreign key, and the corresponding navigation property is `Student`. An `Enrollment` entity is associated with one `Student` entity, so the property can only hold a single `student` entity (unlike the `Student.Enrollments` navigation property you saw earlier, which can hold multiple `Enrollment` entities).

The `CourseID` property is a foreign key, and the corresponding navigation property is `Course`. An `Enrollment` entity is associated with one `Course` entity.

Entity Framework interprets a property as a foreign key property if it's named

`<navigation property name><primary key property name>` (for example, `StudentID` for the `Student` navigation property since the `Student` entity's primary key is `ID`). Foreign key properties can also be named simply `<primary key property name>` (for example, `courseID` since the `Course` entity's primary key is `CourseID`).

## The Course entity

In the *Models* folder, create *Course.cs* and replace the existing code with the following code:

```
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Course
    {
        [DatabaseGenerated(DatabaseGeneratedOption.None)]
        public int CourseID { get; set; }
        public string Title { get; set; }
        public int Credits { get; set; }

        public ICollection<Enrollment> Enrollments { get; set; }
    }
}
```

The `Enrollments` property is a navigation property. A `Course` entity can be related to any number of `Enrollment` entities.

We'll say more about the `DatabaseGenerated` attribute in a [later tutorial](#) in this series. Basically, this attribute lets you enter the primary key for the course rather than having the database generate it.

## Create the Database Context

The main class that coordinates Entity Framework functionality for a given data model is the database context class. You create this class by deriving from the `Microsoft.EntityFrameworkCore.DbContext` class. In your code you specify which entities are included in the data model. You can also customize certain Entity Framework behavior. In this project, the class is named `SchoolContext`.

In the project folder, create a folder named *Data*.

In the *Data* folder create a new class file named *SchoolContext.cs*, and replace the template code with the following code:

```

using ContosoUniversity.Models;
using Microsoft.EntityFrameworkCore;

namespace ContosoUniversity.Data
{
    public class SchoolContext : DbContext
    {
        public SchoolContext(DbContextOptions<SchoolContext> options) : base(options)
        {

        }

        public DbSet<Course> Courses { get; set; }
        public DbSet<Enrollment> Enrollments { get; set; }
        public DbSet<Student> Students { get; set; }
    }
}

```

This code creates a `DbSet` property for each entity set. In Entity Framework terminology, an entity set typically corresponds to a database table, and an entity corresponds to a row in the table.

You could've omitted the `DbSet<Enrollment>` and `DbSet<Course>` statements and it would work the same. The Entity Framework would include them implicitly because the `Student` entity references the `Enrollment` entity and the `Enrollment` entity references the `Course` entity.

When the database is created, EF creates tables that have names the same as the `DbSet` property names. Property names for collections are typically plural (Students rather than Student), but developers disagree about whether table names should be pluralized or not. For these tutorials you'll override the default behavior by specifying singular table names in the `DbContext`. To do that, add the following highlighted code after the last `DbSet` property.

```

using ContosoUniversity.Models;
using Microsoft.EntityFrameworkCore;

namespace ContosoUniversity.Data
{
    public class SchoolContext : DbContext
    {
        public SchoolContext(DbContextOptions<SchoolContext> options) : base(options)
        {

        }

        public DbSet<Course> Courses { get; set; }
        public DbSet<Enrollment> Enrollments { get; set; }
        public DbSet<Student> Students { get; set; }

        protected override void OnModelCreating(ModelBuilder modelBuilder)
        {
            modelBuilder.Entity<Course>().ToTable("Course");
            modelBuilder.Entity<Enrollment>().ToTable("Enrollment");
            modelBuilder.Entity<Student>().ToTable("Student");
        }
    }
}

```

## Register the context with dependency injection

ASP.NET Core implements [dependency injection](#) by default. Services (such as the EF database context) are registered with dependency injection during application startup. Components that require these services (such as MVC controllers) are provided these services via constructor parameters. You'll see the controller constructor code that gets a context instance later in this tutorial.

To register `SchoolContext` as a service, open `Startup.cs`, and add the highlighted lines to the `ConfigureServices` method.

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddDbContext<SchoolContext>(options =>
        options.UseSqlServer(Configuration.GetConnectionString("DefaultConnection")));

    services.AddMvc();
}
```

The name of the connection string is passed in to the context by calling a method on a `DbContextOptionsBuilder` object. For local development, the [ASP.NET Core configuration system](#) reads the connection string from the `appsettings.json` file.

Add `using` statements for `ContosoUniversity.Data` and `Microsoft.EntityFrameworkCore` namespaces, and then build the project.

```
using ContosoUniversity.Data;
using Microsoft.EntityFrameworkCore;
```

Open the `appsettings.json` file and add a connection string as shown in the following example.

```
{
  "ConnectionStrings": {
    "DefaultConnection": "Server=(localdb)\\mssqllocaldb;Database=ContosoUniversity1;Trusted_Connection=True;MultipleActiveResultSets=true"
  },
  "Logging": {
    "IncludeScopes": false,
    "LogLevel": {
      "Default": "Warning"
    }
  }
}
```

## SQL Server Express LocalDB

The connection string specifies a SQL Server LocalDB database. LocalDB is a lightweight version of the SQL Server Express Database Engine and is intended for application development, not production use. LocalDB starts on demand and runs in user mode, so there's no complex configuration. By default, LocalDB creates `.mdf` database files in the `C:/Users/<user>` directory.

## Add code to initialize the database with test data

The Entity Framework will create an empty database for you. In this section, you write a method that's called after the database is created in order to populate it with test data.

Here you'll use the `EnsureCreated` method to automatically create the database. In a [later tutorial](#) you'll see how to handle model changes by using Code First Migrations to change the database schema instead of dropping and re-creating the database.

In the `Data` folder, create a new class file named `DbInitializer.cs` and replace the template code with the following code, which causes a database to be created when needed and loads test data into the new database.

```
using ContosoUniversity.Models;
using System;
using System.Linq;
```

```

namespace ContosoUniversity.Data
{
    public static class DbInitializer
    {
        public static void Initialize(SchoolContext context)
        {
            context.Database.EnsureCreated();

            // Look for any students.
            if (context.Students.Any())
            {
                return; // DB has been seeded
            }

            var students = new Student[]
            {
                new Student{FirstMidName="Carson",LastName="Alexander",EnrollmentDate=DateTime.Parse("2005-09-01")},
                new Student{FirstMidName="Meredith",LastName="Alonso",EnrollmentDate=DateTime.Parse("2002-09-01")},
                new Student{FirstMidName="Arturo",LastName="Anand",EnrollmentDate=DateTime.Parse("2003-09-01")},
                new Student{FirstMidName="Gytis",LastName="Barzdukas",EnrollmentDate=DateTime.Parse("2002-09-01")},
                new Student{FirstMidName="Yan",LastName="Li",EnrollmentDate=DateTime.Parse("2002-09-01")},
                new Student{FirstMidName="Peggy",LastName="Justice",EnrollmentDate=DateTime.Parse("2001-09-01")},
                new Student{FirstMidName="Laura",LastName="Norman",EnrollmentDate=DateTime.Parse("2003-09-01")},
                new Student{FirstMidName="Nino",LastName="Olivetto",EnrollmentDate=DateTime.Parse("2005-09-01")}
            };
            foreach (Student s in students)
            {
                context.Students.Add(s);
            }
            context.SaveChanges();

            var courses = new Course[]
            {
                new Course{CourseID=1050,Title="Chemistry",Credits=3},
                new Course{CourseID=4022,Title="Microeconomics",Credits=3},
                new Course{CourseID=4041,Title="Macroeconomics",Credits=3},
                new Course{CourseID=1045,Title="Calculus",Credits=4},
                new Course{CourseID=3141,Title="Trigonometry",Credits=4},
                new Course{CourseID=2021,Title="Composition",Credits=3},
                new Course{CourseID=2042,Title="Literature",Credits=4}
            };
            foreach (Course c in courses)
            {
                context.Courses.Add(c);
            }
            context.SaveChanges();

            var enrollments = new Enrollment[]
            {
                new Enrollment{StudentID=1,CourseID=1050,Grade=Grade.A},
                new Enrollment{StudentID=1,CourseID=4022,Grade=Grade.C},
                new Enrollment{StudentID=1,CourseID=4041,Grade=Grade.B},
                new Enrollment{StudentID=2,CourseID=1045,Grade=Grade.B},
                new Enrollment{StudentID=2,CourseID=3141,Grade=Grade.F},
                new Enrollment{StudentID=2,CourseID=2021,Grade=Grade.F},
                new Enrollment{StudentID=3,CourseID=1050},
                new Enrollment{StudentID=4,CourseID=1050},
                new Enrollment{StudentID=4,CourseID=4022,Grade=Grade.F},
                new Enrollment{StudentID=5,CourseID=4041,Grade=Grade.C},
                new Enrollment{StudentID=6,CourseID=1045},
                new Enrollment{StudentID=7,CourseID=3141,Grade=Grade.A},
            };
            foreach (Enrollment e in enrollments)
            {

```

```
        context.Enrollments.Add(e);
    }
    context.SaveChanges();
}
}
```

The code checks if there are any students in the database, and if not, it assumes the database is new and needs to be seeded with test data. It loads test data into arrays rather than `List<T>` collections to optimize performance.

In `Program.cs`, modify the `Main` method to do the following on application startup:

- Get a database context instance from the dependency injection container.
  - Call the seed method, passing to it the context.
  - Dispose the context when the seed method is done.

```
public static void Main(string[] args)
{
    var host = BuildWebHost(args);

    using (var scope = host.Services.CreateScope())
    {
        var services = scope.ServiceProvider;
        try
        {
            var context = services.GetRequiredService<SchoolContext>();
            DbInitializer.Initialize(context);
        }
        catch (Exception ex)
        {
            var logger = services.GetRequiredService<ILogger<Program>>();
            logger.LogError(ex, "An error occurred while seeding the database.");
        }
    }

    host.Run();
}
```

Add `using` statements:

```
using Microsoft.Extensions.DependencyInjection;
using ContosoUniversity.Data;
```

In older tutorials, you may see similar code in the `Configure` method in `Startup.cs`. We recommend that you use the `Configure` method only to set up the request pipeline. Application startup code belongs in the `Main` method.

Now the first time you run the application, the database will be created and seeded with test data. Whenever you change your data model, you can delete the database, update your seed method, and start afresh with a new database the same way. In later tutorials, you'll see how to modify the database when the data model changes, without deleting and re-creating it.

## Create a controller and views

Next, you'll use the scaffolding engine in Visual Studio to add an MVC controller and views that will use EF to query and save data.

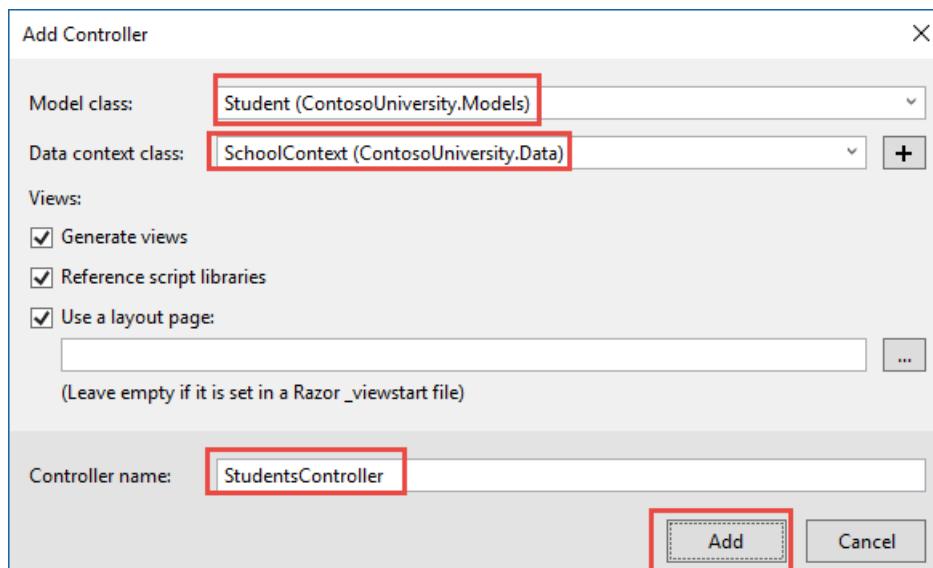

The automatic creation of CRUD action methods and views is known as scaffolding. Scaffolding differs from

code generation in that the scaffolded code is a starting point that you can modify to suit your own requirements, whereas you typically don't modify generated code. When you need to customize generated code, you use partial classes or you regenerate the code when things change.

- Right-click the **Controllers** folder in **Solution Explorer** and select **Add > New Scaffolded Item**.

If the **Add MVC Dependencies** dialog appears:

- [Update Visual Studio to the latest version](#). Visual Studio versions prior to 15.5 show this dialog.
- If you can't update, select **ADD**, and then follow the add controller steps again.
- In the **Add Scaffold** dialog box:
  - Select **MVC controller with views, using Entity Framework**.
  - Click **Add**.
- In the **Add Controller** dialog box:
  - In **Model class** select **Student**.
  - In **Data context class** select **SchoolContext**.
  - Accept the default **StudentsController** as the name.
  - Click **Add**.

When you click **Add**, the Visual Studio scaffolding engine creates a *StudentsController.cs* file and a set of views (*.cshtml* files) that work with the controller.

(The scaffolding engine can also create the database context for you if you don't create it manually first as you did earlier for this tutorial. You can specify a new context class in the **Add Controller** box by clicking the plus sign to the right of **Data context class**. Visual Studio will then create your `DbContext` class as well as the controller and views.)

You'll notice that the controller takes a `SchoolContext` as a constructor parameter.

```
namespace ContosoUniversity.Controllers
{
    public class StudentsController : Controller
    {
        private readonly SchoolContext _context;

        public StudentsController(SchoolContext context)
        {
            _context = context;
        }
    }
}
```

ASP.NET dependency injection will take care of passing an instance of `SchoolContext` into the controller. You configured that in the `Startup.cs` file earlier.

The controller contains an `Index` action method, which displays all students in the database. The method gets a list of students from the `Students` entity set by reading the `Students` property of the database context instance:

```
public async Task<IActionResult> Index()
{
    return View(await _context.Students.ToListAsync());
}
```

You'll learn about the asynchronous programming elements in this code later in the tutorial.

The `Views/Students/Index.cshtml` view displays this list in a table:

```

@model IEnumerable<ContosoUniversity.Models.Student>

 @{
     ViewData["Title"] = "Index";
 }

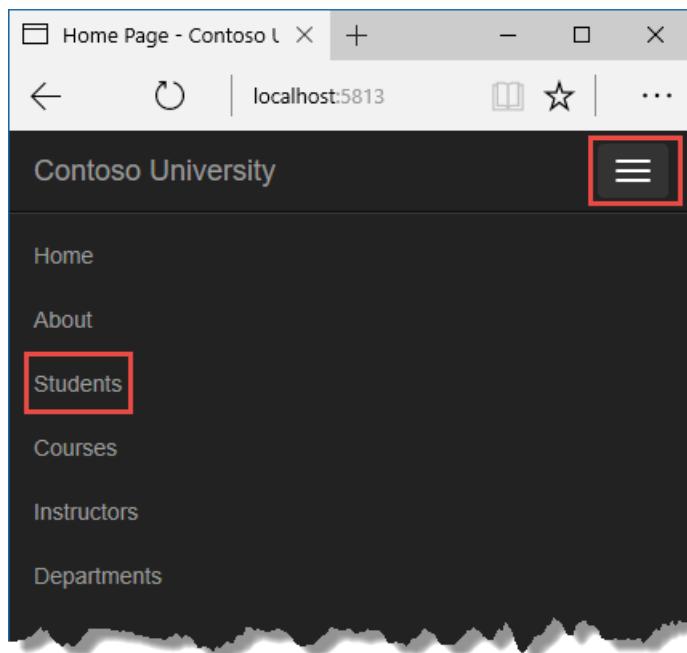

<h2>Index</h2>

<p>
    <a asp-action="Create">Create New</a>
</p>
<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.LastName)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.FirstMidName)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.EnrollmentDate)
            </th>
        <th></th>
    </tr>
    </thead>
    <tbody>
@foreach (var item in Model) {
    <tr>
        <td>
            @Html.DisplayFor(modelItem => item.LastName)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.FirstMidName)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.EnrollmentDate)
        </td>
        <td>
            <a asp-action="Edit" asp-route-id="@item.ID">Edit</a> |
            <a asp-action="Details" asp-route-id="@item.ID">Details</a> |
            <a asp-action="Delete" asp-route-id="@item.ID">Delete</a>
        </td>
    </tr>
}
    </tbody>
</table>

```

Press CTRL+F5 to run the project or choose **Debug > Start Without Debugging** from the menu.

Click the Students tab to see the test data that the `DbInitializer.Initialize` method inserted. Depending on how narrow your browser window is, you'll see the `Student` tab link at the top of the page or you'll have to click the navigation icon in the upper right corner to see the link.

Last Name	First Mid Name	Enrollment Date	Action
Alexander	Carson	9/1/2005 12:00:00 AM	Edit   Details   Delete
Alonso	Meredith	9/1/2002 12:00:00 AM	Edit   Details   Delete
Anand	Arturo	9/1/2003 12:00:00 AM	Edit   Details   Delete
Barzdukas	Gytis	9/1/2002 12:00:00 AM	Edit   Details   Delete

## View the Database

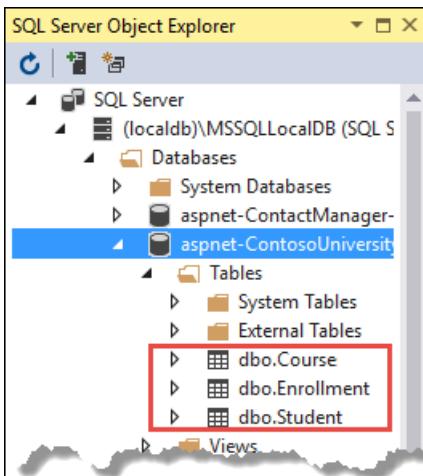

When you started the application, the `DbInitializer.Initialize` method calls `EnsureCreated`. EF saw that there was no database and so it created one, then the remainder of the `Initialize` method code populated the database with data. You can use **SQL Server Object Explorer** (SSOX) to view the database in Visual Studio.

Close the browser.

If the SSOX window isn't already open, select it from the **View** menu in Visual Studio.

In SSOX, click **(localdb)\MSSQLLocalDB > Databases**, and then click the entry for the database name that's in the connection string in your *appsettings.json* file.

Expand the **Tables** node to see the tables in your database.

Right-click the **Student** table and click **View Data** to see the columns that were created and the rows that were inserted into the table.

	ID	EnrollmentDate	FirstMidName	LastName
▶	1	9/1/2005 12:00:...	Carson	Alexander
	2	9/1/2002 12:00:...	Meredith	Alonso
	3	9/1/2003 12:00:...	Arturo	Anand
	4	9/1/2002 12:00:...	Gytis	Barzdukas
	5	9/1/2002 12:00:...	Yan	Li

The *.mdf* and *.ldf* database files are in the *C:\Users\* folder.

Because you're calling `EnsureCreated` in the initializer method that runs on app start, you could now make a change to the `Student` class, delete the database, run the application again, and the database would automatically be re-created to match your change. For example, if you add an `EmailAddress` property to the `Student` class, you'll see a new `EmailAddress` column in the re-created table.

## Conventions

The amount of code you had to write in order for the Entity Framework to be able to create a complete database for you is minimal because of the use of conventions, or assumptions that the Entity Framework makes.

- The names of `DbSet` properties are used as table names. For entities not referenced by a `Dbset` property, entity class names are used as table names.
- Entity property names are used for column names.
- Entity properties that are named `ID` or `classnameID` are recognized as primary key properties.
- A property is interpreted as a foreign key property if it's named (for example, `StudentID` for the `Student` navigation property since the `student` entity's primary key is `ID`). Foreign key properties can also be named simply (for example, `EnrollmentID` since the `Enrollment` entity's primary key is `EnrollmentID`).

Conventional behavior can be overridden. For example, you can explicitly specify table names, as you saw earlier in this tutorial. And you can set column names and set any property as primary key or foreign key, as you'll see in a [later tutorial](#) in this series.

## Asynchronous code

Asynchronous programming is the default mode for ASP.NET Core and EF Core.

A web server has a limited number of threads available, and in high load situations all of the available threads might be in use. When that happens, the server can't process new requests until the threads are freed up. With synchronous code, many threads may be tied up while they aren't actually doing any work because they're waiting for I/O to complete. With asynchronous code, when a process is waiting for I/O to complete, its thread is freed up for the server to use for processing other requests. As a result, asynchronous code enables server resources to be used more efficiently, and the server is enabled to handle more traffic without delays.

Asynchronous code does introduce a small amount of overhead at run time, but for low traffic situations the performance hit is negligible, while for high traffic situations, the potential performance improvement is substantial.

In the following code, the `async` keyword, `Task<T>` return value, `await` keyword, and `ToListAsync` method make the code execute asynchronously.

```
public async Task<IActionResult> Index()
{
    return View(await _context.Students.ToListAsync());
}
```

- The `async` keyword tells the compiler to generate callbacks for parts of the method body and to automatically create the `Task<IActionResult>` object that's returned.
- The return type `Task<IActionResult>` represents ongoing work with a result of type `IActionResult`.
- The `await` keyword causes the compiler to split the method into two parts. The first part ends with the operation that's started asynchronously. The second part is put into a callback method that's called when the operation completes.
- `ToListAsync` is the asynchronous version of the `ToList` extension method.

Some things to be aware of when you are writing asynchronous code that uses the Entity Framework:

- Only statements that cause queries or commands to be sent to the database are executed asynchronously. That includes, for example, `ToListAsync`, `SingleOrDefaultAsync`, and `SaveChangesAsync`. It doesn't include, for example, statements that just change an `IQueryable`, such as  
`var students = context.Students.Where(s => s.LastName == "Davolio")`.
- An EF context isn't thread safe: don't try to do multiple operations in parallel. When you call any async EF method, always use the `await` keyword.
- If you want to take advantage of the performance benefits of async code, make sure that any library packages that you're using (such as for paging), also use async if they call any Entity Framework methods that cause queries to be sent to the database.

For more information about asynchronous programming in .NET, see [Async Overview](#).

## Summary

You've now created a simple application that uses the Entity Framework Core and SQL Server Express LocalDB to store and display data. In the following tutorial, you'll learn how to perform basic CRUD (create, read, update, delete) operations.

# ASP.NET Core MVC with EF Core - CRUD - 2 of 10

6/28/2018 • 20 minutes to read • [Edit Online](#)

This tutorial has not been upgraded to ASP.NET Core 2.1. The ASP.NET Core 2.0 version of this tutorial is available by selecting **ASP.NET Core 2.0** above the table of contents or at the top of the page:

The ASP.NET Core 2.1 Razor Pages version of this tutorial has many improvements over the 2.0 version.

The 2.0 tutorial teaches ASP.NET Core MVC and Entity Framework Core with controllers and views. Razor Pages is a page-based programming model that makes building web UI easier and more productive. We recommend the [Razor Pages](#) tutorial over the MVC version. The Razor Pages tutorial:

- Is easier to follow. For example, the scaffolding code has been significantly simplified.
- Provides more EF Core best practices.
- Uses more efficient queries.
- Is more current with the latest API.
- Covers more features.
- Is the preferred approach for new application development.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub discussion](#).

By [Tom Dykstra](#) and [Rick Anderson](#)

The Contoso University sample web application demonstrates how to create ASP.NET Core MVC web applications using Entity Framework Core and Visual Studio. For information about the tutorial series, see [the first tutorial in the series](#).

In the previous tutorial, you created an MVC application that stores and displays data using the Entity Framework and SQL Server LocalDB. In this tutorial, you'll review and customize the CRUD (create, read, update, delete) code that the MVC scaffolding automatically creates for you in controllers and views.

## NOTE

It's a common practice to implement the repository pattern in order to create an abstraction layer between your controller and the data access layer. To keep these tutorials simple and focused on teaching how to use the Entity Framework itself, they don't use repositories. For information about repositories with EF, see [the last tutorial in this series](#).

In this tutorial, you'll work with the following web pages:

Details - Contoso Univ × +

localhost:5813/Students/Details/1

Contoso University Home About Students Courses Instructors Departments Register Log in

## Student

Last Name	Alexander	
First/Middle Name	Carson	
Enrollment Date	9/1/2005 12:00:00 AM

## Create

### Student

Last Name

First/Middle Name

Enrollment Date

Create

A screenshot of a web browser window titled "Edit - c" showing the "Edit" view for a student. The URL is "localhost". The page has a header "Contoso University" and a navigation menu icon. The main content area is titled "Edit" and "Student". It contains three text input fields: "LastName" (value: Alexander), "FirstMidName" (value: Carson), and "EnrollmentDate" (value: 2005-09-01T00:00:00.000). Below the inputs is a "Save" button.

A screenshot of a web browser window titled "Delete" showing the "Delete" view for a student. The URL is "localhost". The page has a header "Contoso University" and a navigation menu icon. The main content area is titled "Delete" and "Student". It displays the student's details: "LastName" (Alexander), "FirstMidName" (Carson), and "EnrollmentDate" (9/2/2005 12:00:00 AM). At the bottom are two buttons: "Delete" and "Back to List".

## Customize the Details page

The scaffolded code for the Students Index page left out the `Enrollments` property, because that property holds a collection. In the **Details** page, you'll display the contents of the collection in an HTML table.

In `Controllers/StudentsController.cs`, the action method for the Details view uses the `SingleOrDefaultAsync` method to retrieve a single `Student` entity. Add code that calls `Include`, `ThenInclude`, and `AsNoTracking`.

methods, as shown in the following highlighted code.

```
public async Task<IActionResult> Details(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var student = await _context.Students
        .Include(s => s.Enrollments)
        .ThenInclude(e => e.Course)
        .AsNoTracking()
        .SingleOrDefaultAsync(m => m.ID == id);

    if (student == null)
    {
        return NotFound();
    }

    return View(student);
}
```

The `Include` and `ThenInclude` methods cause the context to load the `Student.Enrollments` navigation property, and within each enrollment the `Enrollment.Course` navigation property. You'll learn more about these methods in the [read related data](#) tutorial.

The `AsNoTracking` method improves performance in scenarios where the entities returned won't be updated in the current context's lifetime. You'll learn more about `AsNoTracking` at the end of this tutorial.

## Route data

The key value that's passed to the `Details` method comes from *route data*. Route data is data that the model binder found in a segment of the URL. For example, the default route specifies controller, action, and id segments:

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

In the following URL, the default route maps Instructor as the controller, Index as the action, and 1 as the id; these are route data values.

```
http://localhost:1230/Instructor/Index/1?courseID=2021
```

The last part of the URL ("?courseID=2021") is a query string value. The model binder will also pass the ID value to the `Details` method `id` parameter if you pass it as a query string value:

```
http://localhost:1230/Instructor/Index?id=1&CourseID=2021
```

In the Index page, hyperlink URLs are created by tag helper statements in the Razor view. In the following Razor code, the `id` parameter matches the default route, so `id` is added to the route data.

```
<a asp-action="Edit" asp-route-id="@item.ID">Edit</a>
```

This generates the following HTML when `item.ID` is 6:

```
<a href="/Students/Edit/6">Edit</a>
```

In the following Razor code, `studentID` doesn't match a parameter in the default route, so it's added as a query string.

```
<a asp-action="Edit" asp-route-studentID="@item.ID">Edit</a>
```

This generates the following HTML when `item.ID` is 6:

```
<a href="/Students/Edit?studentID=6">Edit</a>
```

For more information about tag helpers, see [Tag helpers in ASP.NET Core](#).

### Add enrollments to the Details view

Open `Views/Students/Details.cshtml`. Each field is displayed using `DisplayNameFor` and `DisplayFor` helpers, as shown in the following example:

```
<dt>
    @Html.DisplayNameFor(model => model.LastName)
</dt>
<dd>
    @Html.DisplayFor(model => model.LastName)
</dd>
```

After the last field and immediately before the closing `</dl>` tag, add the following code to display a list of enrollments:

```
<dt>
    @Html.DisplayNameFor(model => model.Enrollments)
</dt>
<dd>
    <table class="table">
        <tr>
            <th>Course Title</th>
            <th>Grade</th>
        </tr>
        @foreach (var item in Model.Enrollments)
        {
            <tr>
                <td>
                    @Html.DisplayFor(modelItem => item.Course.Title)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Grade)
                </td>
            </tr>
        }
    </table>
</dd>
```

If code indentation is wrong after you paste the code, press CTRL-K-D to correct it.

This code loops through the entities in the `Enrollments` navigation property. For each enrollment, it displays the course title and the grade. The course title is retrieved from the `Course` entity that's stored in the `Course` navigation property of the `Enrollments` entity.

Run the app, select the **Students** tab, and click the **Details** link for a student. You see the list of courses and grades for the selected student:

The screenshot shows a browser window titled "Details - Contoso Unive". The address bar displays "localhost:5813/Students/Details/1". The page header for "Contoso University" includes links for Home, About, Students, Courses, Instructors, Departments, Register, and Log in. The main content area is titled "Student". It shows a table with student information and enrollment details.

Last Name	Alexander
First/Middle Name	Carson
Enrollment Date	9/1/2005 12:00:00 AM
Enrollments	
Course Title	Grade
Chemistry	A
Microeconomics	C
Macroeconomics	B

## Update the Create page

In *StudentsController.cs*, modify the `HttpPost [Create]` method by adding a try-catch block and removing ID from the `Bind` attribute.

```
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Create(
    [Bind("EnrollmentDate,FirstMidName,LastName")] Student student)
{
    try
    {
        if (ModelState.IsValid)
        {
            _context.Add(student);
            await _context.SaveChangesAsync();
            return RedirectToAction(nameof(Index));
        }
    }
    catch (DbUpdateException /* ex */)
    {
        //Log the error (uncomment ex variable name and write a log.
        ModelState.AddModelError("", "Unable to save changes. " +
            "Try again, and if the problem persists " +
            "see your system administrator.");
    }
    return View(student);
}
```

This code adds the Student entity created by the ASP.NET MVC model binder to the Students entity set and then saves the changes to the database. (Model binder refers to the ASP.NET MVC functionality that makes it easier for you to work with data submitted by a form; a model binder converts posted form values to CLR types and

passes them to the action method in parameters. In this case, the model binder instantiates a Student entity for you using property values from the Form collection.)

You removed `ID` from the `Bind` attribute because ID is the primary key value which SQL Server will set automatically when the row is inserted. Input from the user doesn't set the ID value.

Other than the `Bind` attribute, the try-catch block is the only change you've made to the scaffolded code. If an exception that derives from `DbUpdateException` is caught while the changes are being saved, a generic error message is displayed. `DbUpdateException` exceptions are sometimes caused by something external to the application rather than a programming error, so the user is advised to try again. Although not implemented in this sample, a production quality application would log the exception. For more information, see the **Log for insight** section in [Monitoring and Telemetry \(Building Real-World Cloud Apps with Azure\)](#).

The `ValidateAntiForgeryToken` attribute helps prevent cross-site request forgery (CSRF) attacks. The token is automatically injected into the view by the [FormTagHelper](#) and is included when the form is submitted by the user. The token is validated by the `ValidateAntiForgeryToken` attribute. For more information about CSRF, see [Anti-Request Forgery](#).

### Security note about overposting

The `Bind` attribute that the scaffolded code includes on the `Create` method is one way to protect against overposting in create scenarios. For example, suppose the Student entity includes a `Secret` property that you don't want this web page to set.

```
public class Student
{
    public int ID { get; set; }
    public string LastName { get; set; }
    public string FirstMidName { get; set; }
    public DateTime EnrollmentDate { get; set; }
    public string Secret { get; set; }
}
```

Even if you don't have a `Secret` field on the web page, a hacker could use a tool such as Fiddler, or write some JavaScript, to post a `Secret` form value. Without the `Bind` attribute limiting the fields that the model binder uses when it creates a Student instance, the model binder would pick up that `Secret` form value and use it to create the Student entity instance. Then whatever value the hacker specified for the `Secret` form field would be updated in your database. The following image shows the Fiddler tool adding the `Secret` field (with the value "OverPost") to the posted form values.

The screenshot shows the Fiddler web debugger interface. At the top, there are tabs for Statistics, Inspectors, AutoResponder, Composer, Filters, Log, and Timeline. Below the tabs, a message says "Use this page to compose a Request. You can clone a prior request by dragging and dropping a session from the Web Sessions list." On the right side of the interface, there is a large red box around the "Execute" button. The main area shows a "Parsed" tab selected, with "Raw", "Scratchpad", and "Options" tabs below it. The "Raw" tab displays a POST request to "http://localhost:1236/Student/Create" over "HTTP/1.1". The "Request Headers" section includes fields like Host, User-Agent, Accept, Accept-Language, Accept-Encoding, Referer, Cookie, Connection, Content-Type, and Content-Length. The "Request Body" section shows the URL-encoded data: "s1&LastName=Smith&FirstName=Joe&EnrollmentDate=7%2F31%2F2013+4%3A58%3A23+PM&Secret=OverPost". A red box highlights the "Secret" parameter.

The value "OverPost" would then be successfully added to the `Secret` property of the inserted row, although you never intended that the web page be able to set that property.

You can prevent overposting in edit scenarios by reading the entity from the database first and then calling `TryUpdateModel`, passing in an explicit allowed properties list. That's the method used in these tutorials.

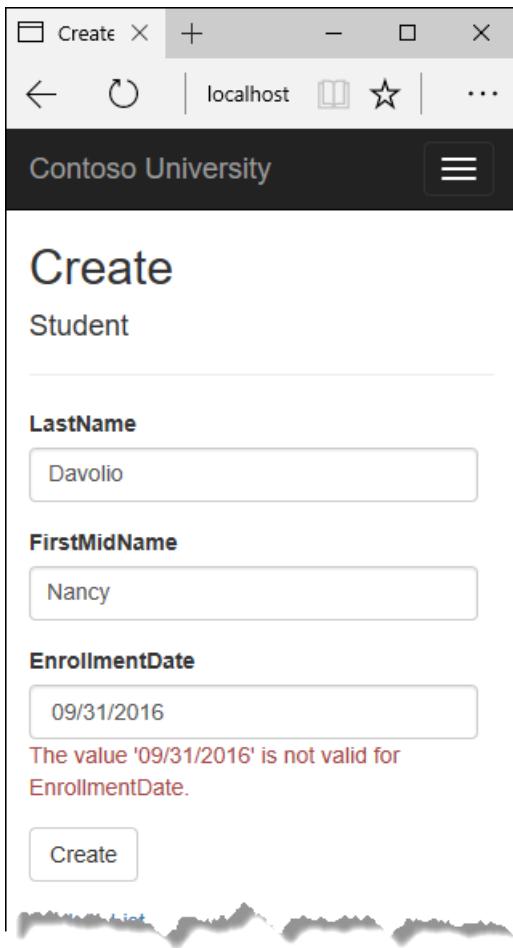

An alternative way to prevent overposting that's preferred by many developers is to use view models rather than entity classes with model binding. Include only the properties you want to update in the view model. Once the MVC model binder has finished, copy the view model properties to the entity instance, optionally using a tool such as AutoMapper. Use `_context.Entry` on the entity instance to set its state to `Unchanged`, and then set `Property("PropertyName").IsModified` to true on each entity property that's included in the view model. This method works in both edit and create scenarios.

### Test the Create page

The code in `Views/Students/Create.cshtml` uses `label`, `input`, and `span` (for validation messages) tag helpers for each field.

Run the app, select the **Students** tab, and click **Create New**.

Enter names and a date. Try entering an invalid date if your browser lets you do that. (Some browsers force you to use a date picker.) Then click **Create** to see the error message.

This is server-side validation that you get by default; in a later tutorial you'll see how to add attributes that will generate code for client-side validation also. The following highlighted code shows the model validation check in the `Create` method.

```
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Create(
    [Bind("EnrollmentDate,FirstMidName,LastName")] Student student)
{
    try
    {
        if (ModelState.IsValid)
        {
            _context.Add(student);
            await _context.SaveChangesAsync();
            return RedirectToAction(nameof(Index));
        }
    }
    catch (DbUpdateException /* ex */)
    {
        //Log the error (uncomment ex variable name and write a log.
        ModelState.AddModelError("", "Unable to save changes. " +
            "Try again, and if the problem persists " +
            "see your system administrator.");
    }
    return View(student);
}
```

Change the date to a valid value and click **Create** to see the new student appear in the **Index** page.

## Update the Edit page

In `StudentController.cs`, the `HttpGet` `Edit` method (the one without the `HttpPost` attribute) uses the

`SingleOrDefaultAsync` method to retrieve the selected Student entity, as you saw in the `Details` method. You don't need to change this method.

## Recommended `HttpPost Edit` code: Read and update

Replace the `HttpPost Edit` action method with the following code.

```
[HttpPost, ActionName("Edit")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> EditPost(int? id)
{
    if (id == null)
    {
        return NotFound();
    }
    var studentToUpdate = await _context.Students.SingleOrDefault(s => s.ID == id);
    if (await TryUpdateModelAsync<Student>(
        studentToUpdate,
        "",
        s => s.FirstMidName, s => s.LastName, s => s.EnrollmentDate))
    {
        try
        {
            await _context.SaveChangesAsync();
            return RedirectToAction(nameof(Index));
        }
        catch (DbUpdateException /* ex */)
        {
            //Log the error (uncomment ex variable name and write a log.)
            ModelState.AddModelError("", "Unable to save changes. " +
                "Try again, and if the problem persists, " +
                "see your system administrator.");
        }
    }
    return View(studentToUpdate);
}
```

These changes implement a security best practice to prevent overposting. The scaffolder generated a `Bind` attribute and added the entity created by the model binder to the entity set with a `Modified` flag. That code isn't recommended for many scenarios because the `Bind` attribute clears out any pre-existing data in fields not listed in the `Include` parameter.

The new code reads the existing entity and calls `TryUpdateModel` to update fields in the retrieved entity [based on user input in the posted form data](#). The Entity Framework's automatic change tracking sets the `Modified` flag on the fields that are changed by form input. When the `SaveChanges` method is called, the Entity Framework creates SQL statements to update the database row. Concurrency conflicts are ignored, and only the table columns that were updated by the user are updated in the database. (A later tutorial shows how to handle concurrency conflicts.)

As a best practice to prevent overposting, the fields that you want to be updateable by the `Edit` page are whitelisted in the `TryUpdateModel` parameters. (The empty string preceding the list of fields in the parameter list is for a prefix to use with the form fields names.) Currently there are no extra fields that you're protecting, but listing the fields that you want the model binder to bind ensures that if you add fields to the data model in the future, they're automatically protected until you explicitly add them here.

As a result of these changes, the method signature of the `HttpPost Edit` method is the same as the `HttpGet Edit` method; therefore you've renamed the method `EditPost`.

## Alternative `HttpPost Edit` code: Create and attach

The recommended `HttpPost edit` code ensures that only changed columns get updated and preserves data in properties that you don't want included for model binding. However, the read-first approach requires an extra

database read, and can result in more complex code for handling concurrency conflicts. An alternative is to attach an entity created by the model binder to the EF context and mark it as modified. (Don't update your project with this code, it's only shown to illustrate an optional approach.)

```
public async Task<IActionResult> Edit(int id, [Bind("ID,EnrollmentDate,FirstMidName,LastName")] Student student)
{
    if (id != student.ID)
    {
        return NotFound();
    }
    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(student);
            await _context.SaveChangesAsync();
            return RedirectToAction(nameof(Index));
        }
        catch (DbUpdateException /* ex */)
        {
            //Log the error (uncomment ex variable name and write a log.)
            ModelState.AddModelError("", "Unable to save changes. " +
                "Try again, and if the problem persists, " +
                "see your system administrator.");
        }
    }
    return View(student);
}
```

You can use this approach when the web page UI includes all of the fields in the entity and can update any of them.

The scaffolded code uses the create-and-attach approach but only catches `DbUpdateConcurrencyException` exceptions and returns 404 error codes. The example shown catches any database update exception and displays an error message.

## Entity States

The database context keeps track of whether entities in memory are in sync with their corresponding rows in the database, and this information determines what happens when you call the `SaveChanges` method. For example, when you pass a new entity to the `Add` method, that entity's state is set to `Added`. Then when you call the `SaveChanges` method, the database context issues a SQL INSERT command.

An entity may be in one of the following states:

- `Added`. The entity doesn't yet exist in the database. The `SaveChanges` method issues an INSERT statement.
- `Unchanged`. Nothing needs to be done with this entity by the `SaveChanges` method. When you read an entity from the database, the entity starts out with this status.
- `Modified`. Some or all of the entity's property values have been modified. The `SaveChanges` method issues an UPDATE statement.
- `Deleted`. The entity has been marked for deletion. The `SaveChanges` method issues a DELETE statement.
- `Detached`. The entity isn't being tracked by the database context.

In a desktop application, state changes are typically set automatically. You read an entity and make changes to some of its property values. This causes its entity state to automatically be changed to `Modified`. Then when you call `SaveChanges`, the Entity Framework generates a SQL UPDATE statement that updates only the actual properties that you changed.

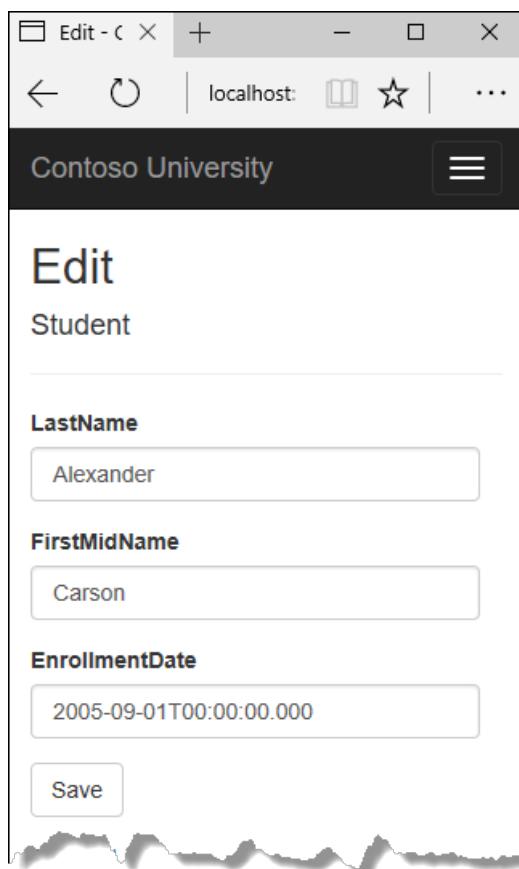

In a web app, the `DbContext` that initially reads an entity and displays its data to be edited is disposed after a page is rendered. When the `HttpPost Edit` action method is called, a new web request is made and you have a new instance of the `DbContext`. If you re-read the entity in that new context, you simulate desktop processing.

But if you don't want to do the extra read operation, you have to use the entity object created by the model binder. The simplest way to do this is to set the entity state to Modified as is done in the alternative `HttpPost Edit` code shown earlier. Then when you call `SaveChanges`, the Entity Framework updates all columns of the database row, because the context has no way to know which properties you changed.

If you want to avoid the read-first approach, but you also want the SQL UPDATE statement to update only the fields that the user actually changed, the code is more complex. You have to save the original values in some way (such as by using hidden fields) so that they're available when the `HttpPost Edit` method is called. Then you can create a Student entity using the original values, call the `Attach` method with that original version of the entity, update the entity's values to the new values, and then call `SaveChanges`.

## Test the Edit page

Run the app, select the **Students** tab, then click an **Edit** hyperlink.

Change some of the data and click **Save**. The **Index** page opens and you see the changed data.

## Update the Delete page

In `StudentController.cs`, the template code for the `HttpGet Delete` method uses the `SingleOrDefaultAsync` method to retrieve the selected Student entity, as you saw in the Details and Edit methods. However, to implement a custom error message when the call to `SaveChanges` fails, you'll add some functionality to this method and its corresponding view.

As you saw for update and create operations, delete operations require two action methods. The method that's called in response to a GET request displays a view that gives the user a chance to approve or cancel the delete operation. If the user approves it, a POST request is created. When that happens, the `HttpPost Delete` method is called and then that method actually performs the delete operation.

You'll add a try-catch block to the `HttpPost Delete` method to handle any errors that might occur when the database is updated. If an error occurs, the `HttpPost Delete` method calls the `HttpGet Delete` method, passing it a parameter that indicates that an error has occurred. The `HttpGet Delete` method then redisplays the confirmation page along with the error message, giving the user an opportunity to cancel or try again.

Replace the `HttpGet Delete` action method with the following code, which manages error reporting.

```
public async Task<IActionResult> Delete(int? id, bool? saveChangesError = false)
{
    if (id == null)
    {
        return NotFound();
    }

    var student = await _context.Students
        .AsNoTracking()
        .SingleOrDefaultAsync(m => m.ID == id);
    if (student == null)
    {
        return NotFound();
    }

    if (saveChangesError.GetValueOrDefault())
    {
        ViewData["ErrorMessage"] =
            "Delete failed. Try again, and if the problem persists " +
            "see your system administrator.";
    }

    return View(student);
}
```

This code accepts an optional parameter that indicates whether the method was called after a failure to save changes. This parameter is `false` when the `HttpGet Delete` method is called without a previous failure. When it's called by the `HttpPost Delete` method in response to a database update error, the parameter is `true` and an error message is passed to the view.

### The read-first approach to `HttpPost Delete`

Replace the `HttpPost Delete` action method (named `DeleteConfirmed`) with the following code, which performs the actual delete operation and catches any database update errors.

```

[HttpPost, ActionName("Delete")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> DeleteConfirmed(int id)
{
    var student = await _context.Students
        .AsNoTracking()
        .SingleOrDefaultAsync(m => m.ID == id);
    if (student == null)
    {
        return RedirectToAction(nameof(Index));
    }

    try
    {
        _context.Students.Remove(student);
        await _context.SaveChangesAsync();
        return RedirectToAction(nameof(Index));
    }
    catch (DbUpdateException /* ex */)
    {
        //Log the error (uncomment ex variable name and write a log.)
        return RedirectToAction(nameof(Delete), new { id = id, saveChangesError = true });
    }
}

```

This code retrieves the selected entity, then calls the `Remove` method to set the entity's status to `Deleted`. When `SaveChanges` is called, a SQL DELETE command is generated.

### The create-and-attach approach to `HttpPost Delete`

If improving performance in a high-volume application is a priority, you could avoid an unnecessary SQL query by instantiating a Student entity using only the primary key value and then setting the entity state to `Deleted`. That's all that the Entity Framework needs in order to delete the entity. (Don't put this code in your project; it's here just to illustrate an alternative.)

```

[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> DeleteConfirmed(int id)
{
    try
    {
        Student studentToDelete = new Student() { ID = id };
        _context.Entry(studentToDelete).State = EntityState.Deleted;
        await _context.SaveChangesAsync();
        return RedirectToAction(nameof(Index));
    }
    catch (DbUpdateException /* ex */)
    {
        //Log the error (uncomment ex variable name and write a log.)
        return RedirectToAction(nameof(Delete), new { id = id, saveChangesError = true });
    }
}

```

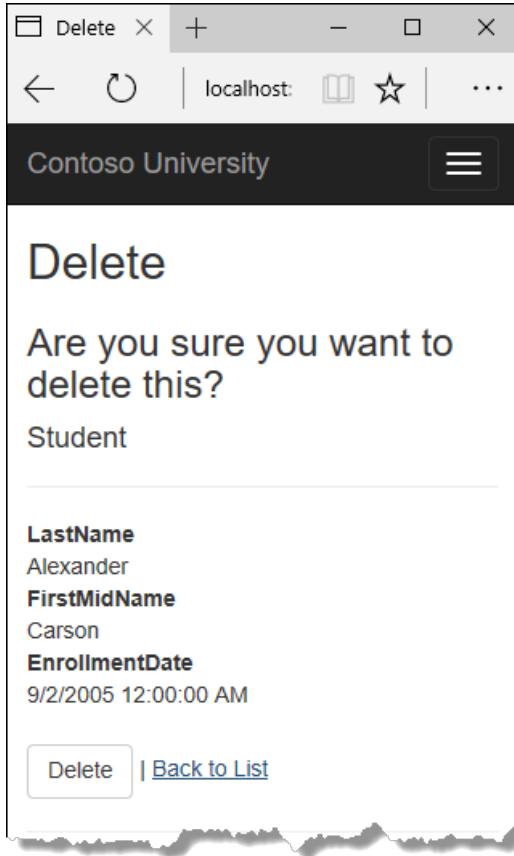

If the entity has related data that should also be deleted, make sure that cascade delete is configured in the database. With this approach to entity deletion, EF might not realize there are related entities to be deleted.

### Update the Delete view

In `Views/Student/Delete.cshtml`, add an error message between the h2 heading and the h3 heading, as shown in the following example:

```
<h2>Delete</h2>
<p class="text-danger">@ViewData["ErrorMessage"]</p>
<h3>Are you sure you want to delete this?</h3>
```

Run the app, select the **Students** tab, and click a **Delete** hyperlink:

Click **Delete**. The Index page is displayed without the deleted student. (You'll see an example of the error handling code in action in the concurrency tutorial.)

## Closing database connections

To free up the resources that a database connection holds, the context instance must be disposed as soon as possible when you are done with it. The ASP.NET Core built-in [dependency injection](#) takes care of that task for you.

In *Startup.cs*, you call the [AddDbContext extension method](#) to provision the `DbContext` class in the ASP.NET DI container. That method sets the service lifetime to `Scoped` by default. `Scoped` means the context object lifetime coincides with the web request life time, and the `Dispose` method will be called automatically at the end of the web request.

## Handling Transactions

By default the Entity Framework implicitly implements transactions. In scenarios where you make changes to multiple rows or tables and then call `SaveChanges`, the Entity Framework automatically makes sure that either all of your changes succeed or they all fail. If some changes are done first and then an error happens, those changes are automatically rolled back. For scenarios where you need more control -- for example, if you want to include operations done outside of Entity Framework in a transaction -- see [Transactions](#).

## No-tracking queries

When a database context retrieves table rows and creates entity objects that represent them, by default it keeps

track of whether the entities in memory are in sync with what's in the database. The data in memory acts as a cache and is used when you update an entity. This caching is often unnecessary in a web application because context instances are typically short-lived (a new one is created and disposed for each request) and the context that reads an entity is typically disposed before that entity is used again.

You can disable tracking of entity objects in memory by calling the `AsNoTracking` method. Typical scenarios in which you might want to do that include the following:

- During the context lifetime you don't need to update any entities, and you don't need EF to automatically load navigation properties with entities retrieved by separate queries. Frequently these conditions are met in a controller's `HttpGet` action methods.
- You are running a query that retrieves a large volume of data, and only a small portion of the returned data will be updated. It may be more efficient to turn off tracking for the large query, and run a query later for the few entities that need to be updated.
- You want to attach an entity in order to update it, but earlier you retrieved the same entity for a different purpose. Because the entity is already being tracked by the database context, you can't attach the entity that you want to change. One way to handle this situation is to call `AsNoTracking` on the earlier query.

For more information, see [Tracking vs. No-Tracking](#).

## Summary

You now have a complete set of pages that perform simple CRUD operations for Student entities. In the next tutorial you'll expand the functionality of the **Index** page by adding sorting, filtering, and paging.

[PREVIOUS](#)

[NEXT](#)

# ASP.NET Core MVC with EF Core - Sort, Filter, Paging - 3 of 10

6/28/2018 • 15 minutes to read • [Edit Online](#)

This tutorial has not been upgraded to ASP.NET Core 2.1. The ASP.NET Core 2.0 version of this tutorial is available by selecting **ASP.NET Core 2.0** above the table of contents or at the top of the page:

The ASP.NET Core 2.1 Razor Pages version of this tutorial has many improvements over the 2.0 version.

The 2.0 tutorial teaches ASP.NET Core MVC and Entity Framework Core with controllers and views. Razor Pages is a page-based programming model that makes building web UI easier and more productive. We recommend the [Razor Pages](#) tutorial over the MVC version. The Razor Pages tutorial:

- Is easier to follow. For example, the scaffolding code has been significantly simplified.
- Provides more EF Core best practices.
- Uses more efficient queries.
- Is more current with the latest API.
- Covers more features.
- Is the preferred approach for new application development.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub discussion](#).

By [Tom Dykstra](#) and [Rick Anderson](#)

The Contoso University sample web application demonstrates how to create ASP.NET Core MVC web applications using Entity Framework Core and Visual Studio. For information about the tutorial series, see [the first tutorial in the series](#).

In the previous tutorial, you implemented a set of web pages for basic CRUD operations for Student entities. In this tutorial you'll add sorting, filtering, and paging functionality to the Students Index page. You'll also create a page that does simple grouping.

The following illustration shows what the page will look like when you're done. The column headings are links that the user can click to sort by that column. Clicking a column heading repeatedly toggles between ascending and descending sort order.

The screenshot shows a browser window with the title "Index - Contoso University". The address bar says "localhost:5813/Student". The main content is titled "Contoso University" with a three-line menu icon. Below it is the word "Index". A "Create New" link is visible. A search bar with placeholder "Find by name:" and a "Search" button is present. Below the search is a table header with columns "Last Name", "First Name", and "Enrollment Date". Three student records are listed:

Last Name	First Name	Enrollment Date	
Alexander	Carson	9/1/2005 12:00:00 AM	Edit   Details   Delete
Alonso	Meredith	9/1/2002 12:00:00 AM	Edit   Details   Delete
Anand	Arturo	9/1/2003 12:00:00 AM	Edit   Details   Delete

At the bottom are "Previous" and "Next" navigation buttons.

## Add Column Sort Links to the Students Index Page

To add sorting to the Student Index page, you'll change the `Index` method of the Students controller and add code to the Student Index view.

### Add sorting Functionality to the Index method

In `StudentsController.cs`, replace the `Index` method with the following code:

```
public async Task<IActionResult> Index(string sortOrder)
{
    ViewData["NameSortParm"] = String.IsNullOrEmpty(sortOrder) ? "name_desc" : "";
    ViewData["DateSortParm"] = sortOrder == "Date" ? "date_desc" : "Date";
    var students = from s in _context.Students
                  select s;
    switch (sortOrder)
    {
        case "name_desc":
            students = students.OrderByDescending(s => s.LastName);
            break;
        case "Date":
            students = students.OrderBy(s => s.EnrollmentDate);
            break;
        case "date_desc":
            students = students.OrderByDescending(s => s.EnrollmentDate);
            break;
        default:
            students = students.OrderBy(s => s.LastName);
            break;
    }
    return View(await students.AsNoTracking().ToListAsync());
}
```

This code receives a `sortOrder` parameter from the query string in the URL. The query string value is provided by ASP.NET Core MVC as a parameter to the action method. The parameter will be a string that's either "Name" or "Date", optionally followed by an underscore and the string "desc" to specify descending order. The default sort order is ascending.

The first time the Index page is requested, there's no query string. The students are displayed in ascending order by last name, which is the default as established by the fall-through case in the `switch` statement. When the user clicks a column heading hyperlink, the appropriate `sortOrder` value is provided in the query string.

The two `ViewData` elements (`NameSortParm` and `DateSortParm`) are used by the view to configure the column heading hyperlinks with the appropriate query string values.

```
public async Task<IActionResult> Index(string sortOrder)
{
    ViewData["NameSortParm"] = String.IsNullOrEmpty(sortOrder) ? "name_desc" : "";
    ViewData["DateSortParm"] = sortOrder == "Date" ? "date_desc" : "Date";
    var students = from s in _context.Students
                  select s;
    switch (sortOrder)
    {
        case "name_desc":
            students = students.OrderByDescending(s => s.LastName);
            break;
        case "Date":
            students = students.OrderBy(s => s.EnrollmentDate);
            break;
        case "date_desc":
            students = students.OrderByDescending(s => s.EnrollmentDate);
            break;
        default:
            students = students.OrderBy(s => s.LastName);
            break;
    }
    return View(await students.AsNoTracking().ToListAsync());
}
```

These are ternary statements. The first one specifies that if the `sortOrder` parameter is null or empty, `NameSortParm` should be set to "name\_desc"; otherwise, it should be set to an empty string. These two statements enable the view to set the column heading hyperlinks as follows:

CURRENT SORT ORDER	LAST NAME HYPERLINK	DATE HYPERLINK
Last Name ascending	descending	ascending
Last Name descending	ascending	ascending
Date ascending	ascending	descending
Date descending	ascending	ascending

The method uses LINQ to Entities to specify the column to sort by. The code creates an `IQueryable` variable before the `switch` statement, modifies it in the `switch` statement, and calls the `ToToListAsync` method after the `switch` statement. When you create and modify `IQueryable` variables, no query is sent to the database. The query isn't executed until you convert the `IQueryable` object into a collection by calling a method such as `ToToListAsync`. Therefore, this code results in a single query that's not executed until the `return View` statement.

This code could get verbose with a large number of columns. [The last tutorial in this series](#) shows how to write code that lets you pass the name of the `OrderBy` column in a string variable.

### Add column heading hyperlinks to the Student Index view

Replace the code in `Views/Students/Index.cshtml`, with the following code to add column heading hyperlinks. The changed lines are highlighted.

```

@model IEnumerable<ContosoUniversity.Models.Student>

 @{
     ViewData["Title"] = "Index";
 }

<h2>Index</h2>

<p>
    <a asp-action="Create">Create New</a>
</p>
<table class="table">
    <thead>
        <tr>
            <th>
                <a asp-action="Index" asp-route-
sortOrder="@ViewData["NameSortParm"]">@Html.DisplayNameFor(model => model.LastName)</a>
            </th>
            <th>
                @Html.DisplayNameFor(model => model.FirstMidName)
            </th>
            <th>
                <a asp-action="Index" asp-route-
sortOrder="@ViewData["DateSortParm"]">@Html.DisplayNameFor(model => model.EnrollmentDate)</a>
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
@foreach (var item in Model) {
        <tr>
            <td>
                @Html.DisplayFor(modelItem => item.LastName)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.FirstMidName)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.EnrollmentDate)
            </td>
            <td>
                <a asp-action="Edit" asp-route-id="@item.ID">Edit</a> |
                <a asp-action="Details" asp-route-id="@item.ID">Details</a> |
                <a asp-action="Delete" asp-route-id="@item.ID">Delete</a>
            </td>
        </tr>
}
    </tbody>
</table>

```

This code uses the information in `ViewData` properties to set up hyperlinks with the appropriate query string values.

Run the app, select the **Students** tab, and click the **Last Name** and **Enrollment Date** column headings to verify that sorting works.

Last Name	First Mid Name	Enrollment Date	
Alexander	Carson	9/2/2005 12:00:00 AM	Edit   Details   Delete
Alonso	Meredith	9/1/2002 12:00:00 AM	Edit   Details   Delete
Anand	Arturo	9/1/2003 12:00:00 AM	Edit   Details   Delete
Barzdukas	Gytis	9/1/2002 12:00:00 AM	Edit   Details   Delete

## Add a Search Box to the Students Index page

To add filtering to the Students Index page, you'll add a text box and a submit button to the view and make corresponding changes in the `Index` method. The text box will let you enter a string to search for in the first name and last name fields.

### Add filtering functionality to the Index method

In `StudentsController.cs`, replace the `Index` method with the following code (the changes are highlighted).

```
public async Task<IActionResult> Index(string sortOrder, string searchString)
{
    ViewData["NameSortParm"] = String.IsNullOrEmpty(sortOrder) ? "name_desc" : "";
    ViewData["DateSortParm"] = sortOrder == "Date" ? "date_desc" : "Date";
    ViewData["CurrentFilter"] = searchString;

    var students = from s in _context.Students
                  select s;
    if (!String.IsNullOrEmpty(searchString))
    {
        students = students.Where(s => s.LastName.Contains(searchString)
                           || s.FirstMidName.Contains(searchString));
    }
    switch (sortOrder)
    {
        case "name_desc":
            students = students.OrderByDescending(s => s.LastName);
            break;
        case "Date":
            students = students.OrderBy(s => s.EnrollmentDate);
            break;
        case "date_desc":
            students = students.OrderByDescending(s => s.EnrollmentDate);
            break;
        default:
            students = students.OrderBy(s => s.LastName);
            break;
    }
    return View(await students.AsNoTracking().ToListAsync());
}
```

You've added a `searchString` parameter to the `Index` method. The search string value is received from a text box that you'll add to the Index view. You've also added to the LINQ statement a where clause that selects only students whose first name or last name contains the search string. The statement that adds the where clause is executed only if there's a value to search for.

#### NOTE

Here you are calling the `Where` method on an `IQueryable` object, and the filter will be processed on the server. In some scenarios you might be calling the `Where` method as an extension method on an in-memory collection. (For example, suppose you change the reference to `_context.Students` so that instead of an EF `DbSet` it references a repository method that returns an `IEnumerable` collection.) The result would normally be the same but in some cases may be different.

For example, the .NET Framework implementation of the `Contains` method performs a case-sensitive comparison by default, but in SQL Server this is determined by the collation setting of the SQL Server instance. That setting defaults to case-insensitive. You could call the `ToUpper` method to make the test explicitly case-insensitive: `Where(s => s.LastName.ToUpper().Contains(searchString.ToUpper()))`. That would ensure that results stay the same if you change the code later to use a repository which returns an `IEnumerable` collection instead of an `IQueryable` object. (When you call the `Contains` method on an `IEnumerable` collection, you get the .NET Framework implementation; when you call it on an `IQueryable` object, you get the database provider implementation.) However, there's a performance penalty for this solution. The `ToUpper` code would put a function in the WHERE clause of the TSQL SELECT statement. That would prevent the optimizer from using an index. Given that SQL is mostly installed as case-insensitive, it's best to avoid the `ToUpper` code until you migrate to a case-sensitive data store.

## Add a Search Box to the Student Index View

In `Views/Student/Index.cshtml`, add the highlighted code immediately before the opening table tag in order to create a caption, a text box, and a **Search** button.

```
<p>
    <a asp-action="Create">Create New</a>
</p>

<form asp-action="Index" method="get">
    <div class="form-actions no-color">
        <p>
            Find by name: <input type="text" name="SearchString" value="@ViewData["currentFilter"]" />
            <input type="submit" value="Search" class="btn btn-default" /> |
            <a asp-action="Index">Back to Full List</a>
        </p>
    </div>
</form>

<table class="table">
```

This code uses the `<form>` tag helper to add the search text box and button. By default, the `<form>` tag helper submits form data with a POST, which means that parameters are passed in the HTTP message body and not in the URL as query strings. When you specify HTTP GET, the form data is passed in the URL as query strings, which enables users to bookmark the URL. The W3C guidelines recommend that you should use GET when the action doesn't result in an update.

Run the app, select the **Students** tab, enter a search string, and click Search to verify that filtering is working.

Last Name	First Mid Name	Enrollment Date	
Alexander	Carson	9/2/2005 12:00:00 AM	Edit   Details   Delete
Anand	Arturo	9/1/2003 12:00:00 AM	Edit   Details   Delete
Li	Yan	9/1/2002 12:00:00 AM	Edit   Details   Delete
Norman	Laura	9/1/2003 12:00:00 AM	Edit   Details   Delete

Notice that the URL contains the search string.

```
http://localhost:5813/Students?SearchString=an
```

If you bookmark this page, you'll get the filtered list when you use the bookmark. Adding `method="get"` to the `form` tag is what caused the query string to be generated.

At this stage, if you click a column heading sort link you'll lose the filter value that you entered in the **Search** box. You'll fix that in the next section.

## Add paging functionality to the Students Index page

To add paging to the Students Index page, you'll create a `PaginatedList` class that uses `Skip` and `Take` statements to filter data on the server instead of always retrieving all rows of the table. Then you'll make additional changes in the `Index` method and add paging buttons to the `Index` view. The following illustration shows the paging buttons.

The screenshot shows a web browser window with the title "Index - Contoso Univers" and the URL "localhost:5813/Student". The page header includes a back arrow, forward arrow, refresh button, and a search bar with placeholder "Find by name:" and a "Search" button. Below the header is a navigation menu with three horizontal bars. The main content area is titled "Index" and contains a "Create New" link. A search bar with placeholder "Find by name:" and a "Search" button is followed by a link "Back to Full List". A table lists student information with columns "Last Name", "First Name", and "Enrollment Date". The data rows are:

Last Name	First Name	Enrollment Date	
Alexander	Carson	9/1/2005 12:00:00 AM	Edit   Details   Delete
Alonso	Meredith	9/1/2002 12:00:00 AM	Edit   Details   Delete
Anand	Arturo	9/1/2003 12:00:00 AM	Edit   Details   Delete

At the bottom of the page are "Previous" and "Next" navigation buttons.

In the project folder, create `PaginatedList.cs`, and then replace the template code with the following code.

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Threading.Tasks;
using Microsoft.EntityFrameworkCore;

namespace ContosoUniversity
{
    public class PaginatedList<T> : List<T>
    {
        public int PageIndex { get; private set; }
        public int TotalPages { get; private set; }

        public PaginatedList(List<T> items, int count, int pageIndex, int pageSize)
        {
            PageIndex = pageIndex;
            TotalPages = (int)Math.Ceiling(count / (double)pageSize);

            this.AddRange(items);
        }

        public bool HasPreviousPage
        {
            get
            {
                return (PageIndex > 1);
            }
        }

        public bool HasNextPage
        {
            get
            {
                return (PageIndex < TotalPages);
            }
        }

        public static async Task<PaginatedList<T>> CreateAsync(IQueryable<T> source, int pageIndex, int pageSize)
        {
            var count = await source.CountAsync();
            var items = await source.Skip((pageIndex - 1) * pageSize).Take(pageSize).ToListAsync();
            return new PaginatedList<T>(items, count, pageIndex, pageSize);
        }
    }
}

```

The `CreateAsync` method in this code takes page size and page number and applies the appropriate `skip` and `Take` statements to the `IQueryable`. When `ToListAsync` is called on the `IQueryable`, it will return a List containing only the requested page. The properties `HasPreviousPage` and `HasNextPage` can be used to enable or disable **Previous** and **Next** paging buttons.

A `CreateAsync` method is used instead of a constructor to create the `PaginatedList<T>` object because constructors can't run asynchronous code.

## Add paging functionality to the Index method

In `StudentsController.cs`, replace the `Index` method with the following code.

```

public async Task<IActionResult> Index(
    string sortOrder,
    string currentFilter,
    string searchString,
    int? page)
{
    ViewData["CurrentSort"] = sortOrder;
    ViewData["NameSortParm"] = String.IsNullOrEmpty(sortOrder) ? "name_desc" : "";
    ViewData["DateSortParm"] = sortOrder == "Date" ? "date_desc" : "Date";

    if (searchString != null)
    {
        page = 1;
    }
    else
    {
        searchString = currentFilter;
    }

    ViewData["CurrentFilter"] = searchString;

    var students = from s in _context.Students
                  select s;
    if (!String.IsNullOrEmpty(searchString))
    {
        students = students.Where(s => s.LastName.Contains(searchString)
                           || s.FirstMidName.Contains(searchString));
    }
    switch (sortOrder)
    {
        case "name_desc":
            students = students.OrderByDescending(s => s.LastName);
            break;
        case "Date":
            students = students.OrderBy(s => s.EnrollmentDate);
            break;
        case "date_desc":
            students = students.OrderByDescending(s => s.EnrollmentDate);
            break;
        default:
            students = students.OrderBy(s => s.LastName);
            break;
    }

    int pageSize = 3;
    return View(await PaginatedList<Student>.CreateAsync(students.AsNoTracking(), page ?? 1, pageSize));
}

```

This code adds a page number parameter, a current sort order parameter, and a current filter parameter to the method signature.

```

public async Task<IActionResult> Index(
    string sortOrder,
    string currentFilter,
    string searchString,
    int? page)

```

The first time the page is displayed, or if the user hasn't clicked a paging or sorting link, all the parameters will be null. If a paging link is clicked, the page variable will contain the page number to display.

The `viewData` element named CurrentSort provides the view with the current sort order, because this must be included in the paging links in order to keep the sort order the same while paging.

The `viewData` element named `CurrentFilter` provides the view with the current filter string. This value must be included in the paging links in order to maintain the filter settings during paging, and it must be restored to the text box when the page is redisplayed.

If the search string is changed during paging, the page has to be reset to 1, because the new filter can result in different data to display. The search string is changed when a value is entered in the text box and the Submit button is pressed. In that case, the `searchString` parameter isn't null.

```
if (searchString != null)
{
    page = 1;
}
else
{
    searchString = currentFilter;
}
```

At the end of the `Index` method, the `PaginatedList.CreateAsync` method converts the student query to a single page of students in a collection type that supports paging. That single page of students is then passed to the view.

```
return View(await PaginatedList<Student>.CreateAsync(students.AsNoTracking(), page ?? 1, pageSize));
```

The `PaginatedList.CreateAsync` method takes a page number. The two question marks represent the null-coalescing operator. The null-coalescing operator defines a default value for a nullable type; the expression `(page ?? 1)` means return the value of `page` if it has a value, or return 1 if `page` is null.

## Add paging links to the Student Index view

In `Views/Students/Index.cshtml`, replace the existing code with the following code. The changes are highlighted.

```
@model PaginatedList<ContosoUniversity.Models.Student>

@{
    ViewData["Title"] = "Index";
}

## Index

Create New

<form asp-action="Index" method="get">
    <div class="form-actions no-color">
        <p>
            Find by name: <input type="text" name="SearchString" value="@ViewData["currentFilter"]" />
            <input type="submit" value="Search" class="btn btn-default" /> |
            <a href="#">Back to Full List

    <tr>
        <th>
            <a href="#" asp-route-sortOrder="@ViewData["NameSortParm]" asp-route-currentFilter="@ViewData["CurrentFilter"]">Last Name</a>
        </th>
        <th>
            First Name
        </th>
    </tr>

    <tr>
        <td>
            <a href="#" asp-route-sortOrder="@ViewData["NameSortParm]" asp-route-currentFilter="@ViewData["CurrentFilter"]">Last Name</a>
        </td>
        <td>
            First Name
        </td>
    </tr>

```

```

| <a asp-action="Index" asp-route-currentfilter="@ViewData[" asp-route-sortorder="@ViewData[" currentfilter"]"="" datesortparm]"="" href="#">Enrollment Date</a> |  |  |  |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|
|                                                                                                                                                                |  |  |  |

@foreach (var item in Model)
    {
        <tr>
            <td>
                @Html.DisplayFor(modelItem => item.LastName)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.FirstMidName)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.EnrollmentDate)
            </td>
            <td>
                <a href="#" asp-action="Edit" asp-route-id="@item.ID">Edit</a> | 
                <a href="#" asp-action="Details" asp-route-id="@item.ID">Details</a> | 
                <a href="#" asp-action="Delete" asp-route-id="@item.ID">Delete</a>
            </td>
        </tr>
    }

@{
        var prevDisabled = !Model.HasPreviousPage ? "disabled" : "";
        var nextDisabled = !Model.HasNextPage ? "disabled" : "";
    }

Previous
  

Next

```

The `@model` statement at the top of the page specifies that the view now gets a `PaginatedList<T>` object instead of a `List<T>` object.

The column header links use the query string to pass the current search string to the controller so that the user can sort within filter results:

```

<a href="#" asp-action="Index" asp-route-sortOrder="@ViewData["DateSortParm]" asp-route-currentFilter="@ViewData["CurrentFilter"]">Enrollment Date

```

The paging buttons are displayed by tag helpers:

```

<a asp-action="Index"
asp-route-sortOrder="@ViewData["CurrentSort"]"
asp-route-page="@(ModelPageIndex - 1)"
asp-route-currentFilter="@ViewData["CurrentFilter"]"
class="btn btn-default @prevDisabled">
Previous
</a>

```

Run the app and go to the Students page.

Last Name	First Name	Enrollment Date	
Alexander	Carson	9/1/2005 12:00:00 AM	Edit   Details   Delete
Alonso	Meredith	9/1/2002 12:00:00 AM	Edit   Details   Delete
Anand	Arturo	9/1/2003 12:00:00 AM	Edit   Details   Delete

Click the paging links in different sort orders to make sure paging works. Then enter a search string and try paging again to verify that paging also works correctly with sorting and filtering.

## Create an About page that shows Student statistics

For the Contoso University website's **About** page, you'll display how many students have enrolled for each enrollment date. This requires grouping and simple calculations on the groups. To accomplish this, you'll do the following:

- Create a view model class for the data that you need to pass to the view.
- Modify the About method in the Home controller.
- Modify the About view.

### Create the view model

Create a *SchoolViewModels* folder in the *Models* folder.

In the new folder, add a class file *EnrollmentDateGroup.cs* and replace the template code with the following code:

```

using System;
using System.ComponentModel.DataAnnotations;

namespace ContosoUniversity.Models.SchoolViewModels
{
    public class EnrollmentDateGroup
    {
        [DataType(DataType.Date)]
        public DateTime? EnrollmentDate { get; set; }

        public int StudentCount { get; set; }
    }
}

```

## Modify the Home Controller

In *HomeController.cs*, add the following using statements at the top of the file:

```

using Microsoft.EntityFrameworkCore;
using ContosoUniversity.Data;
using ContosoUniversity.Models.SchoolViewModels;

```

Add a class variable for the database context immediately after the opening curly brace for the class, and get an instance of the context from ASP.NET Core DI:

```

public class HomeController : Controller
{
    private readonly SchoolContext _context;

    public HomeController(SchoolContext context)
    {
        _context = context;
    }
}

```

Replace the `About` method with the following code:

```

public async Task<ActionResult> About()
{
    IQueryable<EnrollmentDateGroup> data =
        from student in _context.Students
        group student by student.EnrollmentDate into dateGroup
        select new EnrollmentDateGroup()
    {
        EnrollmentDate = dateGroup.Key,
        StudentCount = dateGroup.Count()
    };
    return View(await data.AsNoTracking().ToListAsync());
}

```

The LINQ statement groups the student entities by enrollment date, calculates the number of entities in each group, and stores the results in a collection of `EnrollmentDateGroup` view model objects.

### NOTE

In the 1.0 version of Entity Framework Core, the entire result set is returned to the client, and grouping is done on the client. In some scenarios this could create performance problems. Be sure to test performance with production volumes of data, and if necessary use raw SQL to do the grouping on the server. For information about how to use raw SQL, see [the last tutorial in this series](#).

## Modify the About View

Replace the code in the `Views/Home/About.cshtml` file with the following code:

```
@model IEnumerable<ContosoUniversity.Models.SchoolViewModels.EnrollmentDateGroup>

@{
    ViewData["Title"] = "Student Body Statistics";
}

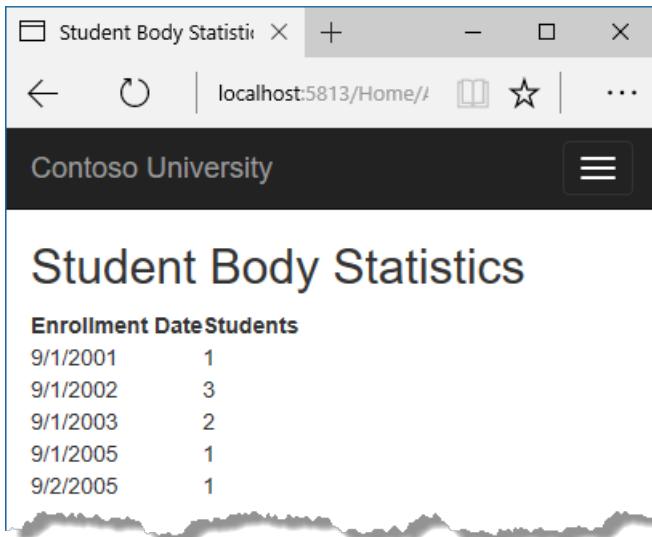

## Student Body Statistics

| Enrollment Date | Students |
|-----------------|----------|
|-----------------|----------|

```

Run the app and go to the About page. The count of students for each enrollment date is displayed in a table.

## Summary

In this tutorial, you've seen how to perform sorting, filtering, paging, and grouping. In the next tutorial, you'll learn how to handle data model changes by using migrations.

# ASP.NET Core MVC with EF Core - Migrations - 4 of 10

6/28/2018 • 8 minutes to read • [Edit Online](#)

This tutorial has not been upgraded to ASP.NET Core 2.1. The ASP.NET Core 2.0 version of this tutorial is available by selecting **ASP.NET Core 2.0** above the table of contents or at the top of the page:

The ASP.NET Core 2.1 Razor Pages version of this tutorial has many improvements over the 2.0 version.

The 2.0 tutorial teaches ASP.NET Core MVC and Entity Framework Core with controllers and views. Razor Pages is a page-based programming model that makes building web UI easier and more productive. We recommend the [Razor Pages](#) tutorial over the MVC version. The Razor Pages tutorial:

- Is easier to follow. For example, the scaffolding code has been significantly simplified.
- Provides more EF Core best practices.
- Uses more efficient queries.
- Is more current with the latest API.
- Covers more features.
- Is the preferred approach for new application development.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub discussion](#).

By [Tom Dykstra](#) and [Rick Anderson](#)

The Contoso University sample web application demonstrates how to create ASP.NET Core MVC web applications using Entity Framework Core and Visual Studio. For information about the tutorial series, see [the first tutorial in the series](#).

In this tutorial, you start using the EF Core migrations feature for managing data model changes. In later tutorials, you'll add more migrations as you change the data model.

## Introduction to migrations

When you develop a new application, your data model changes frequently, and each time the model changes, it gets out of sync with the database. You started these tutorials by configuring the Entity Framework to create the database if it doesn't exist. Then each time you change the data model -- add, remove, or change entity classes or change your DbContext class -- you can delete the database and EF creates a new one that matches the model, and seeds it with test data.

This method of keeping the database in sync with the data model works well until you deploy the application to production. When the application is running in production it's usually storing data that you want to keep, and you don't want to lose everything each time you make a change such as adding a new column. The EF Core Migrations feature solves this problem by enabling EF to update the database schema instead of creating a new database.

## Entity Framework Core NuGet packages for migrations

To work with migrations, you can use the **Package Manager Console** (PMC) or the command-line interface (CLI). These tutorials show how to use CLI commands. Information about the PMC is at [the end of this tutorial](#).

The EF tools for the command-line interface (CLI) are provided in [Microsoft.EntityFrameworkCore.Tools.DotNet](#).

To install this package, add it to the `DotNetCliToolReference` collection in the `.csproj` file, as shown. **Note:** You have to install this package by editing the `.csproj` file; you can't use the `install-package` command or the package manager GUI. You can edit the `.csproj` file by right-clicking the project name in **Solution Explorer** and selecting **Edit ContosoUniversity.csproj**.

```
<ItemGroup>
  <DotNetCliToolReference Include="Microsoft.EntityFrameworkCore.Tools.DotNet" Version="2.0.0" />
  <DotNetCliToolReference Include="Microsoft.VisualStudio.Web.CodeGeneration.Tools" Version="2.0.0" />
</ItemGroup>
```

(The version numbers in this example were current when the tutorial was written.)

## Change the connection string

In the `appsettings.json` file, change the name of the database in the connection string to `ContosoUniversity2` or some other name that you haven't used on the computer you're using.

```
{
  "ConnectionStrings": {
    "DefaultConnection": "Server=(localdb)\\mssqllocaldb;Database=ContosoUniversity2;Trusted_Connection=True;MultipleActiveResultSets=true"
  },
}
```

This change sets up the project so that the first migration will create a new database. This isn't required to get started with migrations, but you'll see later why it's a good idea.

### NOTE

As an alternative to changing the database name, you can delete the database. Use **SQL Server Object Explorer** (SSOX) or the `database drop` CLI command:

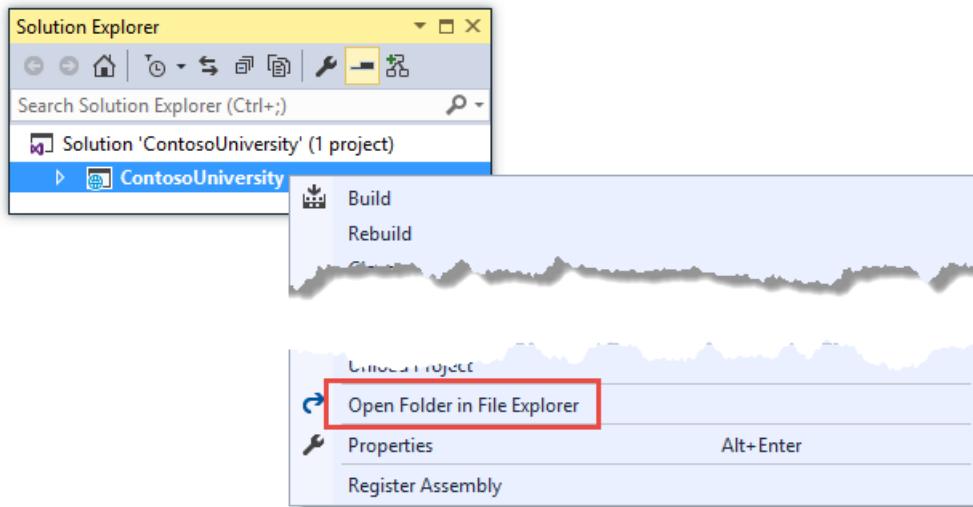

```
dotnet ef database drop
```

The following section explains how to run CLI commands.

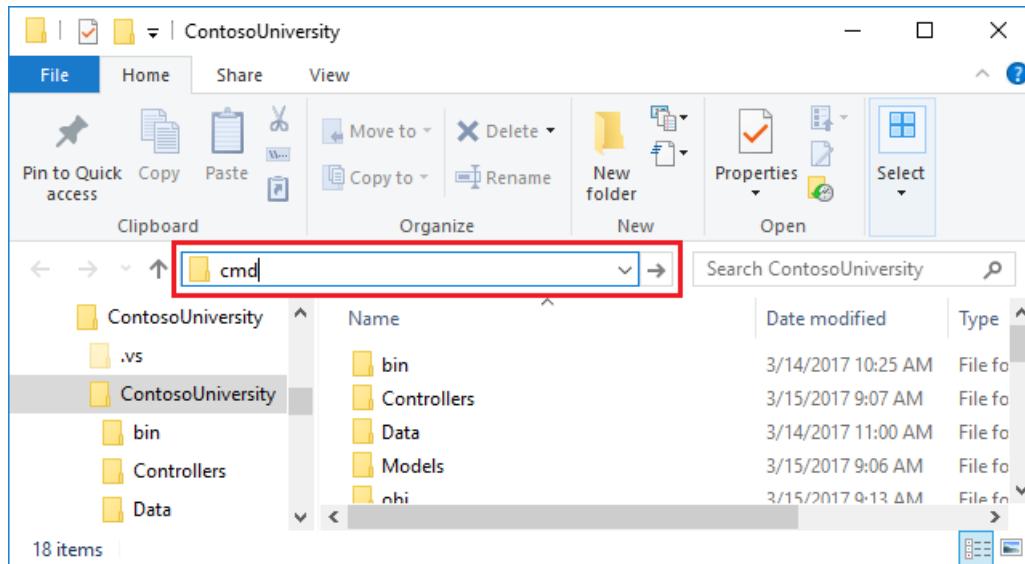

## Create an initial migration

Save your changes and build the project. Then open a command window and navigate to the project folder. Here's a quick way to do that:

- In **Solution Explorer**, right-click the project and choose **Open in File Explorer** from the context menu.

- Enter "cmd" in the address bar and press Enter.

Enter the following command in the command window:

```
dotnet ef migrations add InitialCreate
```

You see output like the following in the command window:

```
info: Microsoft.AspNetCore.DataProtection.KeyManagement.XmlKeyManager[0]
User profile is available. Using 'C:\Users\username\AppData\Local\ASP.NET\DataProtection-Keys' as key
repository and Windows DPAPI to encrypt keys at rest.
info: Microsoft.EntityFrameworkCore.Infrastructure[100403]
Entity Framework Core 2.0.0-rtm-26452 initialized 'SchoolContext' using provider
'Microsoft.EntityFrameworkCore.SqlServer' with options: None
Done. To undo this action, use 'ef migrations remove'
```

#### NOTE

If you see an error message *No executable found matching command "dotnet-ef"*, see [this blog post](#) for help troubleshooting.

If you see an error message "*cannot access the file ... ContosoUniversity.dll because it is being used by another process.*", find the IIS Express icon in the Windows System Tray, and right-click it, then click **ContosoUniversity > Stop Site**.

## Examine the Up and Down methods

When you executed the `migrations add` command, EF generated the code that will create the database from scratch. This code is in the *Migrations* folder, in the file named `<timestamp>_InitialCreate.cs`. The `Up` method of the `InitialCreate` class creates the database tables that correspond to the data model entity sets, and the `Down` method deletes them, as shown in the following example.

```
public partial class InitialCreate : Migration
{
    protected override void Up(MigrationBuilder migrationBuilder)
    {
        migrationBuilder.CreateTable(
            name: "Course",
            columns: table => new
            {
                CourseID = table.Column<int>(nullable: false),
                Credits = table.Column<int>(nullable: false),
                Title = table.Column<string>(nullable: true)
            },
            constraints: table =>
            {
                table.PrimaryKey("PK_Course", x => x.CourseID);
            });
    }

    // Additional code not shown
}

protected override void Down(MigrationBuilder migrationBuilder)
{
    migrationBuilder.DropTable(
        name: "Enrollment");
    // Additional code not shown
}
```

Migrations calls the `Up` method to implement the data model changes for a migration. When you enter a command to roll back the update, Migrations calls the `Down` method.

This code is for the initial migration that was created when you entered the `migrations add InitialCreate` command. The migration name parameter ("InitialCreate" in the example) is used for the file name and can be whatever you want. It's best to choose a word or phrase that summarizes what is being done in the migration. For example, you might name a later migration "AddDepartmentTable".

If you created the initial migration when the database already exists, the database creation code is generated but it doesn't have to run because the database already matches the data model. When you deploy the app to another environment where the database doesn't exist yet, this code will run to create your database, so it's a good idea to test it first. That's why you changed the name of the database in the connection string earlier -- so that migrations can create a new one from scratch.

## The data model snapshot

Migrations creates a *snapshot* of the current database schema in `Migrations/SchoolContextModelSnapshot.cs`. When you add a migration, EF determines what changed by comparing the data model to the snapshot file.

When deleting a migration, use the `dotnet ef migrations remove` command. `dotnet ef migrations remove` deletes the migration and ensures the snapshot is correctly reset.

See [EF Core Migrations in Team Environments](#) for more information about how the snapshot file is used.

## Apply the migration to the database

In the command window, enter the following command to create the database and tables in it.

```
dotnet ef database update
```

The output from the command is similar to the `migrations add` command, except that you see logs for the SQL commands that set up the database. Most of the logs are omitted in the following sample output. If you prefer not to see this level of detail in log messages, you can change the log level in the `appsettings.Development.json` file. For more information, see [Introduction to logging](#).

```
info: Microsoft.AspNetCore.DataProtection.KeyManagement.XmlKeyManager[0]
User profile is available. Using 'C:\Users\username\AppData\Local\ASP.NET\DataProtection-Keys' as key
repository and Windows DPAPI to encrypt keys at rest.
info: Microsoft.EntityFrameworkCore.Infrastructure[100403]
Entity Framework Core 2.0.0-rtm-26452 initialized 'SchoolContext' using provider
'Microsoft.EntityFrameworkCore.SqlServer' with options: None
info: Microsoft.EntityFrameworkCore.Database.Command[200101]

CREATE DATABASE [ContosoUniversity2];
info: Microsoft.EntityFrameworkCore.Database.Command[200101]
Executed DbCommand (20ms) [Parameters=[], CommandType='Text', CommandTimeout='30']
CREATE TABLE [__EFMigrationsHistory] (
[MigrationId] nvarchar(150) NOT NULL,
[ProductVersion] nvarchar(32) NOT NULL,
CONSTRAINT [PK__EFMigrationsHistory] PRIMARY KEY ([MigrationId])
);

<logs omitted for brevity>

info: Microsoft.EntityFrameworkCore.Database.Command[200101]
Executed DbCommand (3ms) [Parameters=[], CommandType='Text', CommandTimeout='30']
INSERT INTO [__EFMigrationsHistory] ([MigrationId], [ProductVersion])
VALUES (N'20170816151242_InitialCreate', N'2.0.0-rtm-26452');
Done.
```

Use **SQL Server Object Explorer** to inspect the database as you did in the first tutorial. You'll notice the addition of an `__EFMigrationsHistory` table that keeps track of which migrations have been applied to the database. View the data in that table and you'll see one row for the first migration. (The last log in the preceding CLI output example shows the `INSERT` statement that creates this row.)

Run the application to verify that everything still works the same as before.

The screenshot shows a web browser window with the title "Index - Contoso University". The address bar indicates the URL is "localhost:5813/Student". The main content area is titled "Contoso University" and features a heading "Index". Below the heading is a "Create New" link. A search bar with the placeholder "Find by name:" and a "Search" button is present. A "Back to Full List" link is also visible. The data is presented in a table format with three columns: "Last Name", "First Name", and "Enrollment Date". The table contains three rows of data:

Last Name	First Name	Enrollment Date
Alexander	Carson	9/1/2005 12:00:00 AM
Alonso	Meredith	9/1/2002 12:00:00 AM
Anand	Arturo	9/1/2003 12:00:00 AM

Each row has "Edit | Details | Delete" links. At the bottom of the table are "Previous" and "Next" navigation buttons.

## Command-line interface (CLI) vs. Package Manager Console (PMC)

The EF tooling for managing migrations is available from .NET Core CLI commands or from PowerShell cmdlets in the Visual Studio **Package Manager Console** (PMC) window. This tutorial shows how to use the CLI, but you can use the PMC if you prefer.

The EF commands for the PMC commands are in the [Microsoft.EntityFrameworkCore.Tools](#) package. This package is already included in the [Microsoft.AspNetCore.All](#) metapackage, so you don't have to install it.

**Important:** This isn't the same package as the one you install for the CLI by editing the `.csproj` file. The name of this one ends in `Tools`, unlike the CLI package name which ends in `Tools.DotNet`.

For more information about the CLI commands, see [.NET Core CLI](#).

For more information about the PMC commands, see [Package Manager Console \(Visual Studio\)](#).

## Summary

In this tutorial, you've seen how to create and apply your first migration. In the next tutorial, you'll begin looking at more advanced topics by expanding the data model. Along the way you'll create and apply additional migrations.

# ASP.NET Core MVC with EF Core - Data Model - 5 of 10

6/28/2018 • 31 minutes to read • [Edit Online](#)

This tutorial has not been upgraded to ASP.NET Core 2.1. The ASP.NET Core 2.0 version of this tutorial is available by selecting **ASP.NET Core 2.0** above the table of contents or at the top of the page:

The ASP.NET Core 2.1 Razor Pages version of this tutorial has many improvements over the 2.0 version.

The 2.0 tutorial teaches ASP.NET Core MVC and Entity Framework Core with controllers and views. Razor Pages is a page-based programming model that makes building web UI easier and more productive. We recommend the [Razor Pages](#) tutorial over the MVC version. The Razor Pages tutorial:

- Is easier to follow. For example, the scaffolding code has been significantly simplified.
- Provides more EF Core best practices.
- Uses more efficient queries.
- Is more current with the latest API.
- Covers more features.
- Is the preferred approach for new application development.

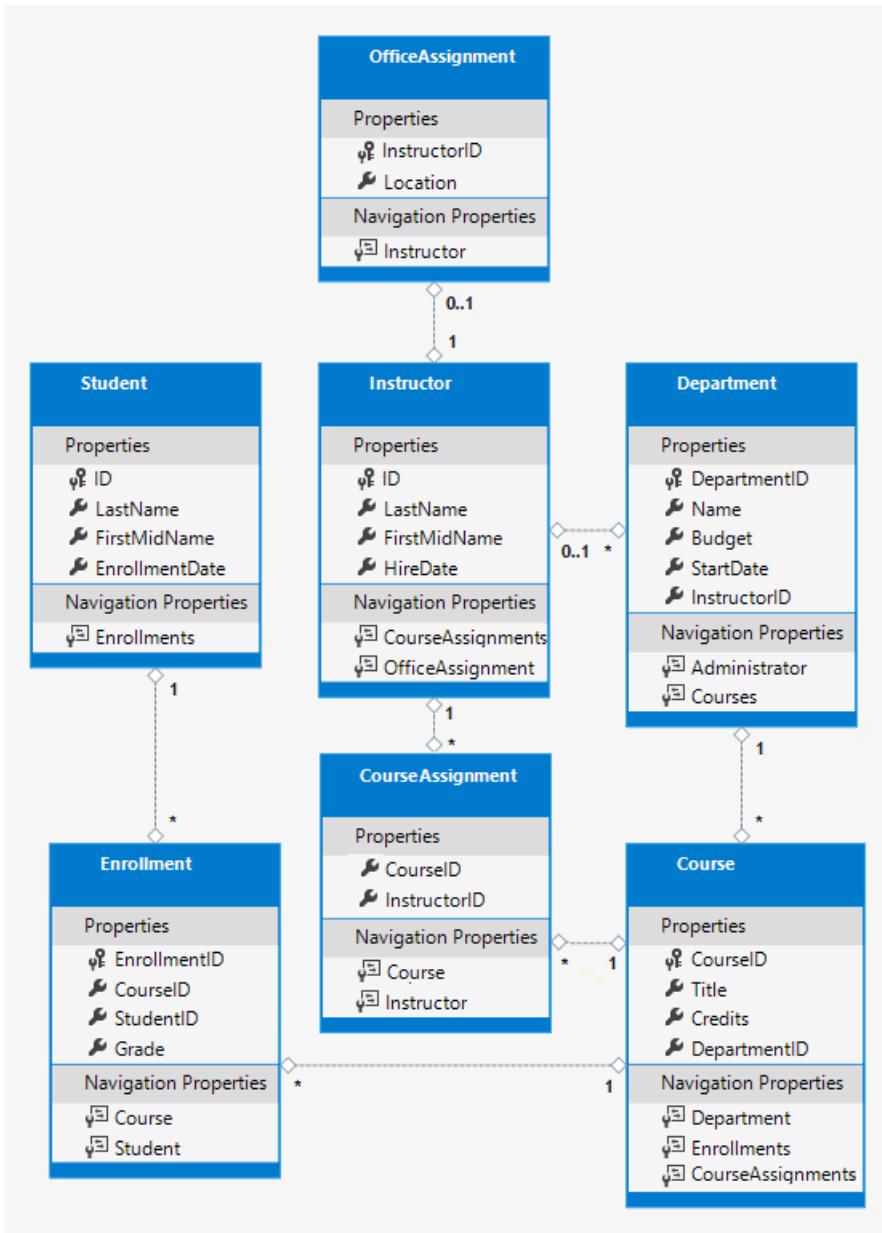

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub discussion](#).

By [Tom Dykstra](#) and [Rick Anderson](#)

The Contoso University sample web application demonstrates how to create ASP.NET Core MVC web applications using Entity Framework Core and Visual Studio. For information about the tutorial series, see [the first tutorial in the series](#).

In the previous tutorials, you worked with a simple data model that was composed of three entities. In this tutorial, you'll add more entities and relationships and you'll customize the data model by specifying formatting, validation, and database mapping rules.

When you're finished, the entity classes will make up the completed data model that's shown in the following illustration:

## Customize the Data Model by Using Attributes

In this section you'll see how to customize the data model by using attributes that specify formatting, validation, and database mapping rules. Then in several of the following sections you'll create the complete School data model by adding attributes to the classes you already created and creating new classes for the remaining entity types in the model.

### The `DataType` attribute

For student enrollment dates, all of the web pages currently display the time along with the date, although all you care about for this field is the date. By using data annotation attributes, you can make one code change that will fix the display format in every view that shows the data. To see an example of how to do that, you'll add an attribute to the `EnrollmentDate` property in the `Student` class.

In `Models/Student.cs`, add a `using` statement for the `System.ComponentModel.DataAnnotations` namespace and add `DataType` and `DisplayFormat` attributes to the `EnrollmentDate` property, as shown in the following example:

```

using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;

namespace ContosoUniversity.Models
{
    public class Student
    {
        public int ID { get; set; }
        public string LastName { get; set; }
        public string FirstMidName { get; set; }
        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        public DateTime EnrollmentDate { get; set; }

        public ICollection<Enrollment> Enrollments { get; set; }
    }
}

```

The `DataType` attribute is used to specify a data type that's more specific than the database intrinsic type. In this case we only want to keep track of the date, not the date and time. The `DataType` Enumeration provides for many data types, such as Date, Time, PhoneNumber, Currency, EmailAddress, and more. The `DataType` attribute can also enable the application to automatically provide type-specific features. For example, a `mailto:` link can be created for `DataType.EmailAddress`, and a date selector can be provided for `DataType.Date` in browsers that support HTML5. The `DataType` attribute emits HTML 5 `data-` (pronounced data dash) attributes that HTML 5 browsers can understand. The `DataType` attributes don't provide any validation.

`DataType.Date` doesn't specify the format of the date that's displayed. By default, the data field is displayed according to the default formats based on the server's `CultureInfo`.

The `DisplayFormat` attribute is used to explicitly specify the date format:

```
[DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
```

The `ApplyFormatInEditMode` setting specifies that the formatting should also be applied when the value is displayed in a text box for editing. (You might not want that for some fields -- for example, for currency values, you might not want the currency symbol in the text box for editing.)

You can use the `DisplayFormat` attribute by itself, but it's generally a good idea to use the `DataType` attribute also. The `DataType` attribute conveys the semantics of the data as opposed to how to render it on a screen, and provides the following benefits that you don't get with `DisplayFormat`:

- The browser can enable HTML5 features (for example to show a calendar control, the locale-appropriate currency symbol, email links, some client-side input validation, etc.).
- By default, the browser will render data using the correct format based on your locale.

For more information, see the [<input> tag helper documentation](#).

Run the app, go to the Students Index page and notice that times are no longer displayed for the enrollment dates. The same will be true for any view that uses the Student model.

Last Name	First Name	Enrollment Date	
Alexander	Carson	2005-09-01	Edit   Details   Delete
Alonso	Meredith	2002-09-01	Edit   Details   Delete
Anand	Arturo	2003-09-01	Edit   Details   Delete

## The StringLength attribute

You can also specify data validation rules and validation error messages using attributes. The `StringLength` attribute sets the maximum length in the database and provides client side and server side validation for ASP.NET MVC. You can also specify the minimum string length in this attribute, but the minimum value has no impact on the database schema.

Suppose you want to ensure that users don't enter more than 50 characters for a name. To add this limitation, add `StringLength` attributes to the `LastName` and `FirstMidName` properties, as shown in the following example:

```
using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;

namespace ContosoUniversity.Models
{
    public class Student
    {
        public int ID { get; set; }
        [StringLength(50)]
        public string LastName { get; set; }
        [StringLength(50, ErrorMessage = "First name cannot be longer than 50 characters.")]
        public string FirstMidName { get; set; }
        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        public DateTime EnrollmentDate { get; set; }

        public ICollection<Enrollment> Enrollments { get; set; }
    }
}
```

The `StringLength` attribute won't prevent a user from entering white space for a name. You can use the `RegularExpression` attribute to apply restrictions to the input. For example, the following code requires the first character to be upper case and the remaining characters to be alphabetical:

```
[RegularExpression(@"^([A-Z]+[a-zA-Z'''\s-]*)$")]
```

The `MaxLength` attribute provides functionality similar to the `StringLength` attribute but doesn't provide client side validation.

The database model has now changed in a way that requires a change in the database schema. You'll use migrations to update the schema without losing any data that you may have added to the database by using the application UI.

Save your changes and build the project. Then open the command window in the project folder and enter the following commands:

```
dotnet ef migrations add MaxLengthOnNames
```

```
dotnet ef database update
```

The `migrations add` command warns that data loss may occur, because the change makes the maximum length shorter for two columns. Migrations creates a file named `<timeStamp>_MaxLengthOnNames.cs`. This file contains code in the `Up` method that will update the database to match the current data model. The `database update` command ran that code.

The timestamp prefixed to the migrations file name is used by Entity Framework to order the migrations. You can create multiple migrations before running the update-database command, and then all of the migrations are applied in the order in which they were created.

Run the app, select the **Students** tab, click **Create New**, and enter either name longer than 50 characters. When you click **Create**, client side validation shows an error message.

The screenshot shows a browser window with the following details:

- Title Bar:** Create - Contoso University
- Address Bar:** localhost:5813/Student
- Page Title:** Contoso University
- Form Title:** Create
- Form Fields:**
  - Last Name:** Davolio very long last name longer than !  
Error: The field LastName must be a string with a maximum length of 50.
  - First Mid Name:** Nancy very long first name longer than 5  
Error: First name cannot be longer than 50 characters.
  - Enrollment Date:** 2/15/2017
- Buttons:** Create

## The Column attribute

You can also use attributes to control how your classes and properties are mapped to the database. Suppose you had used the name `FirstMidName` for the first-name field because the field might also contain a middle name. But you want the database column to be named `FirstName`, because users who will be writing ad-hoc queries against the database are accustomed to that name. To make this mapping, you can use the `Column` attribute.

The `Column` attribute specifies that when the database is created, the column of the `Student` table that maps to the `FirstMidName` property will be named `FirstName`. In other words, when your code refers to `Student.FirstMidName`, the data will come from or be updated in the `FirstName` column of the `Student` table. If you don't specify column names, they're given the same name as the property name.

In the `Student.cs` file, add a `using` statement for `System.ComponentModel.DataAnnotations.Schema` and add the column name attribute to the `FirstMidName` property, as shown in the following highlighted code:

```
using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Student
    {
        public int ID { get; set; }
        [StringLength(50)]
        public string LastName { get; set; }
        [StringLength(50, ErrorMessage = "First name cannot be longer than 50 characters.")]  

        [Column("FirstName")]
        public string FirstMidName { get; set; }
        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        public DateTime EnrollmentDate { get; set; }

        public ICollection<Enrollment> Enrollments { get; set; }
    }
}
```

The addition of the `Column` attribute changes the model backing the `SchoolContext`, so it won't match the database.

Save your changes and build the project. Then open the command window in the project folder and enter the following commands to create another migration:

```
dotnet ef migrations add ColumnFirstName
```

```
dotnet ef database update
```

In **SQL Server Object Explorer**, open the Student table designer by double-clicking the **Student** table.

	Name	Data Type	Allow Nulls
ID	int		
EnrollmentDate	datetime2(7)		
FirstName	nvarchar(50)	<input checked="" type="checkbox"/>	
LastName	nvarchar(50)	<input checked="" type="checkbox"/>	

Keys (1)  
PK\_Students (Primary Key, Clu)  
Check Constraints (0)  
Indexes (0)  
Foreign Keys (0)  
Triggers (0)

Design    T-SQL

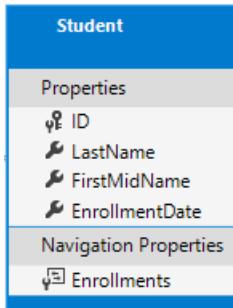

```
1  CREATE TABLE [dbo].[Students] (
2      [ID]           INT            IDENTITY (1, 1) NOT NULL,
3      [EnrollmentDate] DATETIME2 (7) NOT NULL,
4      [FirstName]      NVARCHAR (50) NULL,
5      [LastName]       NVARCHAR (50) NULL,
6      CONSTRAINT [PK_Students] PRIMARY KEY CLUSTERED ([ID] ASC)
7  );
8
```

Before you applied the first two migrations, the name columns were of type nvarchar(MAX). They're now nvarchar(50) and the column name has changed from FirstMidName to FirstName.

**NOTE**

If you try to compile before you finish creating all of the entity classes in the following sections, you might get compiler errors.

## Final changes to the Student entity

In *Models/Student.cs*, replace the code you added earlier with the following code. The changes are highlighted.

```

using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Student
    {
        public int ID { get; set; }

        [Required]
        [StringLength(50)]
        [Display(Name = "Last Name")]
        public string LastName { get; set; }

        [Required]
        [StringLength(50, ErrorMessage = "First name cannot be longer than 50 characters.")]
        [Column("FirstName")]
        [Display(Name = "First Name")]
        public string FirstMidName { get; set; }

        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        [Display(Name = "Enrollment Date")]
        public DateTime EnrollmentDate { get; set; }

        [Display(Name = "Full Name")]
        public string FullName
        {
            get
            {
                return LastName + ", " + FirstMidName;
            }
        }
    }

    public ICollection<Enrollment> Enrollments { get; set; }
}
}

```

## The Required attribute

The `Required` attribute makes the name properties required fields. The `Required` attribute isn't needed for non-nullable types such as value types (DateTime, int, double, float, etc.). Types that can't be null are automatically treated as required fields.

You could remove the `Required` attribute and replace it with a minimum length parameter for the `StringLength` attribute:

```

[Display(Name = "Last Name")]
[StringLength(50, MinimumLength=1)]
public string LastName { get; set; }

```

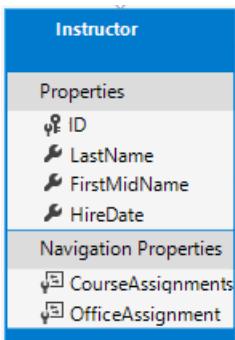

## The Display attribute

The `Display` attribute specifies that the caption for the text boxes should be "First Name", "Last Name", "Full Name", and "Enrollment Date" instead of the property name in each instance (which has no space dividing the words).

## The FullName calculated property

`FullName` is a calculated property that returns a value that's created by concatenating two other properties. Therefore it has only a get accessor, and no `FullName` column will be generated in the database.

# Create the Instructor Entity

Create `Models/Instructor.cs`, replacing the template code with the following code:

```

using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Instructor
    {
        public int ID { get; set; }

        [Required]
        [Display(Name = "Last Name")]
        [StringLength(50)]
        public string LastName { get; set; }

        [Required]
        [Column("FirstName")]
        [Display(Name = "First Name")]
        [StringLength(50)]
        public string FirstMidName { get; set; }

        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        [Display(Name = "Hire Date")]
        public DateTime HireDate { get; set; }

        [Display(Name = "Full Name")]
        public string FullName
        {
            get { return LastName + ", " + FirstMidName; }
        }

        public ICollection<CourseAssignment> CourseAssignments { get; set; }
        public OfficeAssignment OfficeAssignment { get; set; }
    }
}

```

Notice that several properties are the same in the Student and Instructor entities. In the [Implementing Inheritance](#) tutorial later in this series, you'll refactor this code to eliminate the redundancy.

You can put multiple attributes on one line, so you could also write the `HireDate` attributes as follows:

```
[DataType(DataType.Date),Display(Name = "Hire Date"),DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
```

## The `CourseAssignments` and `OfficeAssignment` navigation properties

The `CourseAssignments` and `OfficeAssignment` properties are navigation properties.

An instructor can teach any number of courses, so `CourseAssignments` is defined as a collection.

```
public ICollection<CourseAssignment> CourseAssignments { get; set; }
```

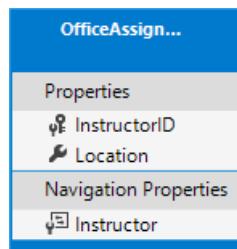

If a navigation property can hold multiple entities, its type must be a list in which entries can be added, deleted, and updated. You can specify `ICollection<T>` or a type such as `List<T>` or `HashSet<T>`. If you specify `ICollection<T>`, EF creates a `HashSet<T>` collection by default.

The reason why these are `CourseAssignment` entities is explained below in the section about many-to-many relationships.

Contoso University business rules state that an instructor can only have at most one office, so the `OfficeAssignment` property holds a single `OfficeAssignment` entity (which may be null if no office is assigned).

```
public OfficeAssignment OfficeAssignment { get; set; }
```

## Create the `OfficeAssignment` entity

Create `Models/OfficeAssignment.cs` with the following code:

```
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class OfficeAssignment
    {
        [Key]
        public int InstructorID { get; set; }
        [StringLength(50)]
        [Display(Name = "Office Location")]
        public string Location { get; set; }

        public Instructor Instructor { get; set; }
    }
}
```

### The `Key` attribute

There's a one-to-zero-or-one relationship between the `Instructor` and the `OfficeAssignment` entities. An office assignment only exists in relation to the instructor it's assigned to, and therefore its primary key is also its foreign key to the `Instructor` entity. But the Entity Framework can't automatically recognize `InstructorID` as the primary key of this entity because its name doesn't follow the `ID` or `classnameID` naming convention. Therefore, the `Key` attribute is used to identify it as the key:

```
[Key]
public int InstructorID { get; set; }
```

You can also use the `Key` attribute if the entity does have its own primary key but you want to name the property something other than `classnameID` or `ID`.

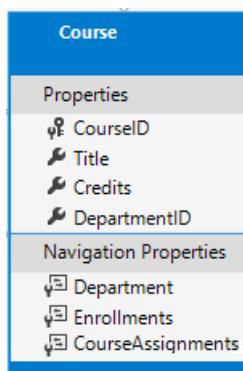

By default, EF treats the key as non-database-generated because the column is for an identifying relationship.

### The Instructor navigation property

The Instructor entity has a nullable `OfficeAssignment` navigation property (because an instructor might not have an office assignment), and the OfficeAssignment entity has a non-nullable `Instructor` navigation property (because an office assignment can't exist without an instructor -- `InstructorID` is non-nullable). When an Instructor entity has a related OfficeAssignment entity, each entity will have a reference to the other one in its navigation property.

You could put a `[Required]` attribute on the Instructor navigation property to specify that there must be a related instructor, but you don't have to do that because the `InstructorID` foreign key (which is also the key to this table) is non-nullable.

## Modify the Course Entity

In `Models/Course.cs`, replace the code you added earlier with the following code. The changes are highlighted.

```
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Course
    {
        [DatabaseGenerated(DatabaseGeneratedOption.None)]
        [Display(Name = "Number")]
        public int CourseID { get; set; }

        [StringLength(50, MinimumLength = 3)]
        public string Title { get; set; }

        [Range(0, 5)]
        public int Credits { get; set; }

        public int DepartmentID { get; set; }

        public Department Department { get; set; }
        public ICollection<Enrollment> Enrollments { get; set; }
        public ICollection<CourseAssignment> CourseAssignments { get; set; }
    }
}
```

The course entity has a foreign key property `DepartmentID` which points to the related Department entity and it has a `Department` navigation property.

The Entity Framework doesn't require you to add a foreign key property to your data model when you have a navigation property for a related entity. EF automatically creates foreign keys in the database wherever they're needed and creates [shadow properties](#) for them. But having the foreign key in the data model can make updates simpler and more efficient. For example, when you fetch a course entity to edit, the Department entity is null if you don't load it, so when you update the course entity, you would have to first fetch the Department entity.

When the foreign key property `DepartmentID` is included in the data model, you don't need to fetch the Department entity before you update.

### The `DatabaseGenerated` attribute

The `DatabaseGenerated` attribute with the `None` parameter on the `CourseID` property specifies that primary key values are provided by the user rather than generated by the database.

```
[DatabaseGenerated(DatabaseGeneratedOption.None)]
[Display(Name = "Number")]
public int CourseID { get; set; }
```

By default, Entity Framework assumes that primary key values are generated by the database. That's what you want in most scenarios. However, for Course entities, you'll use a user-specified course number such as a 1000 series for one department, a 2000 series for another department, and so on.

The `DatabaseGenerated` attribute can also be used to generate default values, as in the case of database columns used to record the date a row was created or updated. For more information, see [Generated Properties](#).

### Foreign key and navigation properties

The foreign key properties and navigation properties in the Course entity reflect the following relationships:

A course is assigned to one department, so there's a `DepartmentID` foreign key and a `Department` navigation property for the reasons mentioned above.

```
public int DepartmentID { get; set; }
public Department Department { get; set; }
```

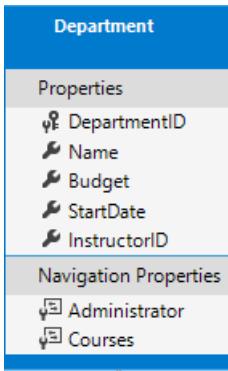

A course can have any number of students enrolled in it, so the `Enrollments` navigation property is a collection:

```
public ICollection<Enrollment> Enrollments { get; set; }
```

A course may be taught by multiple instructors, so the `CourseAssignments` navigation property is a collection (the type `CourseAssignment` is explained [later](#)):

```
public ICollection<CourseAssignment> CourseAssignments { get; set; }
```

## Create the Department entity

Create *Models/Department.cs* with the following code:

```

using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Department
    {
        public int DepartmentID { get; set; }

        [StringLength(50, MinimumLength = 3)]
        public string Name { get; set; }

        [DataType(DataType.Currency)]
        [Column(TypeName = "money")]
        public decimal Budget { get; set; }

        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        [Display(Name = "Start Date")]
        public DateTime StartDate { get; set; }

        public int? InstructorID { get; set; }

        public Instructor Administrator { get; set; }
        public ICollection<Course> Courses { get; set; }
    }
}

```

### The Column attribute

Earlier you used the `Column` attribute to change column name mapping. In the code for the `Department` entity, the `Column` attribute is being used to change SQL data type mapping so that the column will be defined using the SQL Server `money` type in the database:

```

[Column(TypeName="money")]
public decimal Budget { get; set; }

```

Column mapping is generally not required, because the Entity Framework chooses the appropriate SQL Server data type based on the CLR type that you define for the property. The CLR `decimal` type maps to a SQL Server `decimal` type. But in this case you know that the column will be holding currency amounts, and the `money` data type is more appropriate for that.

### Foreign key and navigation properties

The foreign key and navigation properties reflect the following relationships:

A department may or may not have an administrator, and an administrator is always an instructor. Therefore the `InstructorID` property is included as the foreign key to the Instructor entity, and a question mark is added after the `int` type designation to mark the property as nullable. The navigation property is named `Administrator` but holds an Instructor entity:

```
public int? InstructorID { get; set; }
public Instructor Administrator { get; set; }
```

A department may have many courses, so there's a `Courses` navigation property:

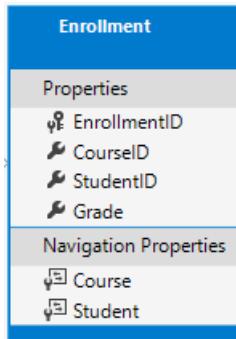

```
public ICollection<Course> Courses { get; set; }
```

#### NOTE

By convention, the Entity Framework enables cascade delete for non-nullable foreign keys and for many-to-many relationships. This can result in circular cascade delete rules, which will cause an exception when you try to add a migration. For example, if you didn't define the `Department.InstructorID` property as nullable, EF would configure a cascade delete rule to delete the instructor when you delete the department, which isn't what you want to have happen. If your business rules required the `InstructorID` property to be non-nullable, you would have to use the following fluent API statement to disable cascade delete on the relationship:

```
modelBuilder.Entity<Department>()
    .HasOne(d => d.Administrator)
    .WithMany()
    .OnDelete(DeleteBehavior.Restrict)
```

## Modify the Enrollment entity

In `Models/Enrollment.cs`, replace the code you added earlier with the following code:

```

using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public enum Grade
    {
        A, B, C, D, F
    }

    public class Enrollment
    {
        public int EnrollmentID { get; set; }
        public int CourseID { get; set; }
        public int StudentID { get; set; }
        [DisplayFormat(NullDisplayText = "No grade")]
        public Grade? Grade { get; set; }

        public Course Course { get; set; }
        public Student Student { get; set; }
    }
}

```

## Foreign key and navigation properties

The foreign key properties and navigation properties reflect the following relationships:

An enrollment record is for a single course, so there's a `CourseID` foreign key property and a `Course` navigation property:

```

public int CourseID { get; set; }
public Course Course { get; set; }

```

An enrollment record is for a single student, so there's a `StudentID` foreign key property and a `Student` navigation property:

```

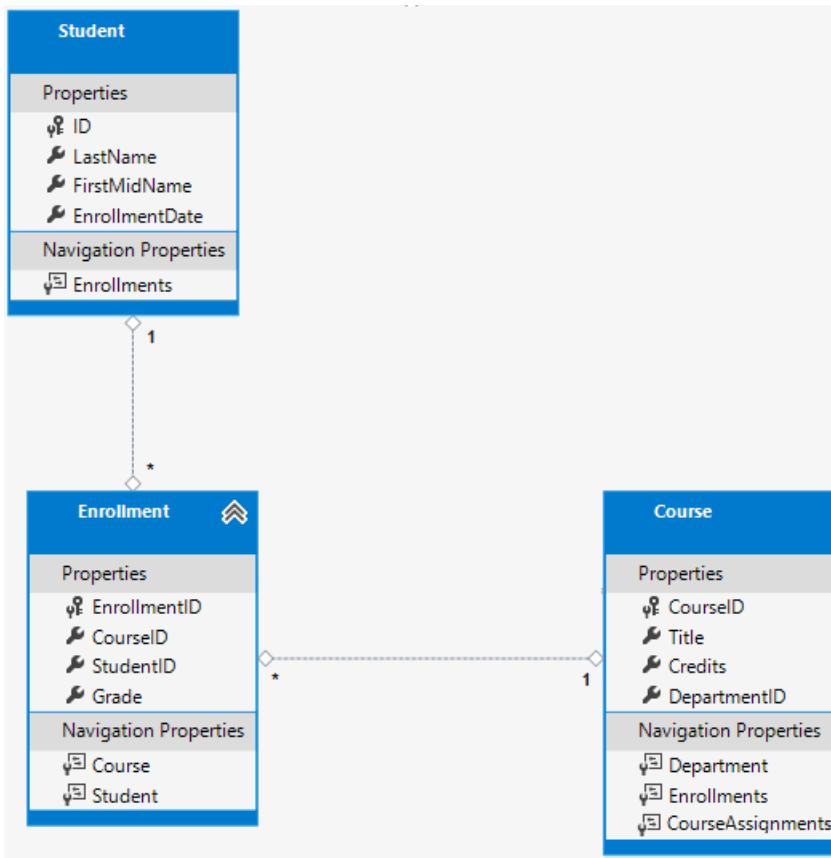

public int StudentID { get; set; }
public Student Student { get; set; }

```

## Many-to-Many Relationships

There's a many-to-many relationship between the `Student` and `Course` entities, and the `Enrollment` entity functions as a many-to-many join table *with payload* in the database. "With payload" means that the `Enrollment` table contains additional data besides foreign keys for the joined tables (in this case, a primary key and a `Grade` property).

The following illustration shows what these relationships look like in an entity diagram. (This diagram was generated using the Entity Framework Power Tools for EF 6.x; creating the diagram isn't part of the tutorial, it's just being used here as an illustration.)

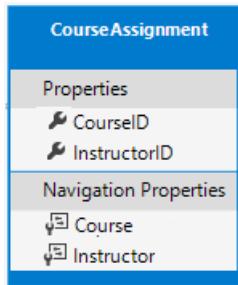

Each relationship line has a 1 at one end and an asterisk (\*) at the other, indicating a one-to-many relationship.

If the Enrollment table didn't include grade information, it would only need to contain the two foreign keys CourseID and StudentID. In that case, it would be a many-to-many join table without payload (or a pure join table) in the database. The Instructor and Course entities have that kind of many-to-many relationship, and your next step is to create an entity class to function as a join table without payload.

(EF 6.x supports implicit join tables for many-to-many relationships, but EF Core doesn't. For more information, see the [discussion in the EF Core GitHub repository](#).)

## The CourseAssignment entity

Create `Models/CourseAssignment.cs` with the following code:

```
using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class CourseAssignment
    {
        public int InstructorID { get; set; }
        public int CourseID { get; set; }
        public Instructor Instructor { get; set; }
        public Course Course { get; set; }
    }
}
```

## Join entity names

A join table is required in the database for the Instructor-to-Courses many-to-many relationship, and it has to be represented by an entity set. It's common to name a join entity `EntityName1EntityName2`, which in this case would be `CourseInstructor`. However, we recommend that you choose a name that describes the relationship. Data models start out simple and grow, with no-payload joins frequently getting payloads later. If you start with a descriptive entity name, you won't have to change the name later. Ideally, the join entity would have its own natural (possibly single word) name in the business domain. For example, Books and Customers could be linked through Ratings. For this relationship, `CourseAssignment` is a better choice than `CourseInstructor`.

## Composite key

Since the foreign keys are not nullable and together uniquely identify each row of the table, there's no need for a separate primary key. The `InstructorID` and `CourseID` properties should function as a composite primary key. The only way to identify composite primary keys to EF is by using the *fluent API* (it can't be done by using attributes). You'll see how to configure the composite primary key in the next section.

The composite key ensures that while you can have multiple rows for one course, and multiple rows for one instructor, you can't have multiple rows for the same instructor and course. The `Enrollment` join entity defines its own primary key, so duplicates of this sort are possible. To prevent such duplicates, you could add a unique index on the foreign key fields, or configure `Enrollment` with a primary composite key similar to `CourseAssignment`. For more information, see [Indexes](#).

## Update the database context

Add the following highlighted code to the `Data/SchoolContext.cs` file:

```

using ContosoUniversity.Models;
using Microsoft.EntityFrameworkCore;

namespace ContosoUniversity.Data
{
    public class SchoolContext : DbContext
    {
        public SchoolContext(DbContextOptions<SchoolContext> options) : base(options)
        {}

        public DbSet<Course> Courses { get; set; }
        public DbSet<Enrollment> Enrollments { get; set; }
        public DbSet<Student> Students { get; set; }
        public DbSet<Department> Departments { get; set; }
        public DbSet<Instructor> Instructors { get; set; }
        public DbSet<OfficeAssignment> OfficeAssignments { get; set; }
        public DbSet<CourseAssignment> CourseAssignments { get; set; }

        protected override void OnModelCreating(ModelBuilder modelBuilder)
        {
            modelBuilder.Entity<Course>().ToTable("Course");
            modelBuilder.Entity<Enrollment>().ToTable("Enrollment");
            modelBuilder.Entity<Student>().ToTable("Student");
            modelBuilder.Entity<Department>().ToTable("Department");
            modelBuilder.Entity<Instructor>().ToTable("Instructor");
            modelBuilder.Entity<OfficeAssignment>().ToTable("OfficeAssignment");
            modelBuilder.Entity<CourseAssignment>().ToTable("CourseAssignment");

            modelBuilder.Entity<CourseAssignment>()
                .HasKey(c => new { c.CourseID, c.InstructorID });
        }
    }
}

```

This code adds the new entities and configures the `CourseAssignment` entity's composite primary key.

## Fluent API alternative to attributes

The code in the `OnModelCreating` method of the `DbContext` class uses the *fluent API* to configure EF behavior. The API is called "fluent" because it's often used by stringing a series of method calls together into a single statement, as in this example from the [EF Core documentation](#):

```

protected override void OnModelCreating(ModelBuilder modelBuilder)
{
    modelBuilder.Entity<Blog>()
        .Property(b => b.Url)
        .IsRequired();
}

```

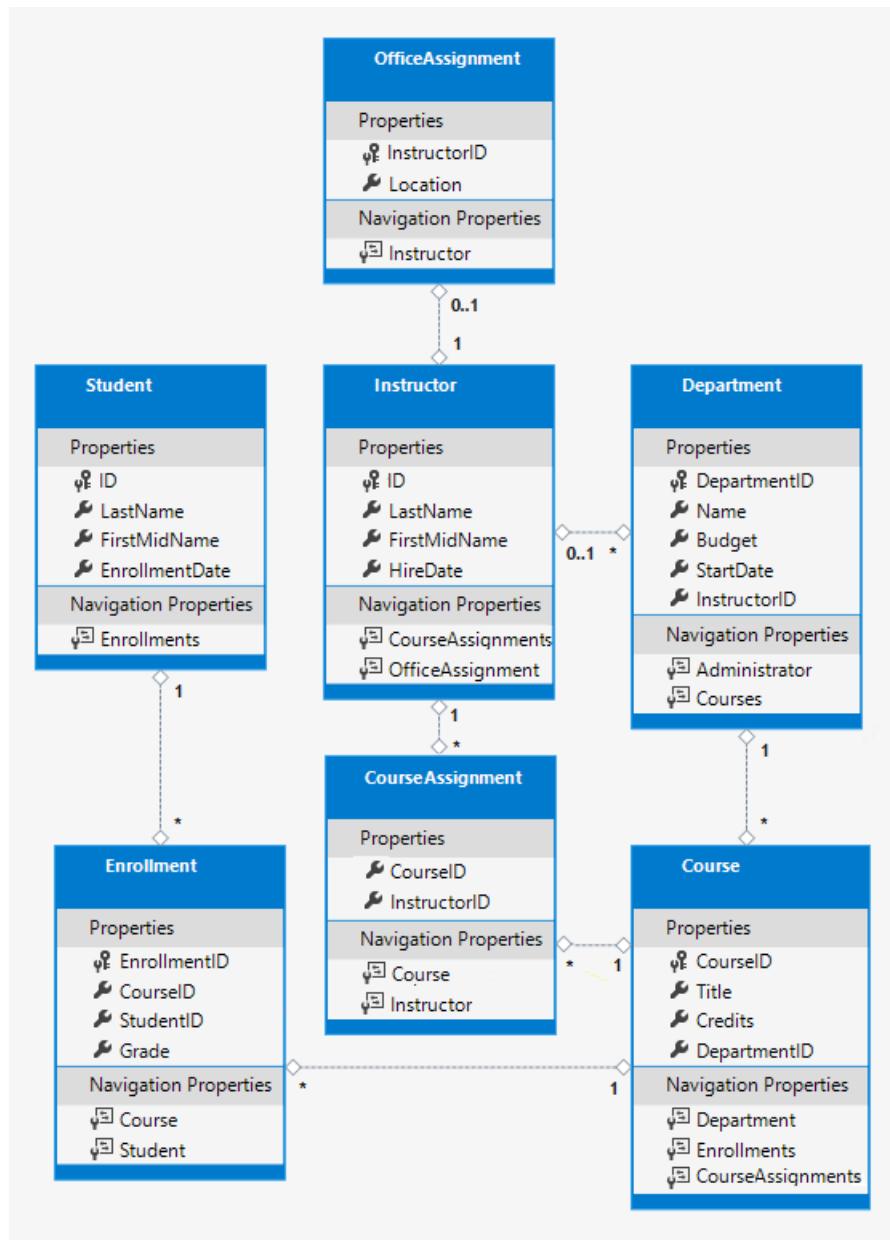

In this tutorial, you're using the fluent API only for database mapping that you can't do with attributes. However, you can also use the fluent API to specify most of the formatting, validation, and mapping rules that you can do by using attributes. Some attributes such as `MinLength` can't be applied with the fluent API. As mentioned previously, `MinLength` doesn't change the schema, it only applies a client and server side validation rule.

Some developers prefer to use the fluent API exclusively so that they can keep their entity classes "clean." You can mix attributes and fluent API if you want, and there are a few customizations that can only be done by using fluent API, but in general the recommended practice is to choose one of these two approaches and use that consistently as much as possible. If you do use both, note that wherever there's a conflict, Fluent API overrides attributes.

For more information about attributes vs. fluent API, see [Methods of configuration](#).

## Entity Diagram Showing Relationships

The following illustration shows the diagram that the Entity Framework Power Tools create for the completed School model.

Besides the one-to-many relationship lines (1 to \*), you can see here the one-to-zero-or-one relationship line (1 to 0..1) between the Instructor and OfficeAssignment entities and the zero-or-one-to-many relationship line (0..1 to \*) between the Instructor and Department entities.

## Seed the Database with Test Data

Replace the code in the *Data/DbInitializer.cs* file with the following code in order to provide seed data for the new entities you've created.

```
using System;
using System.Linq;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using ContosoUniversity.Models;

namespace ContosoUniversity.Data
```

```

    {

        public static class DbInitializer
        {
            public static void Initialize(SchoolContext context)
            {
                //context.Database.EnsureCreated();

                // Look for any students.
                if (context.Students.Any())
                {
                    return; // DB has been seeded
                }

                var students = new Student[]
                {
                    new Student { FirstMidName = "Carson", LastName = "Alexander",
                        EnrollmentDate = DateTime.Parse("2010-09-01") },
                    new Student { FirstMidName = "Meredith", LastName = "Alonso",
                        EnrollmentDate = DateTime.Parse("2012-09-01") },
                    new Student { FirstMidName = "Arturo", LastName = "Anand",
                        EnrollmentDate = DateTime.Parse("2013-09-01") },
                    new Student { FirstMidName = "Gytis", LastName = "Barzdukas",
                        EnrollmentDate = DateTime.Parse("2012-09-01") },
                    new Student { FirstMidName = "Yan", LastName = "Li",
                        EnrollmentDate = DateTime.Parse("2012-09-01") },
                    new Student { FirstMidName = "Peggy", LastName = "Justice",
                        EnrollmentDate = DateTime.Parse("2011-09-01") },
                    new Student { FirstMidName = "Laura", LastName = "Norman",
                        EnrollmentDate = DateTime.Parse("2013-09-01") },
                    new Student { FirstMidName = "Nino", LastName = "Olivetto",
                        EnrollmentDate = DateTime.Parse("2005-09-01") }
                };

                foreach (Student s in students)
                {
                    context.Students.Add(s);
                }
                context.SaveChanges();

                var instructors = new Instructor[]
                {
                    new Instructor { FirstMidName = "Kim", LastName = "Abercrombie",
                        HireDate = DateTime.Parse("1995-03-11") },
                    new Instructor { FirstMidName = "Fadi", LastName = "Fakhouri",
                        HireDate = DateTime.Parse("2002-07-06") },
                    new Instructor { FirstMidName = "Roger", LastName = "Harui",
                        HireDate = DateTime.Parse("1998-07-01") },
                    new Instructor { FirstMidName = "Candace", LastName = "Kapoor",
                        HireDate = DateTime.Parse("2001-01-15") },
                    new Instructor { FirstMidName = "Roger", LastName = "Zheng",
                        HireDate = DateTime.Parse("2004-02-12") }
                };

                foreach (Instructor i in instructors)
                {
                    context.Instructors.Add(i);
                }
                context.SaveChanges();

                var departments = new Department[]
                {
                    new Department { Name = "English", Budget = 350000,
                        StartDate = DateTime.Parse("2007-09-01"),
                        InstructorID = instructors.Single( i => i.LastName == "Abercrombie").ID },
                    new Department { Name = "Mathematics", Budget = 100000,
                        StartDate = DateTime.Parse("2007-09-01"),
                        InstructorID = instructors.Single( i => i.LastName == "Fakhouri").ID },
                    new Department { Name = "Engineering", Budget = 350000,
                        StartDate = DateTime.Parse("2007-09-01") }
                };
            }
        }
    }
}

```

```

        StartDate = DateTime.Parse("2007-09-01"),
        InstructorID = instructors.Single(i => i.LastName == "Harui").ID },
    new Department { Name = "Economics", Budget = 100000,
        StartDate = DateTime.Parse("2007-09-01"),
        InstructorID = instructors.Single(i => i.LastName == "Kapoor").ID }
};

foreach (Department d in departments)
{
    context.Departments.Add(d);
}
context.SaveChanges();

var courses = new Course[]
{
    new Course {CourseID = 1050, Title = "Chemistry", Credits = 3,
        DepartmentID = departments.Single(s => s.Name == "Engineering").DepartmentID
    },
    new Course {CourseID = 4022, Title = "Microeconomics", Credits = 3,

        DepartmentID = departments.Single(s => s.Name == "Mathematics").DepartmentID
    },
    new Course {CourseID = 3141, Title = "Trigonometry", Credits = 4,
        DepartmentID = departments.Single(s => s.Name == "Mathematics").DepartmentID
    },
    new Course {CourseID = 2021, Title = "Composition", Credits = 3,
        DepartmentID = departments.Single(s => s.Name == "English").DepartmentID
    },
    new Course {CourseID = 2042, Title = "Literature", Credits = 4,
        DepartmentID = departments.Single(s => s.Name == "English").DepartmentID
    },
};

foreach (Course c in courses)
{
    context.Courses.Add(c);
}
context.SaveChanges();

var officeAssignments = new OfficeAssignment[]
{
    new OfficeAssignment {
        InstructorID = instructors.Single(i => i.LastName == "Fakhouri").ID,
        Location = "Smith 17"
    },
    new OfficeAssignment {
        InstructorID = instructors.Single(i => i.LastName == "Harui").ID,
        Location = "Gowan 27"
    },
    new OfficeAssignment {
        InstructorID = instructors.Single(i => i.LastName == "Kapoor").ID,
        Location = "Thompson 304"
    }
};

foreach (OfficeAssignment o in officeAssignments)
{
    context.OfficeAssignments.Add(o);
}
context.SaveChanges();

var courseInstructors = new CourseAssignment[]
{
    new CourseAssignment {
        CourseID = courses.Single(c => c.Title == "Chemistry").CourseID,
        InstructorID = instructors.Single(i => i.LastName == "Kapoor").ID
    },
    new CourseAssignment {

```

```

new CourseAssignment {
    CourseID = courses.Single(c => c.Title == "Chemistry" ).CourseID,
    InstructorID = instructors.Single(i => i.LastName == "Harui").ID
},
new CourseAssignment {
    CourseID = courses.Single(c => c.Title == "Microeconomics" ).CourseID,
    InstructorID = instructors.Single(i => i.LastName == "Zheng").ID
},
new CourseAssignment {
    CourseID = courses.Single(c => c.Title == "Macroeconomics" ).CourseID,
    InstructorID = instructors.Single(i => i.LastName == "Zheng").ID
},
new CourseAssignment {
    CourseID = courses.Single(c => c.Title == "Calculus" ).CourseID,
    InstructorID = instructors.Single(i => i.LastName == "Fakhouri").ID
},
new CourseAssignment {
    CourseID = courses.Single(c => c.Title == "Trigonometry" ).CourseID,
    InstructorID = instructors.Single(i => i.LastName == "Harui").ID
},
new CourseAssignment {
    CourseID = courses.Single(c => c.Title == "Composition" ).CourseID,
    InstructorID = instructors.Single(i => i.LastName == "Abercrombie").ID
},
new CourseAssignment {
    CourseID = courses.Single(c => c.Title == "Literature" ).CourseID,
    InstructorID = instructors.Single(i => i.LastName == "Abercrombie").ID
},
};

foreach (CourseAssignment ci in courseInstructors)
{
    context.CourseAssignments.Add(ci);
}
context.SaveChanges();

var enrollments = new Enrollment[]
{
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Alexander").ID,
        CourseID = courses.Single(c => c.Title == "Chemistry" ).CourseID,
        Grade = Grade.A
    },
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Alexander").ID,
        CourseID = courses.Single(c => c.Title == "Microeconomics" ).CourseID,
        Grade = Grade.C
    },
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Alexander").ID,
        CourseID = courses.Single(c => c.Title == "Macroeconomics" ).CourseID,
        Grade = Grade.B
    },
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Alonso").ID,
        CourseID = courses.Single(c => c.Title == "Calculus" ).CourseID,
        Grade = Grade.B
    },
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Alonso").ID,
        CourseID = courses.Single(c => c.Title == "Trigonometry" ).CourseID,
        Grade = Grade.B
    },
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Alonso").ID,
        CourseID = courses.Single(c => c.Title == "Composition" ).CourseID,
        Grade = Grade.B
    },
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Alonso").ID,
        CourseID = courses.Single(c => c.Title == "Composition" ).CourseID,
        Grade = Grade.B
    }
};

```

```

        StudentID = students.Single(s => s.LastName == "Anand").ID,
        CourseID = courses.Single(c => c.Title == "Chemistry" ).CourseID
    },
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Anand").ID,
        CourseID = courses.Single(c => c.Title == "Microeconomics").CourseID,
        Grade = Grade.B
    },
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Barzdukas").ID,
        CourseID = courses.Single(c => c.Title == "Chemistry").CourseID,
        Grade = Grade.B
    },
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Li").ID,
        CourseID = courses.Single(c => c.Title == "Composition").CourseID,
        Grade = Grade.B
    },
    new Enrollment {
        StudentID = students.Single(s => s.LastName == "Justice").ID,
        CourseID = courses.Single(c => c.Title == "Literature").CourseID,
        Grade = Grade.B
    }
}
};

foreach (Enrollment e in enrollments)
{
    var enrollmentInDataBase = context.Enrollments.Where(
        s =>
            s.Student.ID == e.StudentID &&
            s.Course.CourseID == e.CourseID).SingleOrDefault();
    if (enrollmentInDataBase == null)
    {
        context.Enrollments.Add(e);
    }
}
context.SaveChanges();
}
}
}

```

As you saw in the first tutorial, most of this code simply creates new entity objects and loads sample data into properties as required for testing. Notice how the many-to-many relationships are handled: the code creates relationships by creating entities in the `Enrollments` and `courseAssignment` join entity sets.

## Add a migration

Save your changes and build the project. Then open the command window in the project folder and enter the `migrations add` command (don't do the update-database command yet):

```
dotnet ef migrations add ComplexDataModel
```

You get a warning about possible data loss.

An operation was scaffolded that may result in the loss of data. Please review the migration for accuracy.  
Done. To undo this action, use 'ef migrations remove'

If you tried to run the `database update` command at this point (don't do it yet), you would get the following error:

The ALTER TABLE statement conflicted with the FOREIGN KEY constraint "FK\_dbo.Course\_dbo.Department\_DepartmentID". The conflict occurred in database "ContosoUniversity",

```
| table "dbo.Department", column 'DepartmentID'.
```

Sometimes when you execute migrations with existing data, you need to insert stub data into the database to satisfy foreign key constraints. The generated code in the `Up` method adds a non-nullable `DepartmentID` foreign key to the `Course` table. If there are already rows in the `Course` table when the code runs, the `AddColumn` operation fails because SQL Server doesn't know what value to put in the column that can't be null. For this tutorial you'll run the migration on a new database, but in a production application you'd have to make the migration handle existing data, so the following directions show an example of how to do that.

To make this migration work with existing data you have to change the code to give the new column a default value, and create a stub department named "Temp" to act as the default department. As a result, existing `Course` rows will all be related to the "Temp" department after the `Up` method runs.

- Open the `{timestamp}_ComplexDataModel.cs` file.
- Comment out the line of code that adds the `DepartmentID` column to the `Course` table.

```
migrationBuilder.AlterColumn<string>(
    name: "Title",
    table: "Course",
    maxLength: 50,
    nullable: true,
    oldClrType: typeof(string),
    oldNullable: true);

//migrationBuilder.AddColumn<int>(
//    name: "DepartmentID",
//    table: "Course",
//    nullable: false,
//    defaultValue: 0);
```

- Add the following highlighted code after the code that creates the `Department` table:

```

migrationBuilder.CreateTable(
    name: "Department",
    columns: table => new
    {
        DepartmentID = table.Column<int>(nullable: false)
            .Annotation("SqlServer:ValueGenerationStrategy", "IdentityColumn"),
        Budget = table.Column<decimal>(type: "money", nullable: false),
        InstructorID = table.Column<int>(nullable: true),
        Name = table.Column<string>(maxLength: 50, nullable: true),
        StartDate = table.Column<DateTime>(nullable: false)
    },
    constraints: table =>
    {
        table.PrimaryKey("PK_Department", x => x.DepartmentID);
        table.ForeignKey(
            name: "FK_Department_Instructor_InstructorID",
            column: x => x.InstructorID,
            principalTable: "Instructor",
            principalColumn: "ID",
            onDelete: ReferentialAction.Restrict);
    });
}

migrationBuilder.Sql("INSERT INTO dbo.Department (Name, Budget, StartDate) VALUES ('Temp', 0.00, GETDATE());");
// Default value for FK points to department created above, with
// defaultValue changed to 1 in following AddColumn statement.

migrationBuilder.AddColumn<int>(
    name: "DepartmentID",
    table: "Course",
    nullable: false,
    defaultValue: 1);

```

In a production application, you would write code or scripts to add Department rows and relate Course rows to the new Department rows. You would then no longer need the "Temp" department or the default value on the Course.DepartmentID column.

Save your changes and build the project.

## Change the connection string and update the database

You now have new code in the `DbInitializer` class that adds seed data for the new entities to an empty database. To make EF create a new empty database, change the name of the database in the connection string in `appsettings.json` to ContosoUniversity3 or some other name that you haven't used on the computer you're using.

```
{
  "ConnectionStrings": {
    "DefaultConnection": "Server=(localdb)\\mssqllocaldb;Database=ContosoUniversity3;Trusted_Connection=True;MultipleActiveResultSets=true"
  },
}
```

Save your change to `appsettings.json`.

#### NOTE

As an alternative to changing the database name, you can delete the database. Use **SQL Server Object Explorer** (SSOX) or the `database drop` CLI command:

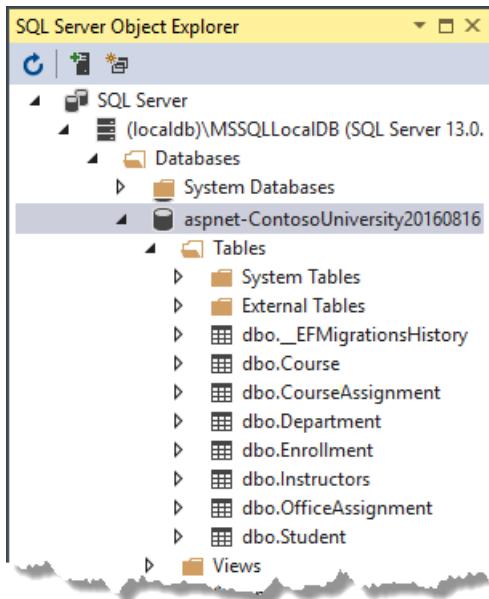

```
dotnet ef database drop
```

After you have changed the database name or deleted the database, run the `database update` command in the command window to execute the migrations.

```
dotnet ef database update
```

Run the app to cause the `DbInitializer.Initialize` method to run and populate the new database.

Open the database in SSOX as you did earlier, and expand the **Tables** node to see that all of the tables have been created. (If you still have SSOX open from the earlier time, click the **Refresh** button.)

Run the app to trigger the initializer code that seeds the database.

Right-click the **CourseAssignment** table and select **View Data** to verify that it has data in it.

	CourseID	InstructorID
▶	2021	1
	2042	1
	1045	2
	1050	3
	3141	3
	1050	4
	4022	5
*	4041	5
*	NULL	NULL

## Summary

You now have a more complex data model and corresponding database. In the following tutorial, you'll learn more about how to access related data.

[PREVIOUS](#) [NEXT](#)

# ASP.NET Core MVC with EF Core - Read Related Data - 6 of 10

7/14/2018 • 15 minutes to read • [Edit Online](#)

This tutorial has not been upgraded to ASP.NET Core 2.1. The ASP.NET Core 2.0 version of this tutorial is available by selecting **ASP.NET Core 2.0** above the table of contents or at the top of the page:

The ASP.NET Core 2.1 Razor Pages version of this tutorial has many improvements over the 2.0 version.

The 2.0 tutorial teaches ASP.NET Core MVC and Entity Framework Core with controllers and views. Razor Pages is a page-based programming model that makes building web UI easier and more productive. We recommend the [Razor Pages](#) tutorial over the MVC version. The Razor Pages tutorial:

- Is easier to follow. For example, the scaffolding code has been significantly simplified.
- Provides more EF Core best practices.
- Uses more efficient queries.
- Is more current with the latest API.
- Covers more features.
- Is the preferred approach for new application development.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub discussion](#).

By [Tom Dykstra](#) and [Rick Anderson](#)

The Contoso University sample web application demonstrates how to create ASP.NET Core MVC web applications using Entity Framework Core and Visual Studio. For information about the tutorial series, see [the first tutorial in the series](#).

In the previous tutorial, you completed the School data model. In this tutorial, you'll read and display related data -- that is, data that the Entity Framework loads into navigation properties.

The following illustrations show the pages that you'll work with.

The screenshot shows a browser window with the title bar "Courses - Contoso Univ". The address bar shows "localhost:5813/Courses". The main content area displays a table titled "Courses" with three rows of data. The columns are "Number", "Title", "Credits", and "Department". The first row contains "1045", "Calculus", "4", and "Mathematics". The second row contains "1050", "Chemistry", "3", and "Engineering". The third row contains "2021", "Composition", "3", and "English". Each row has "Edit | Details | Delete" links in the last column. The browser interface includes standard controls like back, forward, and search, along with a menu icon and a three-dot ellipsis.

Number	Title	Credits	Department	
1045	Calculus	4	Mathematics	Edit   Details   Delete
1050	Chemistry	3	Engineering	Edit   Details   Delete
2021	Composition	3	English	Edit   Details   Delete

## Eager, explicit, and lazy Loading of related data

There are several ways that Object-Relational Mapping (ORM) software such as Entity Framework can load related data into the navigation properties of an entity:

- Eager loading. When the entity is read, related data is retrieved along with it. This typically results in a single join query that retrieves all of the data that's needed. You specify eager loading in Entity Framework Core by using the `Include` and `ThenInclude` methods.

```
var departments = _context.Departments.Include(d => d.Courses);
foreach (Department d in departments)
{
    foreach(Course c in d.Courses)
    {
        courseList.Add(d.Name + c.Title);
    }
}
```

Query: all Departments and related Courses

Query: all Department entities  
and related Course entities

You can retrieve some of the data in separate queries, and EF "fixes up" the navigation properties. That is, EF automatically adds the separately retrieved entities where they belong in navigation properties of previously

retrieved entities. For the query that retrieves related data, you can use the `Load` method instead of a method that returns a list or object, such as `ToList` or `Single`.

```
var departments = _context.Departments;
foreach (Department d in departments)
{
    _context.Courses.Where(c => c.DepartmentID == d.DepartmentID).Load();
    foreach (Course c in d.Courses)
    {
        courseList.Add(d.Name + c.Title);
    }
}
```

Query: all Department rows

Query: Course rows related to Department d

- Explicit loading. When the entity is first read, related data isn't retrieved. You write code that retrieves the related data if it's needed. As in the case of eager loading with separate queries, explicit loading results in multiple queries sent to the database. The difference is that with explicit loading, the code specifies the navigation properties to be loaded. In Entity Framework Core 1.1 you can use the `Load` method to do explicit loading. For example:

```
var departments = _context.Departments;
foreach (Department d in departments)
{
    _context.Entry(d).Collection(p => p.Courses).Load();
    foreach (Course c in d.Courses)
    {
        courseList.Add(d.Name + c.Title);
    }
}
```

Query: all Department rows

Query: Course rows related to Department d

- Lazy loading. When the entity is first read, related data isn't retrieved. However, the first time you attempt to access a navigation property, the data required for that navigation property is automatically retrieved. A query is sent to the database each time you try to get data from a navigation property for the first time. Entity Framework Core 1.0 doesn't support lazy loading.

### Performance considerations

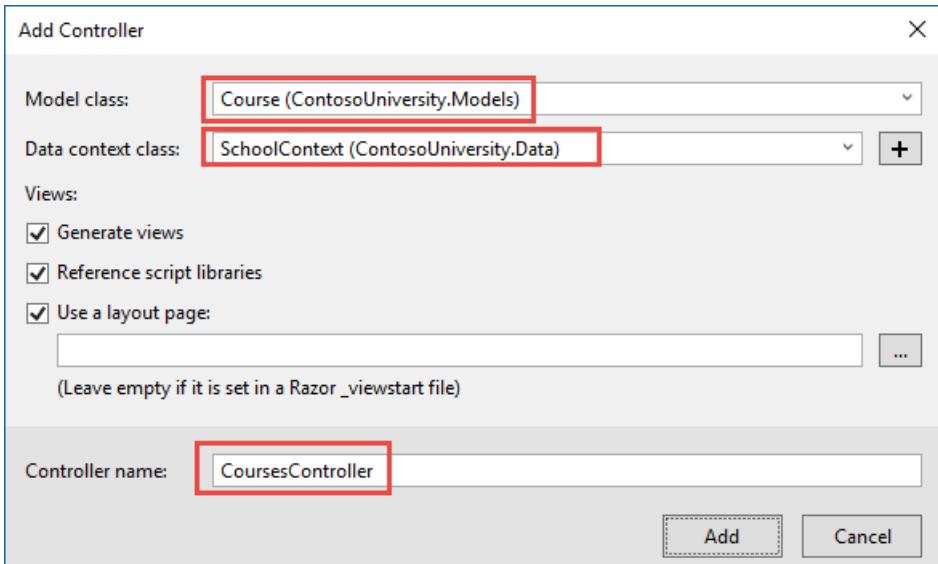

If you know you need related data for every entity retrieved, eager loading often offers the best performance, because a single query sent to the database is typically more efficient than separate queries for each entity retrieved. For example, suppose that each department has ten related courses. Eager loading of all related data would result in just a single (join) query and a single round trip to the database. A separate query for courses for each department would result in eleven round trips to the database. The extra round trips to the database are especially detrimental to performance when latency is high.

On the other hand, in some scenarios separate queries is more efficient. Eager loading of all related data in one query might cause a very complex join to be generated, which SQL Server can't process efficiently. Or if you need to access an entity's navigation properties only for a subset of a set of the entities you're processing, separate queries might perform better because eager loading of everything up front would retrieve more data than you need. If performance is critical, it's best to test performance both ways in order to make the best choice.

## Create a Courses page that displays Department name

The Course entity includes a navigation property that contains the Department entity of the department that the course is assigned to. To display the name of the assigned department in a list of courses, you need to get the `Name` property from the `Department` entity that's in the `Course.Department` navigation property.

Create a controller named `CoursesController` for the `Course` entity type, using the same options for the **MVC Controller with views, using Entity Framework** scaffolder that you did earlier for the `Students` controller, as shown in the following illustration:

Open `CoursesController.cs` and examine the `Index` method. The automatic scaffolding has specified eager loading for the `Department` navigation property by using the `Include` method.

Replace the `Index` method with the following code that uses a more appropriate name for the `IQueryable` that returns `Course` entities (`courses` instead of `schoolContext`):

```
public async Task<IActionResult> Index()
{
    var courses = _context.Courses
        .Include(c => c.Department)
        .AsNoTracking();
    return View(await courses.ToListAsync());
}
```

Open `Views/Courses/Index.cshtml` and replace the template code with the following code. The changes are highlighted:

```

@model IEnumerable<ContosoUniversity.Models.Course>

 @{
     ViewData["Title"] = "Courses";
 }

<h2>Courses</h2>

<p>
    <a asp-action="Create">Create New</a>
</p>
<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.CourseID)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Title)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Credits)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Department)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
        @foreach (var item in Model)
        {
            <tr>
                <td>
                    @Html.DisplayFor(modelItem => item.CourseID)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Title)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Credits)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Department.Name)
                </td>
                <td>
                    <a asp-action="Edit" asp-route-id="@item.CourseID">Edit</a> |
                    <a asp-action="Details" asp-route-id="@item.CourseID">Details</a> |
                    <a asp-action="Delete" asp-route-id="@item.CourseID">Delete</a>
                </td>
            </tr>
        }
    </tbody>
</table>

```

You've made the following changes to the scaffolded code:

- Changed the heading from Index to Courses.
- Added a **Number** column that shows the `CourseID` property value. By default, primary keys aren't scaffolded because normally they're meaningless to end users. However, in this case the primary key is meaningful and you want to show it.
- Changed the **Department** column to display the department name. The code displays the `Name` property of the Department entity that's loaded into the `Department` navigation property:

```
@Html.DisplayFor(modelItem => item.Department.Name)
```

Run the app and select the **Courses** tab to see the list with department names.

Number	Title	Credits	Department	
1045	Calculus	4	Mathematics	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
1050	Chemistry	3	Engineering	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
2021	Composition	3	English	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

## Create an Instructors page that shows Courses and Enrollments

In this section, you'll create a controller and view for the Instructor entity in order to display the Instructors page:

The screenshot shows a web application interface for Contoso University. At the top, there's a header bar with a back/forward button, refresh icon, address bar (localhost:5813/Instructors/Index/1?), and a menu icon.

## Instructors

[Create New](#)

Last Name	First Name	Hire Date	Office	Courses	
Abercrombie	Kim	1995-03-11		2021 Composition 2042 Literature	<a href="#">Select</a>   <a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

Harui	Roger	1998-07-01	Gowan 27	1050 Chemistry 3141 Trigonometry	<a href="#">Select</a>   <a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

## Courses Taught by Selected Instructor

Number	Title	Department
Select 2021	Composition	English
Select 2042	Literature	English

## Students Enrolled in Selected Course

Name	Grade
Alonso, Meredith	B
Li, Yan	B

This page reads and displays related data in the following ways:

- The list of instructors displays related data from the OfficeAssignment entity. The Instructor and OfficeAssignment entities are in a one-to-zero-or-one relationship. You'll use eager loading for the OfficeAssignment entities. As explained earlier, eager loading is typically more efficient when you need the related data for all retrieved rows of the primary table. In this case, you want to display office assignments for all displayed instructors.
- When the user selects an instructor, related Course entities are displayed. The Instructor and Course entities are in a many-to-many relationship. You'll use eager loading for the Course entities and their related Department entities. In this case, separate queries might be more efficient because you need courses only for the selected instructor. However, this example shows how to use eager loading for navigation properties within entities that are themselves in navigation properties.
- When the user selects a course, related data from the Enrollments entity set is displayed. The Course and Enrollment entities are in a one-to-many relationship. You'll use separate queries for Enrollment entities and their related Student entities.

## Create a view model for the Instructor Index view

The Instructors page shows data from three different tables. Therefore, you'll create a view model that includes three properties, each holding the data for one of the tables.

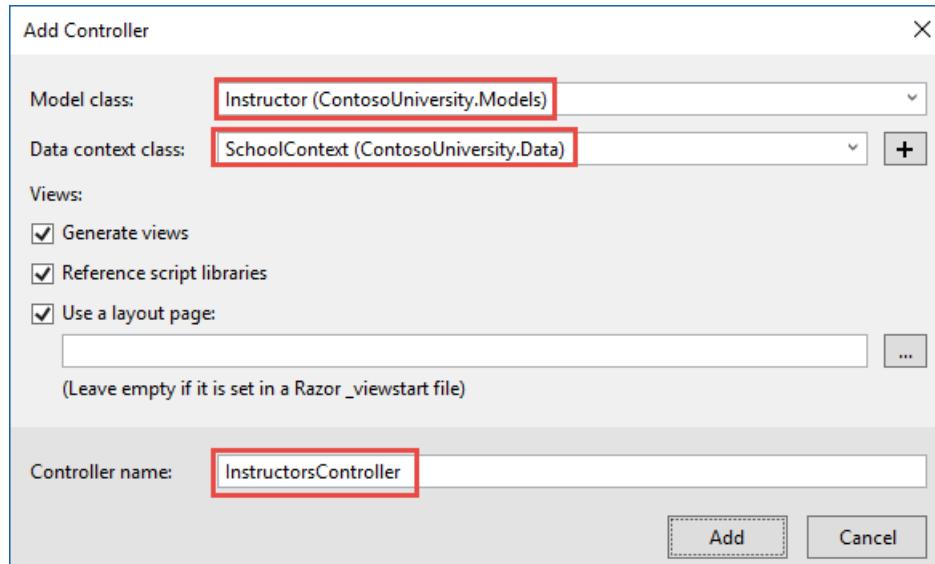

In the *SchoolViewModels* folder, create *InstructorIndexData.cs* and replace the existing code with the following code:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Threading.Tasks;

namespace ContosoUniversity.Models.SchoolViewModels
{
    public class InstructorIndexData
    {
        public IEnumerable<Instructor> Instructors { get; set; }
        public IEnumerable<Course> Courses { get; set; }
        public IEnumerable<Enrollment> Enrollments { get; set; }
    }
}
```

## Create the Instructor controller and views

Create an Instructors controller with EF read/write actions as shown in the following illustration:

Open *InstructorsController.cs* and add a using statement for the *ViewModels* namespace:

```
using ContosoUniversity.Models.SchoolViewModels;
```

Replace the Index method with the following code to do eager loading of related data and put it in the view model.

```

public async Task<IActionResult> Index(int? id, int? courseID)
{
    var viewModel = new InstructorIndexData();
    viewModel.Instructors = await _context.Instructors
        .Include(i => i.OfficeAssignment)
        .Include(i => i.CourseAssignments)
        .ThenInclude(i => i.Course)
        .ThenInclude(i => i.Enrollments)
        .ThenInclude(i => i.Student)
        .Include(i => i.CourseAssignments)
        .ThenInclude(i => i.Course)
        .ThenInclude(i => i.Department)
        .AsNoTracking()
        .OrderBy(i => i.LastName)
        .ToListAsync();

    if (id != null)
    {
        ViewData["InstructorID"] = id.Value;
        Instructor instructor = viewModel.Instructors.Where(
            i => i.ID == id.Value).Single();
        viewModel.Courses = instructor.CourseAssignments.Select(s => s.Course);
    }

    if (courseID != null)
    {
        ViewData["CourseID"] = courseID.Value;
        viewModel.Enrollments = viewModel.Courses.Where(
            x => x.CourseID == courseID).Single().Enrollments;
    }

    return View(viewModel);
}

```

The method accepts optional route data (`id`) and a query string parameter (`courseID`) that provide the ID values of the selected instructor and selected course. The parameters are provided by the **Select** hyperlinks on the page.

The code begins by creating an instance of the view model and putting in it the list of instructors. The code specifies eager loading for the `Instructor.OfficeAssignment` and the `Instructor.CourseAssignments` navigation properties. Within the `CourseAssignments` property, the `Course` property is loaded, and within that, the `Enrollments` and `Department` properties are loaded, and within each `Enrollment` entity the `Student` property is loaded.

```

viewModel.Instructors = await _context.Instructors
    .Include(i => i.OfficeAssignment)
    .Include(i => i.CourseAssignments)
    .ThenInclude(i => i.Course)
    .ThenInclude(i => i.Enrollments)
    .ThenInclude(i => i.Student)
    .Include(i => i.CourseAssignments)
    .ThenInclude(i => i.Course)
    .ThenInclude(i => i.Department)
    .AsNoTracking()
    .OrderBy(i => i.LastName)
    .ToListAsync();

```

Since the view always requires the `OfficeAssignment` entity, it's more efficient to fetch that in the same query. Course entities are required when an instructor is selected in the web page, so a single query is better than multiple queries only if the page is displayed more often with a course selected than without.

The code repeats `CourseAssignments` and `Course` because you need two properties from `Course`. The first string

of `ThenInclude` calls gets `CourseAssignment.Course`, `Course.Enrollments`, and `Enrollment.Student`.

```
viewModel.Instructors = await _context.Instructors
    .Include(i => i.OfficeAssignment)
    .Include(i => i.CourseAssignments)
    .ThenInclude(i => i.Course)
        .ThenInclude(i => i.Enrollments)
            .ThenInclude(i => i.Student)
    .Include(i => i.CourseAssignments)
        .ThenInclude(i => i.Course)
            .ThenInclude(i => i.Department)
    .AsNoTracking()
    .OrderBy(i => i.LastName)
    .ToListAsync();
```

At that point in the code, another `ThenInclude` would be for navigation properties of `Student`, which you don't need. But calling `Include` starts over with `Instructor` properties, so you have to go through the chain again, this time specifying `Course.Department` instead of `Course.Enrollments`.

```
viewModel.Instructors = await _context.Instructors
    .Include(i => i.OfficeAssignment)
    .Include(i => i.CourseAssignments)
    .ThenInclude(i => i.Course)
        .ThenInclude(i => i.Enrollments)
            .ThenInclude(i => i.Student)
    .Include(i => i.CourseAssignments)
        .ThenInclude(i => i.Course)
            .ThenInclude(i => i.Department)
    .AsNoTracking()
    .OrderBy(i => i.LastName)
    .ToListAsync();
```

The following code executes when an instructor was selected. The selected instructor is retrieved from the list of instructors in the view model. The view model's `Courses` property is then loaded with the Course entities from that instructor's `CourseAssignments` navigation property.

```
if (id != null)
{
    ViewData["InstructorID"] = id.Value;
    Instructor instructor = viewModel.Instructors.Where(
        i => i.ID == id.Value).Single();
    viewModel.Courses = instructor.CourseAssignments.Select(s => s.Course);
}
```

The `Where` method returns a collection, but in this case the criteria passed to that method result in only a single Instructor entity being returned. The `Single` method converts the collection into a single Instructor entity, which gives you access to that entity's `CourseAssignments` property. The `CourseAssignments` property contains `CourseAssignment` entities, from which you want only the related `Course` entities.

You use the `Single` method on a collection when you know the collection will have only one item. The `Single` method throws an exception if the collection passed to it's empty or if there's more than one item. An alternative is `SingleOrDefault`, which returns a default value (null in this case) if the collection is empty. However, in this case that would still result in an exception (from trying to find a `Courses` property on a null reference), and the exception message would less clearly indicate the cause of the problem. When you call the `Single` method, you can also pass in the `Where` condition instead of calling the `Where` method separately:

```
.Single(i => i.ID == id.Value)
```

Instead of:

```
.Where(i => i.ID == id.Value).Single()
```

Next, if a course was selected, the selected course is retrieved from the list of courses in the view model. Then the view model's `Enrollments` property is loaded with the Enrollment entities from that course's `Enrollments` navigation property.

```
if (courseID != null)
{
    ViewData["CourseID"] = courseID.Value;
    viewModel.Enrollments = viewModel.Courses.Where(
        x => x.CourseID == courseID).Single().Enrollments;
}
```

### Modify the Instructor Index view

In `Views/Instructors/Index.cshtml`, replace the template code with the following code. The changes are highlighted.

```

@model ContosoUniversity.Models.SchoolViewModels.InstructorIndexData

 @{
     ViewData["Title"] = "Instructors";
 }

<h2>Instructors</h2>

<p>
    <a asp-action="Create">Create New</a>
</p>
<table class="table">
    <thead>
        <tr>
            <th>Last Name</th>
            <th>First Name</th>
            <th>Hire Date</th>
            <th>Office</th>
            <th>Courses</th>
            <th></th>
        </tr>
    </thead>
    <tbody>
        @foreach (var item in Model.Instructors)
        {
            string selectedRow = "";
            if (item.ID == (int?)ViewData["InstructorID"])
            {
                selectedRow = "success";
            }
            <tr class="@selectedRow">
                <td>
                    @Html.DisplayFor(modelItem => item.LastName)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.FirstMidName)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.HireDate)
                </td>
                <td>
                    @if (item.OfficeAssignment != null)
                    {
                        @item.OfficeAssignment.Location
                    }
                </td>
                <td>
                    @{
                        foreach (var course in item.CourseAssignments)
                        {
                            @course.Course.CourseID @: @course.Course.Title <br />
                        }
                    }
                </td>
                <td>
                    <a asp-action="Index" asp-route-id="@item.ID">Select</a> |
                    <a asp-action="Edit" asp-route-id="@item.ID">Edit</a> |
                    <a asp-action="Details" asp-route-id="@item.ID">Details</a> |
                    <a asp-action="Delete" asp-route-id="@item.ID">Delete</a>
                </td>
            </tr>
        }
    </tbody>
</table>

```

You've made the following changes to the existing code:

- Changed the model class to `InstructorIndexData`.
- Changed the page title from **Index** to **Instructors**.
- Added an **Office** column that displays `item.OfficeAssignment.Location` only if `item.OfficeAssignment` isn't null. (Because this is a one-to-zero-or-one relationship, there might not be a related OfficeAssignment entity.)

```
@if (item.OfficeAssignment != null)
{
    item.OfficeAssignment.Location
}
```

- Added a **Courses** column that displays courses taught by each instructor. See [Explicit Line Transition with @:](#) for more about this razor syntax.
- Added code that dynamically adds `class="success"` to the `tr` element of the selected instructor. This sets a background color for the selected row using a Bootstrap class.

```
string selectedRow = "";
if (item.ID == (int?)ViewData["InstructorID"])
{
    selectedRow = "success";
}
<tr class="@selectedRow">
```

- Added a new hyperlink labeled **Select** immediately before the other links in each row, which causes the selected instructor's ID to be sent to the `Index` method.

```
<a asp-action="Index" asp-route-id="@item.ID">Select</a> |
```

Run the app and select the **Instructors** tab. The page displays the Location property of related OfficeAssignment entities and an empty table cell when there's no related OfficeAssignment entity.

Last Name	First Name	Hire Date	Office	Courses
Abercrombie	Kim	1995-03-11		2021 Composition 2042 Literature <a href="#">Select</a>   <a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Fakhouri	Fadi	2002-07-06	Smith 17	1045 Calculus <a href="#">Select</a>   <a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

In the `Views/Instructors/Index.cshtml` file, after the closing table element (at the end of the file), add the following code. This code displays a list of courses related to an instructor when an instructor is selected.

```

@if (Model.Courses != null)
{
    <h3>Courses Taught by Selected Instructor</h3>
    <table class="table">
        <tr>
            <th></th>
            <th>Number</th>
            <th>Title</th>
            <th>Department</th>
        </tr>

        @foreach (var item in Model.Courses)
        {
            string selectedRow = "";
            if (item.CourseID == (int?)ViewData["CourseID"])
            {
                selectedRow = "success";
            }
            <tr class="@selectedRow">
                <td>
                    @Html.ActionLink("Select", "Index", new { courseID = item.CourseID })
                </td>
                <td>
                    @item.CourseID
                </td>
                <td>
                    @item.Title
                </td>
                <td>
                    @item.Department.Name
                </td>
            </tr>
        }
    </table>
}

```

This code reads the `Courses` property of the view model to display a list of courses. It also provides a **Select** hyperlink that sends the ID of the selected course to the `Index` action method.

Refresh the page and select an instructor. Now you see a grid that displays courses assigned to the selected instructor, and for each course you see the name of the assigned department.

Last Name	First Name	Hire Date	Office	Courses
Abercrombie	Kim	1995-03-11	Smith 17	2021 Composition 2042 Literature
Fakhouri	Fadi	2002-07-06		1045 Calculus

## Courses Taught by Selected Instructor

	Number	Title	Department
Select	2021	Composition	English
Select	2042	Literature	English

After the code block you just added, add the following code. This displays a list of the students who are enrolled in a course when that course is selected.

```
@if (Model.Enrollments != null)
{
    <h3>
        Students Enrolled in Selected Course
    </h3>
    <table class="table">
        <tr>
            <th>Name</th>
            <th>Grade</th>
        </tr>
        @foreach (var item in Model.Enrollments)
        {
            <tr>
                <td>
                    @item.Student.FullName
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Grade)
                </td>
            </tr>
        }
    </table>
}
```

This code reads the `Enrollments` property of the view model in order to display a list of students enrolled in the course.

Refresh the page again and select an instructor. Then select a course to see the list of enrolled students and their

grades.

Last Name	First Name	Hire Date	Office	Courses
Abercrombie	Kim	1995-03-11		2021 Composition 2042 Literature <a href="#">Select</a>   <a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

### Courses Taught by Selected Instructor

Number	Title	Department
Select	2021	Composition English
Select	2042	Literature English

### Students Enrolled in Selected Course

Name	Grade
Alonso, Meredith	B
Li, Yan	B

## Explicit loading

When you retrieved the list of instructors in `InstructorsController.cs`, you specified eager loading for the `CourseAssignments` navigation property.

Suppose you expected users to only rarely want to see enrollments in a selected instructor and course. In that case, you might want to load the enrollment data only if it's requested. To see an example of how to do explicit loading, replace the `Index` method with the following code, which removes eager loading for `Enrollments` and loads that property explicitly. The code changes are highlighted.

```

public async Task<IActionResult> Index(int? id, int? courseID)
{
    var viewModel = new InstructorIndexData();
    viewModel.Instructors = await _context.Instructors
        .Include(i => i.OfficeAssignment)
        .Include(i => i.CourseAssignments)
        .ThenInclude(i => i.Course)
        .ThenInclude(i => i.Department)
        .OrderBy(i => i.LastName)
        .ToListAsync();

    if (id != null)
    {
        ViewData["InstructorID"] = id.Value;
        Instructor instructor = viewModel.Instructors.Where(
            i => i.ID == id.Value).Single();
        viewModel.Courses = instructor.CourseAssignments.Select(s => s.Course);
    }

    if (courseID != null)
    {
        ViewData["CourseID"] = courseID.Value;
        var selectedCourse = viewModel.Courses.Where(x => x.CourseID == courseID).Single();
        await _context.Entry(selectedCourse).Collection(x => x.Enrollments).LoadAsync();
        foreach (Enrollment enrollment in selectedCourse.Enrollments)
        {
            await _context.Entry(enrollment).Reference(x => x.Student).LoadAsync();
        }
        viewModel.Enrollments = selectedCourse.Enrollments;
    }

    return View(viewModel);
}

```

The new code drops the `ThenInclude` method calls for enrollment data from the code that retrieves instructor entities. If an instructor and course are selected, the highlighted code retrieves Enrollment entities for the selected course, and Student entities for each Enrollment.

Run the app, go to the Instructors Index page now and you'll see no difference in what's displayed on the page, although you've changed how the data is retrieved.

## Summary

You've now used eager loading with one query and with multiple queries to read related data into navigation properties. In the next tutorial you'll learn how to update related data.

# ASP.NET Core MVC with EF Core - Update Related Data - 7 of 10

6/28/2018 • 19 minutes to read • [Edit Online](#)

This tutorial has not been upgraded to ASP.NET Core 2.1. The ASP.NET Core 2.0 version of this tutorial is available by selecting **ASP.NET Core 2.0** above the table of contents or at the top of the page:

The ASP.NET Core 2.1 Razor Pages version of this tutorial has many improvements over the 2.0 version.

The 2.0 tutorial teaches ASP.NET Core MVC and Entity Framework Core with controllers and views. Razor Pages is a page-based programming model that makes building web UI easier and more productive. We recommend the [Razor Pages](#) tutorial over the MVC version. The Razor Pages tutorial:

- Is easier to follow. For example, the scaffolding code has been significantly simplified.
- Provides more EF Core best practices.
- Uses more efficient queries.
- Is more current with the latest API.
- Covers more features.
- Is the preferred approach for new application development.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub discussion](#).

By [Tom Dykstra](#) and [Rick Anderson](#)

The Contoso University sample web application demonstrates how to create ASP.NET Core MVC web applications using Entity Framework Core and Visual Studio. For information about the tutorial series, see [the first tutorial in the series](#).

In the previous tutorial you displayed related data; in this tutorial you'll update related data by updating foreign key fields and navigation properties.

The following illustrations show some of the pages that you'll work with.

Edit - Coi X + - □ ×

**Credits**

**Department**  
 ▼

The screenshot shows a web browser window titled "Edit - Contoso University". The address bar indicates the URL is "localhost:5813/Instruct". The main content area is titled "Edit" and has a sub-section "Instructor". It contains several input fields: "Last Name" with the value "Abercrombie", "First Name" with the value "Kim", "Hire Date" with the value "3/11/1995", and "Office Location" with the value "44/3P". Below these are several checkboxes for course selection, grouped into three columns. The first column has checkboxes for "1000 Algebra 2" (unchecked) and "2021 Composition" (checked). The second column has checkboxes for "1045 Calculus" (unchecked) and "2042 Literature" (checked). The third column has checkboxes for "1050 Chemistry" (unchecked), "3141 Trigonometry" (unchecked), and "4022 Microeconomics" (unchecked). A "Save" button is located at the bottom left of the form.

## Customize the Create and Edit Pages for Courses

When a new course entity is created, it must have a relationship to an existing department. To facilitate this, the scaffolded code includes controller methods and Create and Edit views that include a drop-down list for selecting the department. The drop-down list sets the `Course.DepartmentID` foreign key property, and that's all the Entity Framework needs in order to load the `Department` navigation property with the appropriate Department entity. You'll use the scaffolded code, but change it slightly to add error handling and sort the drop-down list.

In `CoursesController.cs`, delete the four Create and Edit methods and replace them with the following code:

```
public IActionResult Create()
{
    PopulateDepartmentsDropDownList();
    return View();
}
```

```
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Create([Bind("CourseID,Credits,DepartmentID,Title")] Course course)
{
    if (ModelState.IsValid)
    {
        _context.Add(course);
        await _context.SaveChangesAsync();
        return RedirectToAction(nameof(Index));
    }
    PopulateDepartmentsDropDownList(course.DepartmentID);
    return View(course);
}
```

```
public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var course = await _context.Courses
        .AsNoTracking()
        .SingleOrDefaultAsync(m => m.CourseID == id);
    if (course == null)
    {
        return NotFound();
    }
    PopulateDepartmentsDropDownList(course.DepartmentID);
    return View(course);
}
```

```

[HttpPost, ActionName("Edit")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> EditPost(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var courseToUpdate = await _context.Courses
        .SingleOrDefaultAsync(c => c.CourseID == id);

    if (await TryUpdateModelAsync<Course>(courseToUpdate,
        "",
        c => c.Credits, c => c.DepartmentID, c => c.Title))
    {
        try
        {
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateException /* ex */)
        {
            //Log the error (uncomment ex variable name and write a log.)
            ModelState.AddModelError("", "Unable to save changes. " +
                "Try again, and if the problem persists, " +
                "see your system administrator.");
        }
        return RedirectToAction(nameof(Index));
    }
    PopulateDepartmentsDropDownList(courseToUpdate.DepartmentID);
    return View(courseToUpdate);
}

```

After the `Edit` `HttpPost` method, create a new method that loads department info for the drop-down list.

```

private void PopulateDepartmentsDropDownList(object selectedDepartment = null)
{
    var departmentsQuery = from d in _context.Departments
                           orderby d.Name
                           select d;
    ViewBag.DepartmentID = new SelectList(departmentsQuery.AsNoTracking(), "DepartmentID", "Name",
    selectedDepartment);
}

```

The `PopulateDepartmentsDropDownList` method gets a list of all departments sorted by name, creates a `SelectList` collection for a drop-down list, and passes the collection to the view in `ViewBag`. The method accepts the optional `selectedDepartment` parameter that allows the calling code to specify the item that will be selected when the drop-down list is rendered. The view will pass the name "DepartmentID" to the `<select>` tag helper, and the helper then knows to look in the `ViewBag` object for a `SelectList` named "DepartmentID".

The `HttpGet Create` method calls the `PopulateDepartmentsDropDownList` method without setting the selected item, because for a new course the department isn't established yet:

```

public IActionResult Create()
{
    PopulateDepartmentsDropDownList();
    return View();
}

```

The `HttpGet Edit` method sets the selected item, based on the ID of the department that's already assigned to

the course being edited:

```
public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var course = await _context.Courses
        .AsNoTracking()
        .SingleOrDefaultAsync(m => m.CourseID == id);
    if (course == null)
    {
        return NotFound();
    }
    PopulateDepartmentsDropDownList(course.DepartmentID);
    return View(course);
}
```

The `HttpPost` methods for both `Create` and `Edit` also include code that sets the selected item when they redisplay the page after an error. This ensures that when the page is redisplayed to show the error message, whatever department was selected stays selected.

### Add `.AsNoTracking` to Details and Delete methods

To optimize performance of the Course Details and Delete pages, add `AsNoTracking` calls in the `Details` and `HttpGet Delete` methods.

```
public async Task<IActionResult> Details(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var course = await _context.Courses
        .Include(c => c.Department)
        .AsNoTracking()
        .SingleOrDefaultAsync(m => m.CourseID == id);
    if (course == null)
    {
        return NotFound();
    }

    return View(course);
}
```

```

public async Task<IActionResult> Delete(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var course = await _context.Courses
        .Include(c => c.Department)
        .AsNoTracking()
        .SingleOrDefaultAsync(m => m.CourseID == id);
    if (course == null)
    {
        return NotFound();
    }

    return View(course);
}

```

## Modify the Course views

In *Views/Courses/Create.cshtml*, add a "Select Department" option to the **Department** drop-down list, change the caption from **DepartmentID** to **Department**, and add a validation message.

```

<div class="form-group">
    <label asp-for="Department" class="control-label"></label>
    <select asp-for="DepartmentID" class="form-control" asp-items="ViewBag.DepartmentID">
        <option value="">-- Select Department --</option>
    </select>
    <span asp-validation-for="DepartmentID" class="text-danger" />

```

In *Views/Courses/Edit.cshtml*, make the same change for the Department field that you just did in *Create.cshtml*.

Also in *Views/Courses/Edit.cshtml*, add a course number field before the **Title** field. Because the course number is the primary key, it's displayed, but it can't be changed.

```

<div class="form-group">
    <label asp-for="CourseID" class="control-label"></label>
    <div>@Html.DisplayFor(model => model.CourseID)</div>
</div>

```

There's already a hidden field (`<input type="hidden">`) for the course number in the Edit view. Adding a `<label>` tag helper doesn't eliminate the need for the hidden field because it doesn't cause the course number to be included in the posted data when the user clicks **Save** on the **Edit** page.

In *Views/Courses/Delete.cshtml*, add a course number field at the top and change department ID to department name.

```

@model ContosoUniversity.Models.Course

 @{
     ViewData["Title"] = "Delete";
 }

<h2>Delete</h2>

<h3>Are you sure you want to delete this?</h3>
<div>
    <h4>Course</h4>
    <hr />
    <dl class="dl-horizontal">
        <dt>
            @Html.DisplayNameFor(model => model.CourseID)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.CourseID)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Title)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Title)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Credits)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Credits)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Department)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Department.Name)
        </dd>
    </dl>

    <form asp-action="Delete">
        <div class="form-actions no-color">
            <input type="submit" value="Delete" class="btn btn-default" /> |
            <a asp-action="Index">Back to List</a>
        </div>
    </form>
</div>

```

In *Views/Courses/Details.cshtml*, make the same change that you just did for *Delete.cshtml*.

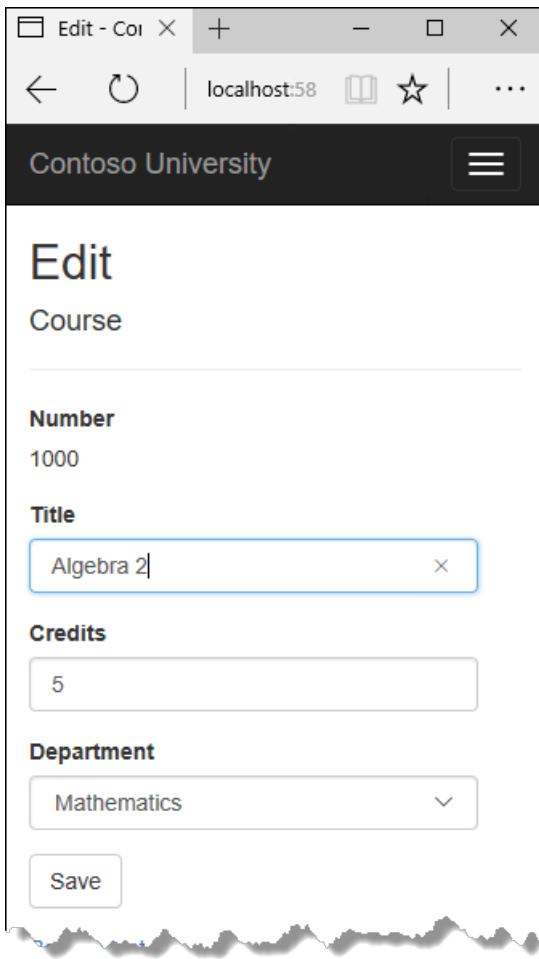

## Test the Course pages

Run the app, select the **Courses** tab, click **Create New**, and enter data for a new course:

The screenshot shows a web browser window with the address bar displaying "localhost:581". The title bar says "Create - C". The main content area is titled "Create" and has a sub-section "Course". It contains four input fields: "Number" with value "1000", "Title" with value "Algebra", "Credits" with value "5", and a dropdown "Department" set to "Mathematics". At the bottom is a "Create" button.

Click **Create**. The Courses Index page is displayed with the new course added to the list. The department name in the Index page list comes from the navigation property, showing that the relationship was established correctly.

Click **Edit** on a course in the Courses Index page.

Change data on the page and click **Save**. The Courses Index page is displayed with the updated course data.

## Add an Edit Page for Instructors

When you edit an instructor record, you want to be able to update the instructor's office assignment. The Instructor entity has a one-to-zero-or-one relationship with the OfficeAssignment entity, which means your code has to handle the following situations:

- If the user clears the office assignment and it originally had a value, delete the OfficeAssignment entity.
- If the user enters an office assignment value and it originally was empty, create a new OfficeAssignment entity.
- If the user changes the value of an office assignment, change the value in an existing OfficeAssignment entity.

### Update the Instructors controller

In *InstructorsController.cs*, change the code in the `HttpGet [Edit]` method so that it loads the Instructor entity's `OfficeAssignment` navigation property and calls `AsNoTracking`:

```

public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var instructor = await _context.Instructors
        .Include(i => i.OfficeAssignment)
        .AsNoTracking()
        .SingleOrDefaultAsync(m => m.ID == id);
    if (instructor == null)
    {
        return NotFound();
    }
    return View(instructor);
}

```

Replace the `HttpPost` `Edit` method with the following code to handle office assignment updates:

```

[HttpPost, ActionName("Edit")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> EditPost(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var instructorToUpdate = await _context.Instructors
        .Include(i => i.OfficeAssignment)
        .SingleOrDefaultAsync(s => s.ID == id);

    if (await TryUpdateModelAsync<Instructor>(
        instructorToUpdate,
        "",
        i => i.FirstMidName, i => i.LastName, i => i.HireDate, i => i.OfficeAssignment))
    {
        if (String.IsNullOrWhiteSpace(instructorToUpdate.OfficeAssignment?.Location))
        {
            instructorToUpdate.OfficeAssignment = null;
        }
        try
        {
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateException /* ex */)
        {
            //Log the error (uncomment ex variable name and write a log.)
            ModelState.AddModelError("", "Unable to save changes. " +
                "Try again, and if the problem persists, " +
                "see your system administrator.");
        }
        return RedirectToAction(nameof(Index));
    }
    return View(instructorToUpdate);
}

```

The code does the following:

- Changes the method name to `EditPost` because the signature is now the same as the `HttpGet` `Edit` method (the `ActionName` attribute specifies that the `/Edit/` URL is still used).
- Gets the current `Instructor` entity from the database using eager loading for the `OfficeAssignment`

navigation property. This is the same as what you did in the `HttpGet` `Edit` method.

- Updates the retrieved Instructor entity with values from the model binder. The `TryUpdateModel` overload enables you to whitelist the properties you want to include. This prevents over-posting, as explained in the [second tutorial](#).

```
if (await TryUpdateModelAsync<Instructor>(
    instructorToUpdate,
    "",
    i => i.FirstMidName, i => i.LastName, i => i.HireDate, i => i.OfficeAssignment))
```

- If the office location is blank, sets the `Instructor.OfficeAssignment` property to null so that the related row in the `OfficeAssignment` table will be deleted.

```
if (String.IsNullOrWhiteSpace(instructorToUpdate.OfficeAssignment?.Location))
{
    instructorToUpdate.OfficeAssignment = null;
}
```

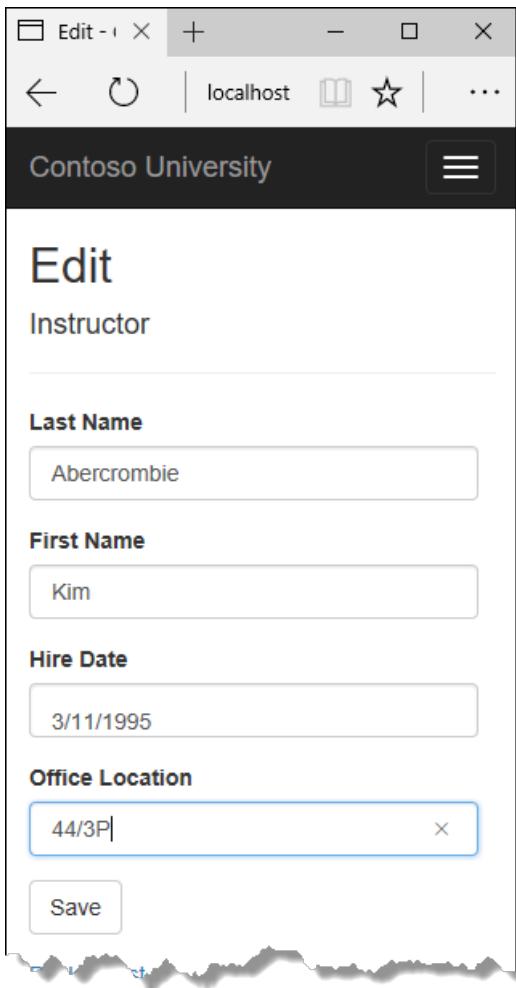

- Saves the changes to the database.

## Update the Instructor Edit view

In `Views/Instructors/Edit.cshtml`, add a new field for editing the office location, at the end before the **Save** button:

```
<div class="form-group">
    <label asp-for="OfficeAssignment.Location" class="control-label"></label>
    <input asp-for="OfficeAssignment.Location" class="form-control" />
    <span asp-validation-for="OfficeAssignment.Location" class="text-danger" />
</div>
```

Run the app, select the **Instructors** tab, and then click **Edit** on an instructor. Change the **Office Location** and click **Save**.

## Add Course assignments to the Instructor Edit page

Instructors may teach any number of courses. Now you'll enhance the Instructor Edit page by adding the ability to change course assignments using a group of check boxes, as shown in the following screen shot:

Last Name  
Abercrombie

First Name  
Kim

Hire Date  
3/11/1995

Office Location  
44/3P

1000 Algebra 2    1045 Calculus    1050 Chemistry  
 2021 Composition    2042 Literature    3141 Trigonometry  
 4022 Microeconomics    4041 Macroeconomics

Save

The relationship between the Course and Instructor entities is many-to-many. To add and remove relationships, you add and remove entities to and from the CourseAssignments join entity set.

The UI that enables you to change which courses an instructor is assigned to is a group of check boxes. A check box for every course in the database is displayed, and the ones that the instructor is currently assigned to are selected. The user can select or clear check boxes to change course assignments. If the number of courses were much greater, you would probably want to use a different method of presenting the data in the view, but you'd use the same method of manipulating a join entity to create or delete relationships.

#### Update the Instructors controller

To provide data to the view for the list of check boxes, you'll use a view model class.

Create *AssignedCourseData.cs* in the *SchoolViewModels* folder and replace the existing code with the following code:

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Threading.Tasks;

namespace ContosoUniversity.Models.SchoolViewModels
{
    public class AssignedCourseData
    {
        public int CourseID { get; set; }
        public string Title { get; set; }
        public bool Assigned { get; set; }
    }
}

```

In *InstructorsController.cs*, replace the `HttpGet` `Edit` method with the following code. The changes are highlighted.

```

public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var instructor = await _context.Instructors
        .Include(i => i.OfficeAssignment)
        .Include(i => i.CourseAssignments).ThenInclude(i => i.Course)
        .AsNoTracking()
        .SingleOrDefaultAsync(m => m.ID == id);
    if (instructor == null)
    {
        return NotFound();
    }
    PopulateAssignedCourseData(instructor);
    return View(instructor);
}

private void PopulateAssignedCourseData(Instructor instructor)
{
    var allCourses = _context.Courses;
    var instructorCourses = new HashSet<int>(instructor.CourseAssignments.Select(c => c.CourseID));
    var viewModel = new List<AssignedCourseData>();
    foreach (var course in allCourses)
    {
        viewModel.Add(new AssignedCourseData
        {
            CourseID = course.CourseID,
            Title = course.Title,
            Assigned = instructorCourses.Contains(course.CourseID)
        });
    }
    ViewData["Courses"] = viewModel;
}

```

The code adds eager loading for the `Courses` navigation property and calls the new `PopulateAssignedCourseData` method to provide information for the check box array using the `AssignedCourseData` view model class.

The code in the `PopulateAssignedCourseData` method reads through all Course entities in order to load a list of courses using the view model class. For each course, the code checks whether the course exists in the instructor's `Courses` navigation property. To create efficient lookup when checking whether a course is assigned to the instructor, the courses assigned to the instructor are put into a `HashSet` collection. The `Assigned` property is set to

true for courses the instructor is assigned to. The view will use this property to determine which check boxes must be displayed as selected. Finally, the list is passed to the view in `ViewData`.

Next, add the code that's executed when the user clicks **Save**. Replace the `EditPost` method with the following code, and add a new method that updates the `Courses` navigation property of the `Instructor` entity.

```
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int? id, string[] selectedCourses)
{
    if (id == null)
    {
        return NotFound();
    }

    var instructorToUpdate = await _context.Instructors
        .Include(i => i.OfficeAssignment)
        .Include(i => i.CourseAssignments)
            .ThenInclude(i => i.Course)
        .SingleOrDefaultAsync(m => m.ID == id);

    if (await TryUpdateModelAsync<Instructor>(
        instructorToUpdate,
        "",
        i => i.FirstMidName, i => i.LastName, i => i.HireDate, i => i.OfficeAssignment))
    {
        if (String.IsNullOrWhiteSpace(instructorToUpdate.OfficeAssignment?.Location))
        {
            instructorToUpdate.OfficeAssignment = null;
        }
        UpdateInstructorCourses(selectedCourses, instructorToUpdate);
        try
        {
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateException /* ex */)
        {
            //Log the error (uncomment ex variable name and write a log.)
            ModelState.AddModelError("", "Unable to save changes. " +
                "Try again, and if the problem persists, " +
                "see your system administrator.");
        }
        return RedirectToAction(nameof(Index));
    }
    UpdateInstructorCourses(selectedCourses, instructorToUpdate);
    PopulateAssignedCourseData(instructorToUpdate);
    return View(instructorToUpdate);
}
```

```

private void UpdateInstructorCourses(string[] selectedCourses, Instructor instructorToUpdate)
{
    if (selectedCourses == null)
    {
        instructorToUpdate.CourseAssignments = new List<CourseAssignment>();
        return;
    }

    var selectedCoursesHS = new HashSet<string>(selectedCourses);
    var instructorCourses = new HashSet<int>
        (instructorToUpdate.CourseAssignments.Select(c => c.Course.CourseID));
    foreach (var course in _context.Courses)
    {
        if (selectedCoursesHS.Contains(course.CourseID.ToString()))
        {
            if (!instructorCourses.Contains(course.CourseID))
            {
                instructorToUpdate.CourseAssignments.Add(new CourseAssignment { InstructorID =
instructorToUpdate.ID, CourseID = course.CourseID });
            }
        }
        else
        {

            if (instructorCourses.Contains(course.CourseID))
            {
                CourseAssignment courseToRemove = instructorToUpdate.CourseAssignments.SingleOrDefault(i =>
i.CourseID == course.CourseID);
                _context.Remove(courseToRemove);
            }
        }
    }
}

```

The method signature is now different from the `HttpGet` `Edit` method, so the method name changes from `EditPost` back to `Edit`.

Since the view doesn't have a collection of `Course` entities, the model binder can't automatically update the `CourseAssignments` navigation property. Instead of using the model binder to update the `CourseAssignments` navigation property, you do that in the new `UpdateInstructorCourses` method. Therefore you need to exclude the `CourseAssignments` property from model binding. This doesn't require any change to the code that calls `TryUpdateModel` because you're using the whitelisting overload and `CourseAssignments` isn't in the include list.

If no check boxes were selected, the code in `UpdateInstructorCourses` initializes the `CourseAssignments` navigation property with an empty collection and returns:

```

private void UpdateInstructorCourses(string[] selectedCourses, Instructor instructorToUpdate)
{
    if (selectedCourses == null)
    {
        instructorToUpdate.CourseAssignments = new List<CourseAssignment>();
        return;
    }

    var selectedCoursesHS = new HashSet<string>(selectedCourses);
    var instructorCourses = new HashSet<int>
        (instructorToUpdate.CourseAssignments.Select(c => c.Course.CourseID));
    foreach (var course in _context.Courses)
    {
        if (selectedCoursesHS.Contains(course.CourseID.ToString()))
        {
            if (!instructorCourses.Contains(course.CourseID))
            {
                instructorToUpdate.CourseAssignments.Add(new CourseAssignment { InstructorID =
instructorToUpdate.ID, CourseID = course.CourseID });
            }
        }
        else
        {

            if (instructorCourses.Contains(course.CourseID))
            {
                CourseAssignment courseToRemove = instructorToUpdate.CourseAssignments.SingleOrDefault(i =>
i.CourseID == course.CourseID);
                _context.Remove(courseToRemove);
            }
        }
    }
}

```

The code then loops through all courses in the database and checks each course against the ones currently assigned to the instructor versus the ones that were selected in the view. To facilitate efficient lookups, the latter two collections are stored in `HashSet` objects.

If the check box for a course was selected but the course isn't in the `Instructor.CourseAssignments` navigation property, the course is added to the collection in the navigation property.

```

private void UpdateInstructorCourses(string[] selectedCourses, Instructor instructorToUpdate)
{
    if (selectedCourses == null)
    {
        instructorToUpdate.CourseAssignments = new List<CourseAssignment>();
        return;
    }

    var selectedCoursesHS = new HashSet<string>(selectedCourses);
    var instructorCourses = new HashSet<int>
        (instructorToUpdate.CourseAssignments.Select(c => c.Course.CourseID));
    foreach (var course in _context.Courses)
    {
        if (selectedCoursesHS.Contains(course.CourseID.ToString()))
        {
            if (!instructorCourses.Contains(course.CourseID))
            {
                instructorToUpdate.CourseAssignments.Add(new CourseAssignment { InstructorID =
instructorToUpdate.ID, CourseID = course.CourseID });
            }
        }
        else
        {

            if (instructorCourses.Contains(course.CourseID))
            {
                CourseAssignment courseToRemove = instructorToUpdate.CourseAssignments.SingleOrDefault(i =>
i.CourseID == course.CourseID);
                _context.Remove(courseToRemove);
            }
        }
    }
}

```

If the check box for a course wasn't selected, but the course is in the `Instructor.CourseAssignments` navigation property, the course is removed from the navigation property.

```

private void UpdateInstructorCourses(string[] selectedCourses, Instructor instructorToUpdate)
{
    if (selectedCourses == null)
    {
        instructorToUpdate.CourseAssignments = new List<CourseAssignment>();
        return;
    }

    var selectedCoursesHS = new HashSet<string>(selectedCourses);
    var instructorCourses = new HashSet<int>
        (instructorToUpdate.CourseAssignments.Select(c => c.Course.CourseID));
    foreach (var course in _context.Courses)
    {
        if (selectedCoursesHS.Contains(course.CourseID.ToString()))
        {
            if (!instructorCourses.Contains(course.CourseID))
            {
                instructorToUpdate.CourseAssignments.Add(new CourseAssignment { InstructorID =
instructorToUpdate.ID, CourseID = course.CourseID });
            }
        }
        else
        {

            if (instructorCourses.Contains(course.CourseID))
            {
                CourseAssignment courseToRemove = instructorToUpdate.CourseAssignments.SingleOrDefault(i =>
i.CourseID == course.CourseID);
                _context.Remove(courseToRemove);
            }
        }
    }
}

```

## Update the Instructor views

In *Views/Instructors/Edit.cshtml*, add a **Courses** field with an array of check boxes by adding the following code immediately after the `div` elements for the **Office** field and before the `div` element for the **Save** button.

### NOTE

When you paste the code in Visual Studio, line breaks will be changed in a way that breaks the code. Press Ctrl+Z one time to undo the automatic formatting. This will fix the line breaks so that they look like what you see here. The indentation doesn't have to be perfect, but the `@</tr><tr>`, `@:<td>`, `@:</td>`, and `@:</tr>` lines must each be on a single line as shown or you'll get a runtime error. With the block of new code selected, press Tab three times to line up the new code with the existing code. You can check the status of this problem [here](#).

```

<div class="form-group">
    <div class="col-md-offset-2 col-md-10">
        <table>
            <tr>
                @{
                    int cnt = 0;
                    List<ContosoUniversity.Models.SchoolViewModels.AssignedCourseData> courses =
                    ViewBag.Courses;

                    foreach (var course in courses)
                    {
                        if (cnt++ % 3 == 0)
                        {
                            @:</tr><tr>
                        }
                        @:<td>
                            <input type="checkbox"
                                name="selectedCourses"
                                value="@course.CourseID"
                                @(Html.Raw(course.Assigned ? "checked=\"checked\" : "")) />
                                @course.CourseID @: @course.Title
                        @:</td>
                    }
                    @:</tr>
                }
            </table>
        </div>
    </div>

```

This code creates an HTML table that has three columns. In each column is a check box followed by a caption that consists of the course number and title. The check boxes all have the same name ("selectedCourses"), which informs the model binder that they're to be treated as a group. The value attribute of each check box is set to the value of `CourseID`. When the page is posted, the model binder passes an array to the controller that consists of the `CourseID` values for only the check boxes which are selected.

When the check boxes are initially rendered, those that are for courses assigned to the instructor have checked attributes, which selects them (displays them checked).

Run the app, select the **Instructors** tab, and click **Edit** on an instructor to see the **Edit** page.

The screenshot shows a web browser window titled "Edit - Contoso University". The address bar displays "localhost:5813/Instruct". The main content area is titled "Edit Instructor". It contains the following form fields:

- Last Name:** Abercrombie
- First Name:** Kim
- Hire Date:** 3/11/1995
- Office Location:** 44/3P
- Courses:** A list of checkboxes for various courses:
  - 1000 Algebra 2
  - 1045 Calculus
  - 1050 Chemistry
  - 2021 Composition
  - 2042 Literature
  - 3141 Trigonometry
  - 4022 Microeconomics
  - 4041 Macroeconomics
- Save:** A button to save the changes.

Change some course assignments and click Save. The changes you make are reflected on the Index page.

**NOTE**

The approach taken here to edit instructor course data works well when there's a limited number of courses. For collections that are much larger, a different UI and a different updating method would be required.

## Update the Delete page

In *InstructorsController.cs*, delete the `DeleteConfirmed` method and insert the following code in its place.

```

[HttpPost, ActionName("Delete")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> DeleteConfirmed(int id)
{
    Instructor instructor = await _context.Instructors
        .Include(i => i.CourseAssignments)
        .SingleAsync(i => i.ID == id);

    var departments = await _context.Departments
        .Where(d => d.InstructorID == id)
        .ToListAsync();
    departments.ForEach(d => d.InstructorID = null);

    _context.Instructors.Remove(instructor);

    await _context.SaveChangesAsync();
    return RedirectToAction(nameof(Index));
}

```

This code makes the following changes:

- Does eager loading for the `CourseAssignments` navigation property. You have to include this or EF won't know about related `CourseAssignment` entities and won't delete them. To avoid needing to read them here you could configure cascade delete in the database.
- If the instructor to be deleted is assigned as administrator of any departments, removes the instructor assignment from those departments.

## Add office location and courses to the Create page

In `InstructorsController.cs`, delete the `HttpGet` and `HttpPost` `Create` methods, and then add the following code in their place:

```

public IActionResult Create()
{
    var instructor = new Instructor();
    instructor.CourseAssignments = new List<CourseAssignment>();
    PopulateAssignedCourseData(instructor);
    return View();
}

// POST: Instructors/Create
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Create([Bind("FirstMidName,HireDate,LastName,OfficeAssignment")] Instructor
instructor, string[] selectedCourses)
{
    if (selectedCourses != null)
    {
        instructor.CourseAssignments = new List<CourseAssignment>();
        foreach (var course in selectedCourses)
        {
            var courseToAdd = new CourseAssignment { InstructorID = instructor.ID, CourseID =
int.Parse(course) };
            instructor.CourseAssignments.Add(courseToAdd);
        }
    }
    if (ModelState.IsValid)
    {
        _context.Add(instructor);
        await _context.SaveChangesAsync();
        return RedirectToAction(nameof(Index));
    }
    PopulateAssignedCourseData(instructor);
    return View(instructor);
}

```

This code is similar to what you saw for the `Edit` methods except that initially no courses are selected. The `HttpGet` `Create` method calls the `PopulateAssignedCourseData` method not because there might be courses selected but in order to provide an empty collection for the `foreach` loop in the view (otherwise the view code would throw a null reference exception).

The `HttpPost` `Create` method adds each selected course to the `CourseAssignments` navigation property before it checks for validation errors and adds the new instructor to the database. Courses are added even if there are model errors so that when there are model errors (for an example, the user keyed an invalid date), and the page is redisplayed with an error message, any course selections that were made are automatically restored.

Notice that in order to be able to add courses to the `CourseAssignments` navigation property you have to initialize the property as an empty collection:

```
instructor.CourseAssignments = new List<CourseAssignment>();
```

As an alternative to doing this in controller code, you could do it in the `Instructor` model by changing the property getter to automatically create the collection if it doesn't exist, as shown in the following example:

```

private ICollection<CourseAssignment> _courseAssignments;
public ICollection<CourseAssignment> CourseAssignments
{
get
{
return _courseAssignments ?? (_courseAssignments = new List<CourseAssignment>());
}
set
{
_courseAssignments = value;
}
}

```

If you modify the `CourseAssignments` property in this way, you can remove the explicit property initialization code in the controller.

In `Views/Instructor/Create.cshtml`, add an office location text box and check boxes for courses before the Submit button. As in the case of the Edit page, [fix the formatting if Visual Studio reformats the code when you paste it](#).

```

<div class="form-group">
    <label asp-for="OfficeAssignment.Location" class="control-label"></label>
    <input asp-for="OfficeAssignment.Location" class="form-control" />
    <span asp-validation-for="OfficeAssignment.Location" class="text-danger" />
</div>

<div class="form-group">
    <div class="col-md-offset-2 col-md-10">
        <table>
            <tr>
                @{
                    int cnt = 0;
                    List<ContosoUniversity.Models.SchoolViewModels.AssignedCourseData> courses =
                    ViewBag.Courses;
                    foreach (var course in courses)
                    {
                        if (cnt++ % 3 == 0)
                        {
                            @:</tr><tr>
                        }
                        @:<td>
                            <input type="checkbox"
                                name="selectedCourses"
                                value="@course.CourseID"
                                @(Html.Raw(course.Assigned ? "checked=\"checked\" : "")) />
                                @course.CourseID @: @course.Title
                        @:</td>
                    }
                    @:</tr>
                }
            </table>
        </div>
    </div>

```

Test by running the app and creating an instructor.

## Handling Transactions

As explained in the [CRUD tutorial](#), the Entity Framework implicitly implements transactions. For scenarios where you need more control -- for example, if you want to include operations done outside of Entity Framework in a transaction -- see [Transactions](#).

## Summary

You have now completed the introduction to working with related data. In the next tutorial you'll see how to handle concurrency conflicts.

# ASP.NET Core MVC with EF Core - Concurrency - 8 of 10

6/28/2018 • 19 minutes to read • [Edit Online](#)

This tutorial has not been upgraded to ASP.NET Core 2.1. The ASP.NET Core 2.0 version of this tutorial is available by selecting **ASP.NET Core 2.0** above the table of contents or at the top of the page:

The ASP.NET Core 2.1 Razor Pages version of this tutorial has many improvements over the 2.0 version.

The 2.0 tutorial teaches ASP.NET Core MVC and Entity Framework Core with controllers and views. Razor Pages is a page-based programming model that makes building web UI easier and more productive. We recommend the [Razor Pages](#) tutorial over the MVC version. The Razor Pages tutorial:

- Is easier to follow. For example, the scaffolding code has been significantly simplified.
- Provides more EF Core best practices.
- Uses more efficient queries.
- Is more current with the latest API.
- Covers more features.
- Is the preferred approach for new application development.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub discussion](#).

By [Tom Dykstra](#) and [Rick Anderson](#)

The Contoso University sample web application demonstrates how to create ASP.NET Core MVC web applications using Entity Framework Core and Visual Studio. For information about the tutorial series, see [the first tutorial in the series](#).

In earlier tutorials, you learned how to update data. This tutorial shows how to handle conflicts when multiple users update the same entity at the same time.

You'll create web pages that work with the Department entity and handle concurrency errors. The following illustrations show the Edit and Delete pages, including some messages that are displayed if a concurrency conflict occurs.

Departmen X Edit - Cont X + - □ ×

localhost:5813/Departr | ⌂ ⌂ ⌂ ...

## Contoso University

# Edit

## Department

---

The record you attempted to edit was modified by another user after you got the original value. The edit operation was canceled and the current values in the database have been displayed. If you still want to edit this record, click the Save button again. Otherwise click the Back to List hyperlink.

**Name**

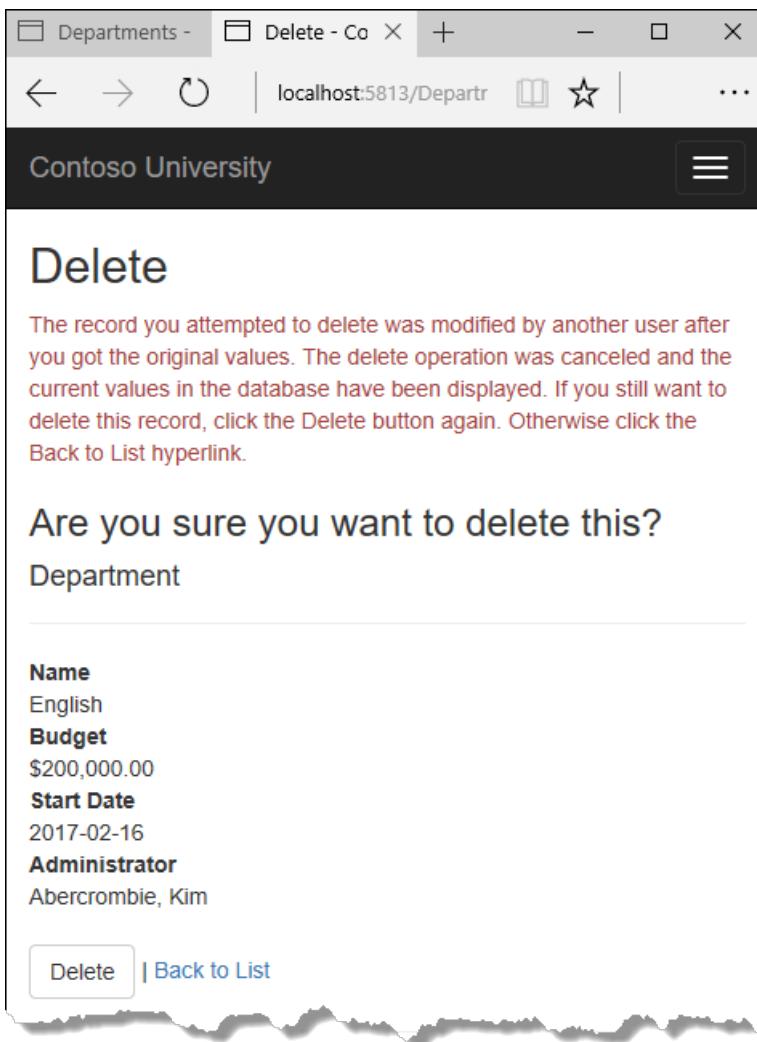

**Budget**

Current value: \$50,000.00

**Start Date**

**InstructorID**

Save

## Concurrency conflicts

A concurrency conflict occurs when one user displays an entity's data in order to edit it, and then another user updates the same entity's data before the first user's change is written to the database. If you don't enable the detection of such conflicts, whoever updates the database last overwrites the other user's changes. In many applications, this risk is acceptable: if there are few users, or few updates, or if isn't really critical if some changes are overwritten, the cost of programming for concurrency might outweigh the benefit. In that case, you don't have to configure the application to handle concurrency conflicts.

### Pessimistic concurrency (locking)

If your application does need to prevent accidental data loss in concurrency scenarios, one way to do that is to use database locks. This is called pessimistic concurrency. For example, before you read a row from a database, you request a lock for read-only or for update access. If you lock a row for update access, no other users are allowed to lock the row either for read-only or update access, because they would get a copy of data that's in the process of being changed. If you lock a row for read-only access, others can also lock it for read-only access but not for update.

Managing locks has disadvantages. It can be complex to program. It requires significant database management resources, and it can cause performance problems as the number of users of an application increases. For these reasons, not all database management systems support pessimistic concurrency. Entity Framework Core provides no built-in support for it, and this tutorial doesn't show you how to implement it.

### Optimistic Concurrency

The alternative to pessimistic concurrency is optimistic concurrency. Optimistic concurrency means allowing concurrency conflicts to happen, and then reacting appropriately if they do. For example, Jane visits the Department Edit page and changes the Budget amount for the English department from \$350,000.00 to \$0.00.

Edit

Department

Budget

Administrator

Name

Start Date

Save

Before Jane clicks **Save**, John visits the same page and changes the Start Date field from 9/1/2007 to 9/1/2013.

Edit

Department

Budget

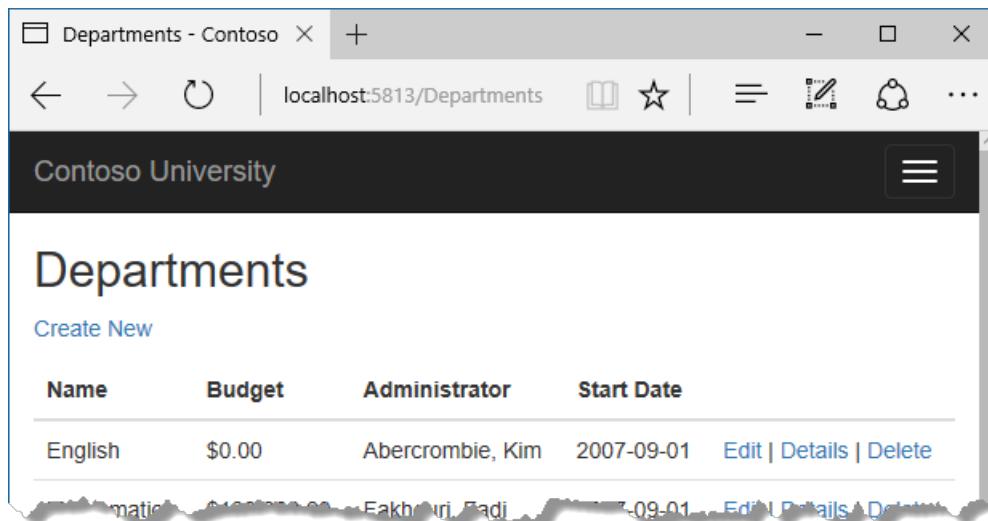

Administrator

Name

Start Date

Save

Jane clicks **Save** first and sees her change when the browser returns to the Index page.

Name	Budget	Administrator	Start Date
English	\$0.00	Abercrombie, Kim	2007-09-01
Information Systems	\$350,000.00	Fakhruji, Fadi	2013-09-01

Then John clicks **Save** on an Edit page that still shows a budget of \$350,000.00. What happens next is determined by how you handle concurrency conflicts.

Some of the options include the following:

- You can keep track of which property a user has modified and update only the corresponding columns in the database.

In the example scenario, no data would be lost, because different properties were updated by the two users. The next time someone browses the English department, they will see both Jane's and John's changes -- a start date of 9/1/2013 and a budget of zero dollars. This method of updating can reduce the number of conflicts that could result in data loss, but it can't avoid data loss if competing changes are made to the same property of an entity. Whether the Entity Framework works this way depends on how you implement your update code. It's often not practical in a web application, because it can require that you maintain large amounts of state in order to keep track of all original property values for an entity as well as new values. Maintaining large amounts of state can affect application performance because it either requires server resources or must be included in the web page itself (for example, in hidden fields) or in a cookie.

- You can let John's change overwrite Jane's change.

The next time someone browses the English department, they will see 9/1/2013 and the restored \$350,000.00 value. This is called a *Client Wins* or *Last in Wins* scenario. (All values from the client take precedence over what's in the data store.) As noted in the introduction to this section, if you don't do any coding for concurrency handling, this will happen automatically.

- You can prevent John's change from being updated in the database.

Typically, you would display an error message, show him the current state of the data, and allow him to reapply his changes if he still wants to make them. This is called a *Store Wins* scenario. (The data-store values take precedence over the values submitted by the client.) You'll implement the Store Wins scenario in this tutorial. This method ensures that no changes are overwritten without a user being alerted to what's happening.

### Detecting concurrency conflicts

You can resolve conflicts by handling `DbConcurrencyException` exceptions that the Entity Framework throws. In order to know when to throw these exceptions, the Entity Framework must be able to detect conflicts. Therefore, you must configure the database and the data model appropriately. Some options for enabling conflict detection include the following:

- In the database table, include a tracking column that can be used to determine when a row has been changed. You can then configure the Entity Framework to include that column in the Where clause of SQL Update or

Delete commands.

The data type of the tracking column is typically `rowversion`. The `rowversion` value is a sequential number that's incremented each time the row is updated. In an Update or Delete command, the Where clause includes the original value of the tracking column (the original row version). If the row being updated has been changed by another user, the value in the `rowversion` column is different than the original value, so the Update or Delete statement can't find the row to update because of the Where clause. When the Entity Framework finds that no rows have been updated by the Update or Delete command (that is, when the number of affected rows is zero), it interprets that as a concurrency conflict.

- Configure the Entity Framework to include the original values of every column in the table in the Where clause of Update and Delete commands.

As in the first option, if anything in the row has changed since the row was first read, the Where clause won't return a row to update, which the Entity Framework interprets as a concurrency conflict. For database tables that have many columns, this approach can result in very large Where clauses, and can require that you maintain large amounts of state. As noted earlier, maintaining large amounts of state can affect application performance. Therefore this approach is generally not recommended, and it isn't the method used in this tutorial.

If you do want to implement this approach to concurrency, you have to mark all non-primary-key properties in the entity you want to track concurrency for by adding the `ConcurrencyCheck` attribute to them. That change enables the Entity Framework to include all columns in the SQL Where clause of Update and Delete statements.

In the remainder of this tutorial you'll add a `rowversion` tracking property to the Department entity, create a controller and views, and test to verify that everything works correctly.

## Add a tracking property to the Department entity

In `Models/Department.cs`, add a tracking property named `RowVersion`:

```

using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Department
    {
        public int DepartmentID { get; set; }

        [StringLength(50, MinimumLength = 3)]
        public string Name { get; set; }

        [DataType(DataType.Currency)]
        [Column(TypeName = "money")]
        public decimal Budget { get; set; }

        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        [Display(Name = "Start Date")]
        public DateTime StartDate { get; set; }

        public int? InstructorID { get; set; }

        [Timestamp]
        public byte[] RowVersion { get; set; }

        public Instructor Administrator { get; set; }
        public ICollection<Course> Courses { get; set; }
    }
}

```

The `Timestamp` attribute specifies that this column will be included in the `Where` clause of `Update` and `Delete` commands sent to the database. The attribute is called `Timestamp` because previous versions of SQL Server used a SQL `timestamp` data type before the SQL `rowversion` replaced it. The .NET type for `rowversion` is a byte array.

If you prefer to use the fluent API, you can use the `IsConcurrencyToken` method (in `Data/SchoolContext.cs`) to specify the tracking property, as shown in the following example:

```

modelBuilder.Entity<Department>()
    .Property(p => p.RowVersion).IsConcurrencyToken();

```

By adding a property you changed the database model, so you need to do another migration.

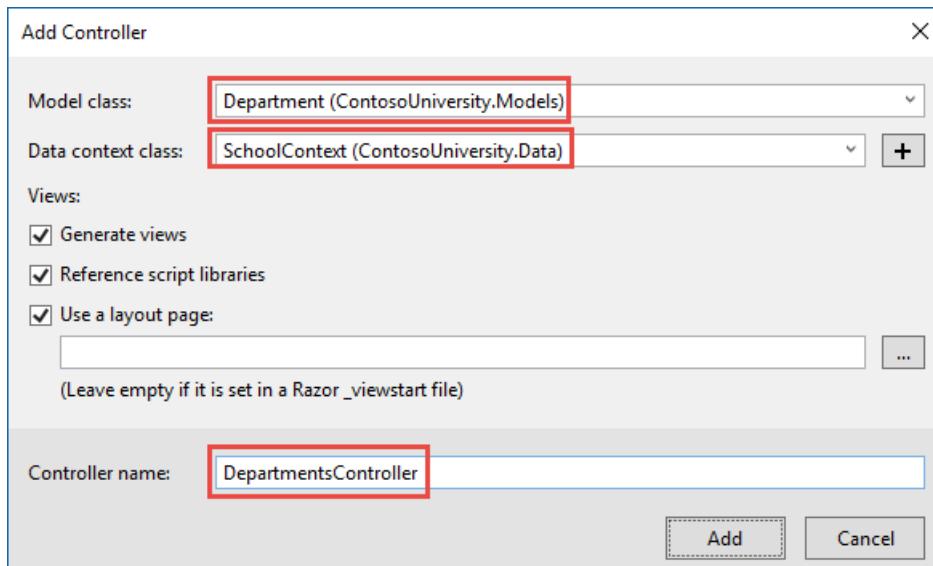

Save your changes and build the project, and then enter the following commands in the command window:

```
dotnet ef migrations add RowVersion
```

```
dotnet ef database update
```

## Create a Departments controller and views

Scaffold a Departments controller and views as you did earlier for Students, Courses, and Instructors.

In the *DepartmentsController.cs* file, change all four occurrences of "FirstMidName" to "FullName" so that the department administrator drop-down lists will contain the full name of the instructor rather than just the last name.

```
ViewData["InstructorID"] = new SelectList(_context.Instructors, "ID", "FullName", department.InstructorID);
```

## Update the Departments Index view

The scaffolding engine created a RowVersion column in the Index view, but that field shouldn't be displayed.

Replace the code in *Views/Departments/Index.cshtml* with the following code.

```

@model IEnumerable<ContosoUniversity.Models.Department>

 @{
     ViewData["Title"] = "Departments";
 }

<h2>Departments</h2>

<p>
    <a asp-action="Create">Create New</a>
</p>
<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.Name)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Budget)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.StartDate)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Administrator)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
        @foreach (var item in Model)
        {
            <tr>
                <td>
                    @Html.DisplayFor(modelItem => item.Name)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Budget)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.StartDate)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Administrator.FullName)
                </td>
                <td>
                    <a asp-action="Edit" asp-route-id="@item.DepartmentID">Edit</a> |
                    <a asp-action="Details" asp-route-id="@item.DepartmentID">Details</a> |
                    <a asp-action="Delete" asp-route-id="@item.DepartmentID">Delete</a>
                </td>
            </tr>
        }
    </tbody>
</table>

```

This changes the heading to "Departments", deletes the RowVersion column, and shows full name instead of first name for the administrator.

## Update the Edit methods in the Departments controller

In both the `HttpGet` `Edit` method and the `Details` method, add `AsNoTracking`. In the `HttpGet` `Edit` method, add eager loading for the Administrator.

```

var department = await _context.Departments
    .Include(i => i.Administrator)
    .AsNoTracking()
    .SingleOrDefaultAsync(m => m.DepartmentID == id);

```

Replace the existing code for the `HttpPost` `Edit` method with the following code:

```

[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int? id, byte[] rowVersion)
{
    if (id == null)
    {
        return NotFound();
    }

    var departmentToUpdate = await _context.Departments.Include(i => i.Administrator).SingleOrDefaultAsync(m => m.DepartmentID == id);

    if (departmentToUpdate == null)
    {
        Department deletedDepartment = new Department();
        await TryUpdateModelAsync(deletedDepartment);
        ModelState.AddModelError(string.Empty,
            "Unable to save changes. The department was deleted by another user.");
        ViewData["InstructorID"] = new SelectList(_context.Instructors, "ID", "FullName",
deletedDepartment.InstructorID);
        return View(deletedDepartment);
    }

    _context.Entry(departmentToUpdate).Property("RowVersion").OriginalValue = rowVersion;

    if (await TryUpdateModelAsync<Department>(
        departmentToUpdate,
        "",
        s => s.Name, s => s.StartDate, s => s.Budget, s => s.InstructorID))
    {
        try
        {
            await _context.SaveChangesAsync();
            return RedirectToAction(nameof(Index));
        }
        catch (DbUpdateConcurrencyException ex)
        {
            var exceptionEntry = ex.Entries.Single();
            var clientValues = (Department)exceptionEntry.Entity;
            var databaseEntry = exceptionEntry.GetDatabaseValues();
            if (databaseEntry == null)
            {
                ModelState.AddModelError(string.Empty,
                    "Unable to save changes. The department was deleted by another user.");
            }
            else
            {
                var databaseValues = (Department)databaseEntry.ToObject();

                if (databaseValues.Name != clientValues.Name)
                {
                    ModelState.AddModelError("Name", $"Current value: {databaseValues.Name}");
                }
                if (databaseValues.Budget != clientValues.Budget)
                {
                    ModelState.AddModelError("Budget", $"Current value: {databaseValues.Budget:c}");
                }
                if (databaseValues.StartDate != clientValues.StartDate)
                {

```

```

        ModelState.AddModelError("StartDate", $"Current value: {databaseValues.StartDate:d}");
    }
    if (databaseValues.InstructorID != clientValues.InstructorID)
    {
        Instructor databaseInstructor = await _context.Instructors.SingleOrDefaultAsync(i => i.ID
== databaseValues.InstructorID);
        ModelState.AddModelError("InstructorID", $"Current value:
{databaseInstructor?.FullName}");
    }

    ModelState.AddModelError(string.Empty, "The record you attempted to edit "
        + "was modified by another user after you got the original value. The "
        + "edit operation was canceled and the current values in the database "
        + "have been displayed. If you still want to edit this record, click "
        + "the Save button again. Otherwise click the Back to List hyperlink.");
departmentToUpdate.RowVersion = (byte[])databaseValues.RowVersion;
ModelState.Remove("RowVersion");
}
}
}
ViewData["InstructorID"] = new SelectList(_context.Instructors, "ID", "FullName",
departmentToUpdate.InstructorID);
return View(departmentToUpdate);
}

```

The code begins by trying to read the department to be updated. If the `SingleOrDefaultAsync` method returns null, the department was deleted by another user. In that case the code uses the posted form values to create a department entity so that the Edit page can be redisplayed with an error message. As an alternative, you wouldn't have to re-create the department entity if you display only an error message without redisplaying the department fields.

The view stores the original `RowVersion` value in a hidden field, and this method receives that value in the `rowVersion` parameter. Before you call `SaveChanges`, you have to put that original `RowVersion` property value in the `OriginalValues` collection for the entity.

```
_context.Entry(departmentToUpdate).Property("RowVersion").OriginalValue = rowVersion;
```

Then when the Entity Framework creates a SQL UPDATE command, that command will include a WHERE clause that looks for a row that has the original `RowVersion` value. If no rows are affected by the UPDATE command (no rows have the original `RowVersion` value), the Entity Framework throws a `DbUpdateConcurrencyException` exception.

The code in the catch block for that exception gets the affected Department entity that has the updated values from the `Entries` property on the exception object.

```
var exceptionEntry = ex.Entries.Single();
```

The `Entries` collection will have just one `EntityEntry` object. You can use that object to get the new values entered by the user and the current database values.

```
var clientValues = (Department)exceptionEntry.Entity;
var databaseEntry = exceptionEntry.GetDatabaseValues();
```

The code adds a custom error message for each column that has database values different from what the user entered on the Edit page (only one field is shown here for brevity).

```
var databaseValues = (Department)databaseEntry.ToObject();

if (databaseValues.Name != clientValues.Name)
{
    ModelState.AddModelError("Name", $"Current value: {databaseValues.Name}");
}
```

Finally, the code sets the `RowVersion` value of the `departmentToUpdate` to the new value retrieved from the database. This new `RowVersion` value will be stored in the hidden field when the Edit page is redisplayed, and the next time the user clicks **Save**, only concurrency errors that happen since the redisplay of the Edit page will be caught.

```
departmentToUpdate.RowVersion = (byte[])databaseValues.RowVersion;
ModelState.Remove("RowVersion");
```

The `ModelState.Remove` statement is required because `ModelState` has the old `RowVersion` value. In the view, the `ModelState` value for a field takes precedence over the model property values when both are present.

## Update the Department Edit view

In `Views/Departments/Edit.cshtml`, make the following changes:

- Add a hidden field to save the `RowVersion` property value, immediately following the hidden field for the `DepartmentID` property.
- Add a "Select Administrator" option to the drop-down list.

```

@model ContosoUniversity.Models.Department

 @{
     ViewData["Title"] = "Edit";
 }

<h2>Edit</h2>

<h4>Department</h4>
<hr />
<div class="row">
    <div class="col-md-4">
        <form asp-action="Edit">
            <div asp-validation-summary="ModelOnly" class="text-danger"></div>
            <input type="hidden" asp-for="DepartmentID" />
            <input type="hidden" asp-for="RowVersion" />
            <div class="form-group">
                <label asp-for="Name" class="control-label"></label>
                <input asp-for="Name" class="form-control" />
                <span asp-validation-for="Name" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Budget" class="control-label"></label>
                <input asp-for="Budget" class="form-control" />
                <span asp-validation-for="Budget" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="StartDate" class="control-label"></label>
                <input asp-for="StartDate" class="form-control" />
                <span asp-validation-for="StartDate" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="InstructorID" class="control-label"></label>
                <select asp-for="InstructorID" class="form-control" asp-items="ViewBag.InstructorID">
                    <option value="">-- Select Administrator --</option>
                </select>
                <span asp-validation-for="InstructorID" class="text-danger"></span>
            </div>
            <div class="form-group">
                <input type="submit" value="Save" class="btn btn-default" />
            </div>
        </form>
    </div>
</div>

<div>
    <a asp-action="Index">Back to List</a>
</div>

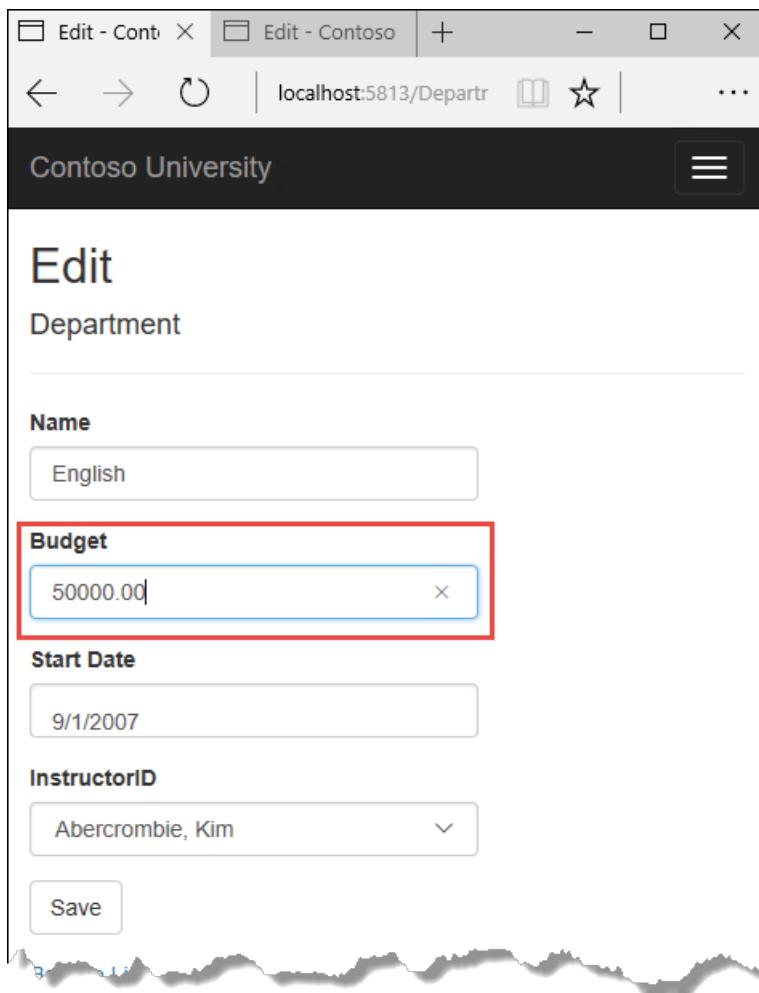

@section Scripts {
    @{await Html.RenderPartialAsync("_ValidationScriptsPartial");}
}

```

## Test concurrency conflicts in the Edit page

Run the app and go to the Departments Index page. Right-click the **Edit** hyperlink for the English department and select **Open in new tab**, then click the **Edit** hyperlink for the English department. The two browser tabs now display the same information.

Change a field in the first browser tab and click **Save**.

The screenshot shows a web browser window with two tabs: "Edit - Contoso" and "Edit - Contoso". The active tab displays the URL "localhost:5813/Departments/1/edit". The page title is "Contoso University". The main content is an "Edit" form for a "Department". The form fields include:

- Name**: English
- Budget**: 50000.00 (This field is highlighted with a red border)
- Start Date**: 9/1/2007
- InstructorID**: Abercrombie, Kim

A "Save" button is located at the bottom left of the form.

The browser shows the Index page with the changed value.

Change a field in the second browser tab.

Departments - Edit - Cont... + - ×

localhost:5813/Departr

Contoso University

Edit

Department

Name

English

Budget

200000.00

Start Date

9/1/2007

InstructorID

Abercrombie, Kim

Save

Click **Save**. You see an error message:

The screenshot shows a browser window with the address bar displaying "localhost:5813/Departm". The main content area is titled "Edit" and "Department". A red warning message is present: "The record you attempted to edit was modified by another user after you got the original value. The edit operation was canceled and the current values in the database have been displayed. If you still want to edit this record, click the Save button again. Otherwise click the Back to List hyperlink." Below the message are four form fields: "Name" with value "English", "Budget" with value "200000.00" and note "Current value: \$50,000.00", "Start Date" with value "9/1/2007", and "InstructorID" with value "Abercrombie, Kim". A "Save" button is at the bottom.

Click **Save** again. The value you entered in the second browser tab is saved. You see the saved values when the Index page appears.

## Update the Delete page

For the Delete page, the Entity Framework detects concurrency conflicts caused by someone else editing the department in a similar manner. When the `HttpGet` `Delete` method displays the confirmation view, the view includes the original `RowVersion` value in a hidden field. That value is then available to the `HttpPost` `Delete` method that's called when the user confirms the deletion. When the Entity Framework creates the SQL DELETE command, it includes a WHERE clause with the original `RowVersion` value. If the command results in zero rows affected (meaning the row was changed after the Delete confirmation page was displayed), a concurrency exception is thrown, and the `HttpGet` `Delete` method is called with an error flag set to true in order to redisplay the confirmation page with an error message. It's also possible that zero rows were affected because the row was deleted by another user, so in that case no error message is displayed.

### Update the Delete methods in the Departments controller

In `DepartmentsController.cs`, replace the `HttpGet` `Delete` method with the following code:

```

public async Task<IActionResult> Delete(int? id, bool? concurrencyError)
{
    if (id == null)
    {
        return NotFound();
    }

    var department = await _context.Departments
        .Include(d => d.Administrator)
        .AsNoTracking()
        .SingleOrDefaultAsync(m => m.DepartmentID == id);
    if (department == null)
    {
        if (concurrencyError.GetValueOrDefault())
        {
            return RedirectToAction(nameof(Index));
        }
        return NotFound();
    }

    if (concurrencyError.GetValueOrDefault())
    {
        ViewData["ConcurrencyErrorMessage"] = "The record you attempted to delete "
            + "was modified by another user after you got the original values. "
            + "The delete operation was canceled and the current values in the "
            + "database have been displayed. If you still want to delete this "
            + "record, click the Delete button again. Otherwise "
            + "click the Back to List hyperlink.";
    }

    return View(department);
}

```

The method accepts an optional parameter that indicates whether the page is being redisplayed after a concurrency error. If this flag is true and the department specified no longer exists, it was deleted by another user. In that case, the code redirects to the Index page. If this flag is true and the Department does exist, it was changed by another user. In that case, the code sends an error message to the view using `ViewData`.

Replace the code in the `HttpPost` `Delete` method (named `DeleteConfirmed`) with the following code:

```

[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Delete(Department department)
{
    try
    {
        if (await _context.Departments.AnyAsync(m => m.DepartmentID == department.DepartmentID))
        {
            _context.Departments.Remove(department);
            await _context.SaveChangesAsync();
        }
        return RedirectToAction(nameof(Index));
    }
    catch (DbUpdateConcurrencyException /* ex */)
    {
        //Log the error (uncomment ex variable name and write a log.)
        return RedirectToAction(nameof(Delete), new { concurrencyError = true, id = department.DepartmentID });
    }
}

```

In the scaffolded code that you just replaced, this method accepted only a record ID:

```
public async Task<IActionResult> DeleteConfirmed(int id)
```

You've changed this parameter to a Department entity instance created by the model binder. This gives EF access to the RowVersion property value in addition to the record key.

```
public async Task<IActionResult> Delete(Department department)
```

You have also changed the action method name from `DeleteConfirmed` to `Delete`. The scaffolded code used the name `DeleteConfirmed` to give the `HttpPost` method a unique signature. (The CLR requires overloaded methods to have different method parameters.) Now that the signatures are unique, you can stick with the MVC convention and use the same name for the `HttpPost` and `HttpGet` delete methods.

If the department is already deleted, the `AnyAsync` method returns false and the application just goes back to the `Index` method.

If a concurrency error is caught, the code redisplays the `Delete` confirmation page and provides a flag that indicates it should display a concurrency error message.

### Update the `Delete` view

In `Views/Departments/Delete.cshtml`, replace the scaffolded code with the following code that adds an error message field and hidden fields for the `DepartmentID` and `RowVersion` properties. The changes are highlighted.

```

@model ContosoUniversity.Models.Department

 @{
     ViewData["Title"] = "Delete";
 }

<h2>Delete</h2>

<p class="text-danger">@ViewData["ConcurrencyErrorMessage"]</p>

<h3>Are you sure you want to delete this?</h3>
<div>
    <h4>Department</h4>
    <hr />
    <dl class="dl-horizontal">
        <dt>
            @Html.DisplayNameFor(model => model.Name)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Name)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Budget)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Budget)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.StartDate)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.StartDate)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Administrator)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Administrator.FullName)
        </dd>
    </dl>

    <form asp-action="Delete">
        <input type="hidden" asp-for="DepartmentID" />
        <input type="hidden" asp-for="RowVersion" />
        <div class="form-actions no-color">
            <input type="submit" value="Delete" class="btn btn-default" /> |
            <a asp-action="Index">Back to List</a>
        </div>
    </form>
</div>

```

This makes the following changes:

- Adds an error message between the `h2` and `h3` headings.
- Replaces `FirstMidName` with `FullName` in the **Administrator** field.
- Removes the `RowVersion` field.
- Adds a hidden field for the `RowVersion` property.

Run the app and go to the Departments Index page. Right-click the **Delete** hyperlink for the English department and select **Open in new tab**, then in the first tab click the **Edit** hyperlink for the English department.

In the first window, change one of the values, and click **Save**:

Edit

Department

Name

English

Budget

200000.00

Start Date

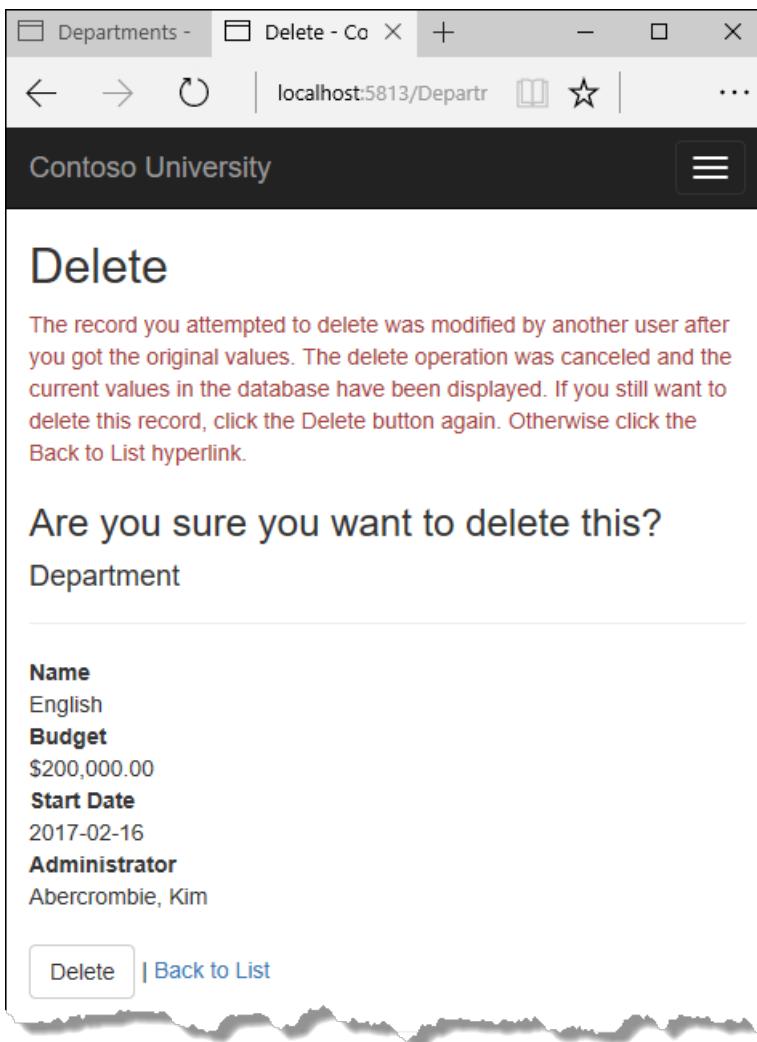

2/16/2017

InstructorID

Abercrombie, Kim

Save

In the second tab, click **Delete**. You see the concurrency error message, and the Department values are refreshed with what's currently in the database.

If you click **Delete** again, you're redirected to the Index page, which shows that the department has been deleted.

## Update Details and Create views

You can optionally clean up scaffolded code in the Details and Create views.

Replace the code in *Views/Departments/Details.cshtml* to delete the RowVersion column and show the full name of the Administrator.

```

@model ContosoUniversity.Models.Department

 @{
     ViewData["Title"] = "Details";
 }

<h2>Details</h2>

<div>
    <h4>Department</h4>
    <hr />
    <dl class="dl-horizontal">
        <dt>
            @Html.DisplayNameFor(model => model.Name)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Name)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Budget)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Budget)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.StartDate)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.StartDate)
        </dd>
        <dt>
            @Html.DisplayNameFor(model => model.Administrator)
        </dt>
        <dd>
            @Html.DisplayFor(model => model.Administrator.FullName)
        </dd>
    </dl>
</div>
<div>
    <a href="#">Edit</a> |
    <a href="#">Back to List</a>
</div>

```

Replace the code in *Views/Departments/Create.cshtml* to add a Select option to the drop-down list.

```

@model ContosoUniversity.Models.Department

 @{
     ViewData["Title"] = "Create";
 }

<h2>Create</h2>

<h4>Department</h4>
<hr />
<div class="row">
    <div class="col-md-4">
        <form asp-action="Create">
            <div asp-validation-summary="ModelOnly" class="text-danger"></div>
            <div class="form-group">
                <label asp-for="Name" class="control-label"></label>
                <input asp-for="Name" class="form-control" />
                <span asp-validation-for="Name" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Budget" class="control-label"></label>
                <input asp-for="Budget" class="form-control" />
                <span asp-validation-for="Budget" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="StartDate" class="control-label"></label>
                <input asp-for="StartDate" class="form-control" />
                <span asp-validation-for="StartDate" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="InstructorID" class="control-label"></label>
                <select asp-for="InstructorID" class="form-control" asp-items="ViewBag.InstructorID">
                    <option value="">-- Select Administrator --</option>
                </select>
            </div>
            <div class="form-group">
                <input type="submit" value="Create" class="btn btn-default" />
            </div>
        </form>
    </div>
</div>

<div>
    <a asp-action="Index">Back to List</a>
</div>

@section Scripts {
    @await Html.RenderPartialAsync("_ValidationScriptsPartial");
}

```

## Summary

This completes the introduction to handling concurrency conflicts. For more information about how to handle concurrency in EF Core, see [Concurrency conflicts](#). The next tutorial shows how to implement table-per-hierarchy inheritance for the Instructor and Student entities.

[NEXT](#)

# ASP.NET Core MVC with EF Core - Inheritance - 9 of 10

6/28/2018 • 8 minutes to read • [Edit Online](#)

This tutorial has not been upgraded to ASP.NET Core 2.1. The ASP.NET Core 2.0 version of this tutorial is available by selecting **ASP.NET Core 2.0** above the table of contents or at the top of the page:

The ASP.NET Core 2.1 Razor Pages version of this tutorial has many improvements over the 2.0 version.

The 2.0 tutorial teaches ASP.NET Core MVC and Entity Framework Core with controllers and views. Razor Pages is a page-based programming model that makes building web UI easier and more productive. We recommend the [Razor Pages](#) tutorial over the MVC version. The Razor Pages tutorial:

- Is easier to follow. For example, the scaffolding code has been significantly simplified.
- Provides more EF Core best practices.
- Uses more efficient queries.
- Is more current with the latest API.
- Covers more features.
- Is the preferred approach for new application development.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub discussion](#).

By [Tom Dykstra](#) and [Rick Anderson](#)

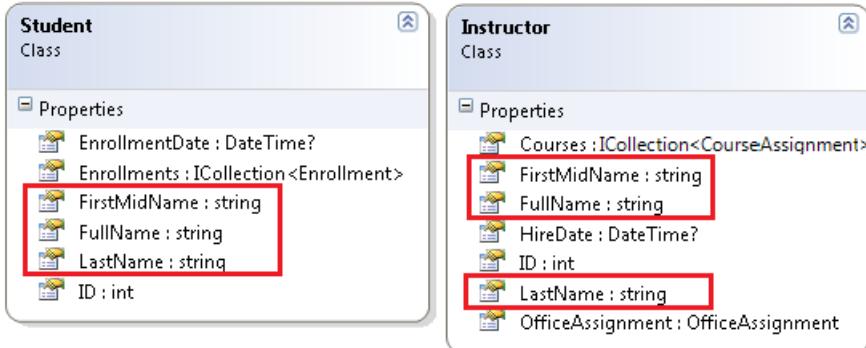

The Contoso University sample web application demonstrates how to create ASP.NET Core MVC web applications using Entity Framework Core and Visual Studio. For information about the tutorial series, see [the first tutorial in the series](#).

In the previous tutorial, you handled concurrency exceptions. This tutorial will show you how to implement inheritance in the data model.

In object-oriented programming, you can use inheritance to facilitate code reuse. In this tutorial, you'll change the `Instructor` and `Student` classes so that they derive from a `Person` base class which contains properties such as `LastName` that are common to both instructors and students. You won't add or change any web pages, but you'll change some of the code and those changes will be automatically reflected in the database.

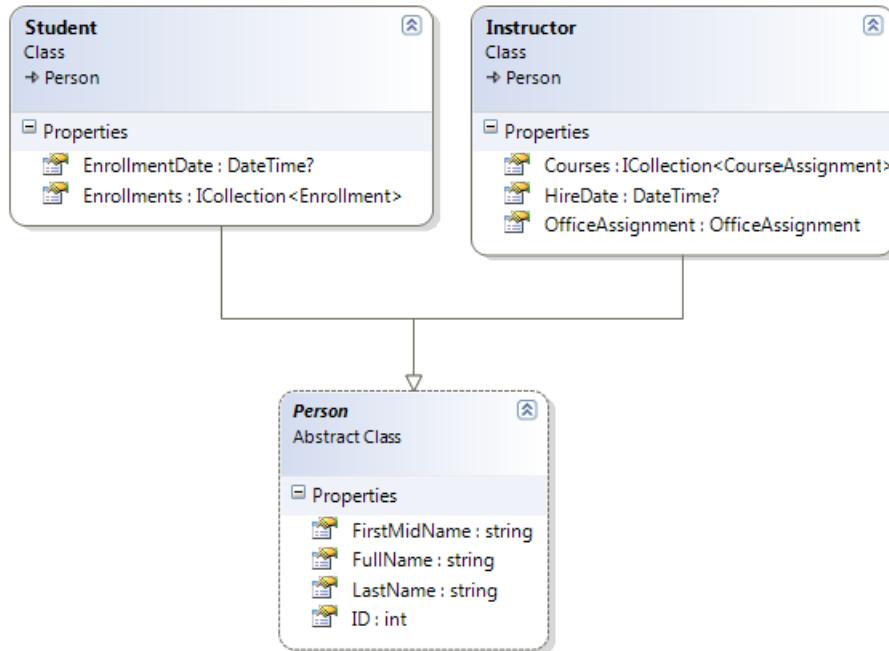

## Options for mapping inheritance to database tables

The `Instructor` and `Student` classes in the School data model have several properties that are identical:

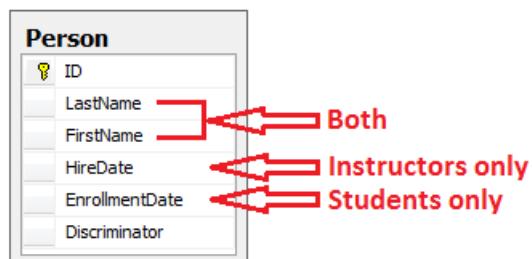

Suppose you want to eliminate the redundant code for the properties that are shared by the `Instructor` and

`Student` entities. Or you want to write a service that can format names without caring whether the name came from an instructor or a student. You could create a `Person` base class that contains only those shared properties, then make the `Instructor` and `Student` classes inherit from that base class, as shown in the following illustration:

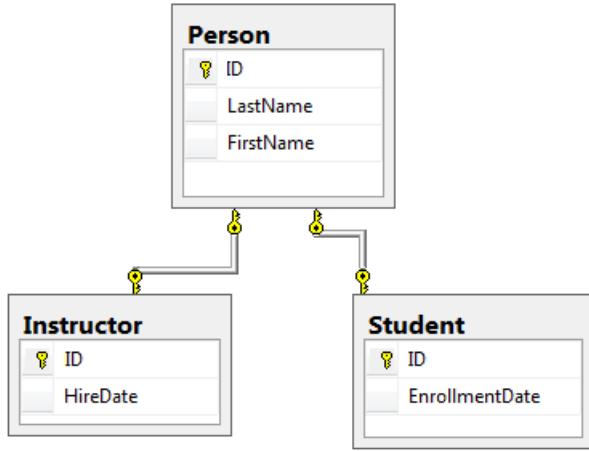

There are several ways this inheritance structure could be represented in the database. You could have a `Person` table that includes information about both students and instructors in a single table. Some of the columns could apply only to instructors (`HireDate`), some only to students (`EnrollmentDate`), some to both (`LastName`, `FirstName`). Typically, you'd have a discriminator column to indicate which type each row represents. For example, the discriminator column might have "Instructor" for instructors and "Student" for students.

This pattern of generating an entity inheritance structure from a single database table is called table-per-hierarchy (TPH) inheritance.

An alternative is to make the database look more like the inheritance structure. For example, you could have only the name fields in the `Person` table and have separate `Instructor` and `Student` tables with the date fields.

This pattern of making a database table for each entity class is called table per type (TPT) inheritance.

Yet another option is to map all non-abstract types to individual tables. All properties of a class, including inherited properties, map to columns of the corresponding table. This pattern is called Table-per-Concrete Class (TPC) inheritance. If you implemented TPC inheritance for the Person, Student, and Instructor classes as shown earlier, the Student and Instructor tables would look no different after implementing inheritance than they did before.

TPC and TPH inheritance patterns generally deliver better performance than TPT inheritance patterns, because TPT patterns can result in complex join queries.

This tutorial demonstrates how to implement TPH inheritance. TPH is the only inheritance pattern that the Entity Framework Core supports. What you'll do is create a `Person` class, change the `Instructor` and `Student` classes to derive from `Person`, add the new class to the `DbContext`, and create a migration.

#### TIP

Consider saving a copy of the project before making the following changes. Then if you run into problems and need to start over, it will be easier to start from the saved project instead of reversing steps done for this tutorial or going back to the beginning of the whole series.

## Create the Person class

In the Models folder, create `Person.cs` and replace the template code with the following code:

```

using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public abstract class Person
    {
        public int ID { get; set; }

        [Required]
        [StringLength(50)]
        [Display(Name = "Last Name")]
        public string LastName { get; set; }

        [Required]
        [StringLength(50, ErrorMessage = "First name cannot be longer than 50 characters.")]
        [Column("FirstName")]
        [Display(Name = "First Name")]
        public string FirstMidName { get; set; }

        [Display(Name = "Full Name")]
        public string FullName
        {
            get
            {
                return LastName + ", " + FirstMidName;
            }
        }
    }
}

```

## Make Student and Instructor classes inherit from Person

In *Instructor.cs*, derive the Instructor class from the Person class and remove the key and name fields. The code will look like the following example:

```

using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Instructor : Person
    {
        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        [Display(Name = "Hire Date")]
        public DateTime HireDate { get; set; }

        public ICollection<CourseAssignment> CourseAssignments { get; set; }
        public OfficeAssignment OfficeAssignment { get; set; }
    }
}

```

Make the same changes in *Student.cs*.

```

using System;
using System.Collections.Generic;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

namespace ContosoUniversity.Models
{
    public class Student : Person
    {
        [DataType(DataType.Date)]
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        [Display(Name = "Enrollment Date")]
        public DateTime EnrollmentDate { get; set; }

        public ICollection<Enrollment> Enrollments { get; set; }
    }
}

```

## Add the Person entity type to the data model

Add the Person entity type to *SchoolContext.cs*. The new lines are highlighted.

```

using ContosoUniversity.Models;
using Microsoft.EntityFrameworkCore;

namespace ContosoUniversity.Data
{
    public class SchoolContext : DbContext
    {
        public SchoolContext(DbContextOptions<SchoolContext> options) : base(options)
        {
        }

        public DbSet<Course> Courses { get; set; }
        public DbSet<Enrollment> Enrollments { get; set; }
        public DbSet<Student> Students { get; set; }
        public DbSet<Department> Departments { get; set; }
        public DbSet<Instructor> Instructors { get; set; }
        public DbSet<OfficeAssignment> OfficeAssignments { get; set; }
        public DbSet<CourseAssignment> CourseAssignments { get; set; }
        public DbSet<Person> People { get; set; }

        protected override void OnModelCreating(ModelBuilder modelBuilder)
        {
            modelBuilder.Entity<Course>().ToTable("Course");
            modelBuilder.Entity<Enrollment>().ToTable("Enrollment");
            modelBuilder.Entity<Student>().ToTable("Student");
            modelBuilder.Entity<Department>().ToTable("Department");
            modelBuilder.Entity<Instructor>().ToTable("Instructor");
            modelBuilder.Entity<OfficeAssignment>().ToTable("OfficeAssignment");
            modelBuilder.Entity<CourseAssignment>().ToTable("CourseAssignment");
            modelBuilder.Entity<Person>().ToTable("Person");

            modelBuilder.Entity<CourseAssignment>()
                .HasKey(c => new { c.CourseID, c.InstructorID });
        }
    }
}

```

This is all that the Entity Framework needs in order to configure table-per-hierarchy inheritance. As you'll see, when the database is updated, it will have a Person table in place of the Student and Instructor tables.

## Create and customize migration code

Save your changes and build the project. Then open the command window in the project folder and enter the following command:

```
dotnet ef migrations add Inheritance
```

Don't run the `database update` command yet. That command will result in lost data because it will drop the Instructor table and rename the Student table to Person. You need to provide custom code to preserve existing data.

Open *Migrations/<timestamp>\_Inheritance.cs* and replace the `Up` method with the following code:

```
protected override void Up(MigrationBuilder migrationBuilder)
{
    migrationBuilder.DropForeignKey(
        name: "FK_Enrollment_Student_StudentID",
        table: "Enrollment");

    migrationBuilder DropIndex(name: "IX_Enrollment_StudentID", table: "Enrollment");

    migrationBuilder.RenameTable(name: "Instructor", newName: "Person");
    migrationBuilder.AddColumn<DateTime>(name: "EnrollmentDate", table: "Person", nullable: true);
    migrationBuilder.AddColumn<string>(name: "Discriminator", table: "Person", nullable: false, maxLength: 128, defaultValue: "Instructor");
    migrationBuilder.AlterColumn<DateTime>(name: "HireDate", table: "Person", nullable: true);
    migrationBuilder.AddColumn<int>(name: "OldId", table: "Person", nullable: true);

    // Copy existing Student data into new Person table.
    migrationBuilder.Sql("INSERT INTO dbo.Person (LastName, FirstName, HireDate, EnrollmentDate, Discriminator, OldId) SELECT LastName, FirstName, null AS HireDate, EnrollmentDate, 'Student' AS Discriminator, ID AS OldId FROM dbo.Student");
    // Fix up existing relationships to match new PK's.
    migrationBuilder.Sql("UPDATE dbo.Enrollment SET StudentId = (SELECT ID FROM dbo.Person WHERE OldId = Enrollment.StudentId AND Discriminator = 'Student')");

    // Remove temporary key
    migrationBuilder.DropColumn(name: "OldID", table: "Person");

    migrationBuilder.DropTable(
        name: "Student");

    migrationBuilder.CreateIndex(
        name: "IX_Enrollment_StudentID",
        table: "Enrollment",
        column: "StudentID");

    migrationBuilder.AddForeignKey(
        name: "FK_Enrollment_Person_StudentID",
        table: "Enrollment",
        column: "StudentID",
        principalTable: "Person",
        principalColumn: "ID",
        onDelete: ReferentialAction.Cascade);
}
```

This code takes care of the following database update tasks:

- Removes foreign key constraints and indexes that point to the Student table.
- Renames the Instructor table as Person and makes changes needed for it to store Student data.
- Adds nullable EnrollmentDate for students.

- Adds Discriminator column to indicate whether a row is for a student or an instructor.
- Makes HireDate nullable since student rows won't have hire dates.
- Adds a temporary field that will be used to update foreign keys that point to students. When you copy students into the Person table they will get new primary key values.
- Copies data from the Student table into the Person table. This causes students to get assigned new primary key values.
- Fixes foreign key values that point to students.
- Re-creates foreign key constraints and indexes, now pointing them to the Person table.

(If you had used GUID instead of integer as the primary key type, the student primary key values wouldn't have to change, and several of these steps could have been omitted.)

Run the `database update` command:

```
dotnet ef database update
```

(In a production system you would make corresponding changes to the `Down` method in case you ever had to use that to go back to the previous database version. For this tutorial you won't be using the `Down` method.)

#### **NOTE**

It's possible to get other errors when making schema changes in a database that has existing data. If you get migration errors that you can't resolve, you can either change the database name in the connection string or delete the database. With a new database, there's no data to migrate, and the `update-database` command is more likely to complete without errors. To delete the database, use SSOX or run the `database drop` CLI command.

## Test with inheritance implemented

Run the app and try various pages. Everything works the same as it did before.

In **SQL Server Object Explorer**, expand **Data Connections/SchoolContext** and then **Tables**, and you see that the Student and Instructor tables have been replaced by a Person table. Open the Person table designer and you see that it has all of the columns that used to be in the Student and Instructor tables.

	Name	Data Type	Allow Nulls	Default
1	ID	int	<input type="checkbox"/>	
2	FirstName	nvarchar(50)	<input type="checkbox"/>	
3	HireDate	datetime2(7)	<input checked="" type="checkbox"/>	
4	LastName	nvarchar(50)	<input type="checkbox"/>	
5	EnrollmentDate	datetime2(7)	<input checked="" type="checkbox"/>	
6	Discriminator	nvarchar(128)	<input type="checkbox"/>	(N'Instructor')

Keys (1)  
PK\_Instructor (Primary Key)

Check Constraints (0)

Indexes (0)

Foreign Keys (0)

Triggers (0)

```
1 CREATE TABLE [dbo].[Person] (
2     [ID] INT IDENTITY (1, 1) NOT NULL,
3     [FirstName] NVARCHAR (50) NOT NULL,
4     [HireDate] DATETIME2 (7) NULL,
5     [LastName] NVARCHAR (50) NOT NULL,
6     [EnrollmentDate] DATETIME2 (7) NULL,
7     [Discriminator] NVARCHAR (128) DEFAULT (N'Instructor') NOT NULL,
8     CONSTRAINT [PK_Instructor] PRIMARY KEY CLUSTERED ([ID] ASC)
9 );
10 
```

100 %

Connection Ready | (localdb)\MSSQLLocalDB | REDMOND\tdykstra | aspnet-ContosoUniversi...

Right-click the Person table, and then click **Show Table Data** to see the discriminator column.

ID	FirstName	HireDate	LastName	Enrollme...	Discriminator
1	Kim	3/11/1995...	Abercrombie	NULL	Instructor
2	Fadi	7/6/2002 ...	Fakhouri	NULL	Instructor
3	Roger	7/1/1998 ...	Harui	NULL	Instructor
4	Candace	1/15/2001...	Kapoor	NULL	Instructor
5	Roger	2/12/2004...	Zheng	NULL	Instructor
7	Nancy	8/17/2016...	Davolio	NULL	Instructor
8	Carson	NULL	Alexander	9/1/2010 ...	Student
9	Meredith	NULL	Alonso	9/1/2012 ...	Student
10	Arturo	NULL	Anand	9/1/2013 ...	Student
11	Gytis	NULL	Barzdukas	9/1/2012 ...	Student
12	Yan	NULL	Li	9/1/2012	Student

## Summary

You've implemented table-per-hierarchy inheritance for the `Person`, `Student`, and `Instructor` classes. For more information about inheritance in Entity Framework Core, see [Inheritance](#). In the next tutorial you'll see how to handle a variety of relatively advanced Entity Framework scenarios.

# ASP.NET Core MVC with EF Core - Advanced - 10 of 10

6/28/2018 • 13 minutes to read • [Edit Online](#)

This tutorial has not been upgraded to ASP.NET Core 2.1. The ASP.NET Core 2.0 version of this tutorial is available by selecting **ASP.NET Core 2.0** above the table of contents or at the top of the page:

The ASP.NET Core 2.1 Razor Pages version of this tutorial has many improvements over the 2.0 version.

The 2.0 tutorial teaches ASP.NET Core MVC and Entity Framework Core with controllers and views. Razor Pages is a page-based programming model that makes building web UI easier and more productive. We recommend the [Razor Pages](#) tutorial over the MVC version. The Razor Pages tutorial:

- Is easier to follow. For example, the scaffolding code has been significantly simplified.
- Provides more EF Core best practices.
- Uses more efficient queries.
- Is more current with the latest API.
- Covers more features.
- Is the preferred approach for new application development.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub discussion](#).

By [Tom Dykstra](#) and [Rick Anderson](#)

The Contoso University sample web application demonstrates how to create ASP.NET Core MVC web applications using Entity Framework Core and Visual Studio. For information about the tutorial series, see [the first tutorial in the series](#).

In the previous tutorial, you implemented table-per-hierarchy inheritance. This tutorial introduces several topics that are useful to be aware of when you go beyond the basics of developing ASP.NET Core web applications that use Entity Framework Core.

## Raw SQL Queries

One of the advantages of using the Entity Framework is that it avoids tying your code too closely to a particular method of storing data. It does this by generating SQL queries and commands for you, which also frees you from having to write them yourself. But there are exceptional scenarios when you need to run specific SQL queries that you have manually created. For these scenarios, the Entity Framework Code First API includes methods that enable you to pass SQL commands directly to the database. You have the following options in EF Core 1.0:

- Use the `DbSet.FromSql` method for queries that return entity types. The returned objects must be of the type expected by the `DbSet` object, and they're automatically tracked by the database context unless you [turn tracking off](#).
- Use the `Database.ExecuteSqlCommand` for non-query commands.

If you need to run a query that returns types that aren't entities, you can use ADO.NET with the database connection provided by EF. The returned data isn't tracked by the database context, even if you use this method to retrieve entity types.

As is always true when you execute SQL commands in a web application, you must take precautions to protect your site against SQL injection attacks. One way to do that is to use parameterized queries to make sure that

strings submitted by a web page can't be interpreted as SQL commands. In this tutorial you'll use parameterized queries when integrating user input into a query.

## Call a query that returns entities

The `DbSet< TEntity >` class provides a method that you can use to execute a query that returns an entity of type `TEntity`. To see how this works you'll change the code in the `Details` method of the Department controller.

In `DepartmentsController.cs`, in the `Details` method, replace the code that retrieves a department with a `FromSql` method call, as shown in the following highlighted code:

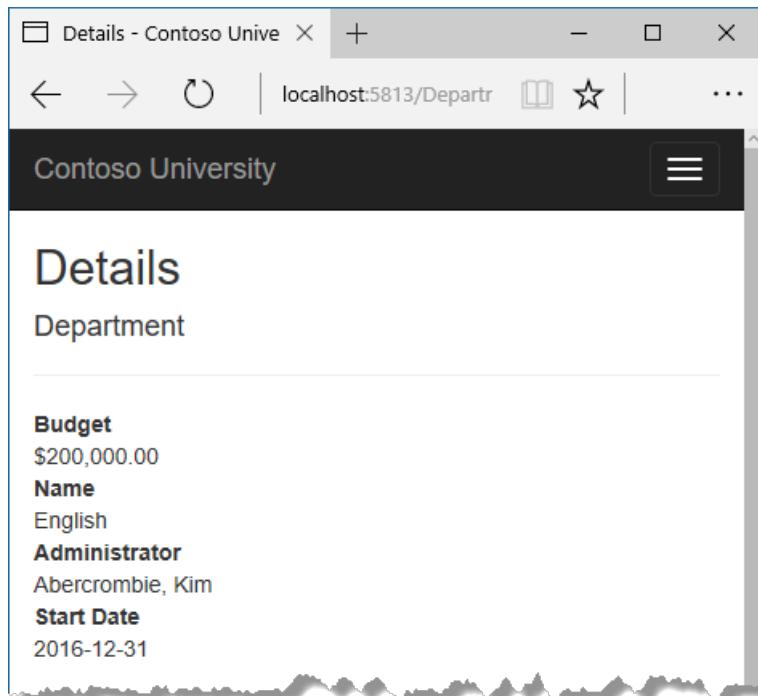

```
public async Task<IActionResult> Details(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    string query = "SELECT * FROM Department WHERE DepartmentID = {0}";
    var department = await _context.Departments
        .FromSql(query, id)
        .Include(d => d.Administrator)
        .AsNoTracking()
        .SingleOrDefaultAsync();

    if (department == null)
    {
        return NotFound();
    }

    return View(department);
}
```

To verify that the new code works correctly, select the **Departments** tab and then **Details** for one of the departments.

## Call a query that returns other types

Earlier you created a student statistics grid for the About page that showed the number of students for each

enrollment date. You got the data from the Students entity set (`_context.Students`) and used LINQ to project the results into a list of `EnrollmentDateGroup` view model objects. Suppose you want to write the SQL itself rather than using LINQ. To do that you need to run a SQL query that returns something other than entity objects. In EF Core 1.0, one way to do that is write ADO.NET code and get the database connection from EF.

In `HomeController.cs`, replace the `About` method with the following code:

```
public async Task<ActionResult> About()
{
    List<EnrollmentDateGroup> groups = new List<EnrollmentDateGroup>();
    var conn = _context.Database.GetDbConnection();
    try
    {
        await conn.OpenAsync();
        using (var command = conn.CreateCommand())
        {
            string query = "SELECT EnrollmentDate, COUNT(*) AS StudentCount "
                + "FROM Person "
                + "WHERE Discriminator = 'Student' "
                + "GROUP BY EnrollmentDate";
            command.CommandText = query;
            DbDataReader reader = await command.ExecuteReaderAsync();

            if (reader.HasRows)
            {
                while (await reader.ReadAsync())
                {
                    var row = new EnrollmentDateGroup { EnrollmentDate = reader.GetDateTime(0), StudentCount =
                        reader.GetInt32(1) };
                    groups.Add(row);
                }
            }
            reader.Dispose();
        }
    }
    finally
    {
        conn.Close();
    }
    return View(groups);
}
```

Add a using statement:

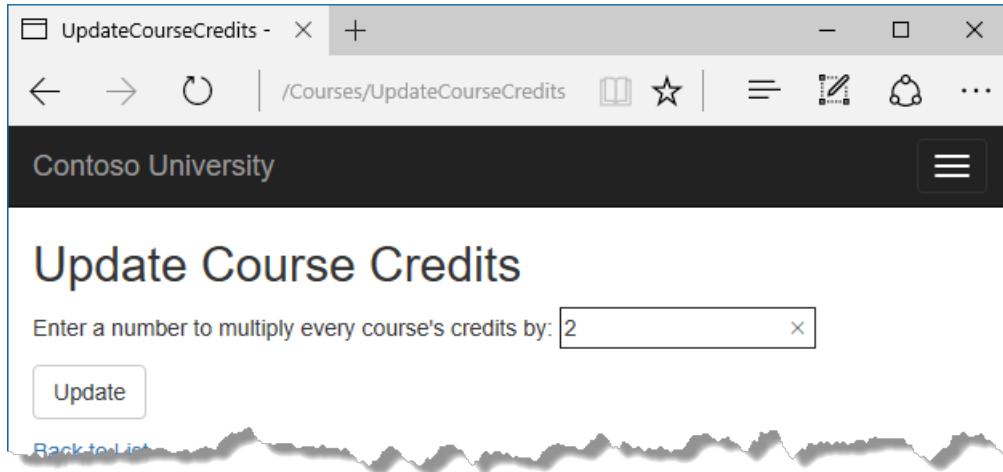

```
using System.Data.Common;
```

Run the app and go to the About page. It displays the same data it did before.

Enrollment Date	Students
9/1/2005	1
9/1/2010	1
9/1/2011	1
9/1/2012	3

## Call an update query

Suppose Contoso University administrators want to perform global changes in the database, such as changing the number of credits for every course. If the university has a large number of courses, it would be inefficient to retrieve them all as entities and change them individually. In this section you'll implement a web page that enables the user to specify a factor by which to change the number of credits for all courses, and you'll make the change by executing a SQL UPDATE statement. The web page will look like the following illustration:

In `CoursesController.cs`, add `UpdateCourseCredits` methods for `HttpGet` and `HttpPost`:

```
public IActionResult UpdateCourseCredits()
{
    return View();
}

[HttpPost]
public async Task<IActionResult> UpdateCourseCredits(int? multiplier)
{
    if (multiplier != null)
    {
        ViewData["RowsAffected"] =
            await _context.Database.ExecuteSqlCommandAsync(
                "UPDATE Course SET Credits = Credits * {0}",
                parameters: multiplier);
    }
    return View();
}
```

When the controller processes an `HttpGet` request, nothing is returned in `ViewData["RowsAffected"]`, and the view displays an empty text box and a submit button, as shown in the preceding illustration.

When the **Update** button is clicked, the `HttpPost` method is called, and `multiplier` has the value entered in the text box. The code then executes the SQL that updates courses and returns the number of affected rows to the view in `ViewData`. When the view gets a `RowsAffected` value, it displays the number of rows updated.

In **Solution Explorer**, right-click the `Views/Courses` folder, and then click **Add > New Item**.

In the **Add New Item** dialog, click **ASP.NET** under **Installed** in the left pane, click **MVC View Page**, and name the new view `UpdateCourseCredits.cshtml`.

In `Views/Courses/UpdateCourseCredits.cshtml`, replace the template code with the following code:

```

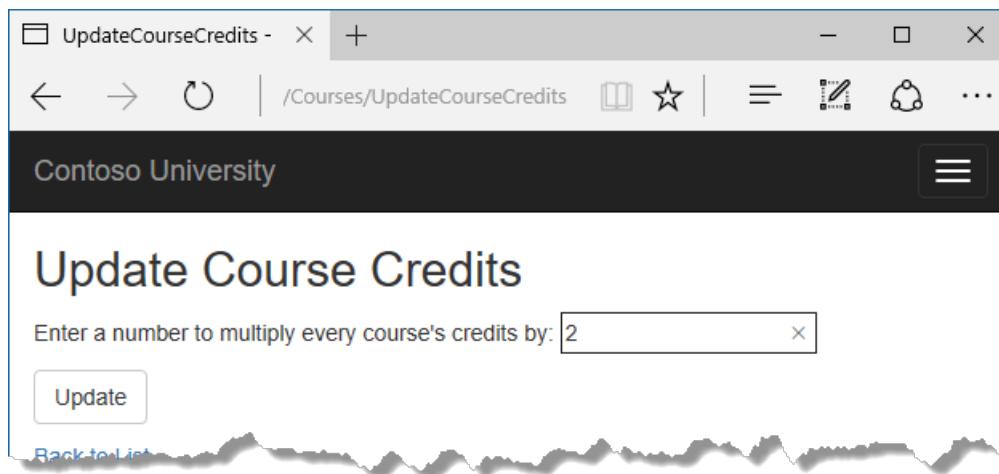

@{
    ViewBag.Title = "UpdateCourseCredits";
}

<h2>Update Course Credits</h2>

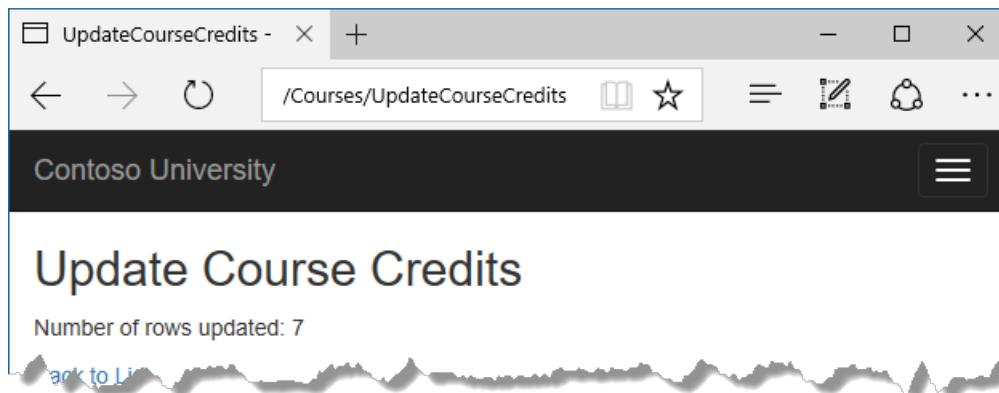

@if (ViewData["RowsAffected"] == null)
{
    <form asp-action="UpdateCourseCredits">
        <div class="form-actions no-color">
            <p>
                Enter a number to multiply every course's credits by: @Html.TextBox("multiplier")
            </p>
            <p>
                <input type="submit" value="Update" class="btn btn-default" />
            </p>
        </div>
    </form>
}
@if (ViewData["RowsAffected"] != null)
{
    <p>
        Number of rows updated: @ViewData["RowsAffected"]
    </p>
}
<div>
    @Html.ActionLink("Back to List", "Index")
</div>

```

Run the `UpdateCourseCredits` method by selecting the **Courses** tab, then adding "/UpdateCourseCredits" to the end of the URL in the browser's address bar (for example: <http://localhost:5813/Courses/UpdateCourseCredits>). Enter a number in the text box:

Click **Update**. You see the number of rows affected:

Click **Back to List** to see the list of courses with the revised number of credits.

Note that production code would ensure that updates always result in valid data. The simplified code shown here could multiply the number of credits enough to result in numbers greater than 5. (The `Credits` property has a `[Range(0, 5)]` attribute.) The update query would work but the invalid data could cause unexpected results in other parts of the system that assume the number of credits is 5 or less.

For more information about raw SQL queries, see [Raw SQL Queries](#).

## Examine SQL sent to the database

Sometimes it's helpful to be able to see the actual SQL queries that are sent to the database. Built-in logging functionality for ASP.NET Core is automatically used by EF Core to write logs that contain the SQL for queries and updates. In this section you'll see some examples of SQL logging.

Open `StudentsController.cs` and in the `Details` method set a breakpoint on the `if (student == null)` statement.

Run the app in debug mode, and go to the Details page for a student.

Go to the **Output** window showing debug output, and you see the query:

```
Microsoft.EntityFrameworkCore.Database.Command:Information: Executed DbCommand (56ms) [Parameters=@__id_0='?'], CommandType='Text', CommandTimeout='30'
SELECT TOP(2) [s].[ID], [s].[Discriminator], [s].[FirstName], [s].[LastName], [s].[EnrollmentDate]
FROM [Person] AS [s]
WHERE ([s].[Discriminator] = N'Student') AND ([s].[ID] = @__id_0)
ORDER BY [s].[ID]
Microsoft.EntityFrameworkCore.Database.Command:Information: Executed DbCommand (122ms) [Parameters=@__id_0='?'], CommandType='Text', CommandTimeout='30'
SELECT [s.Enrollments].[EnrollmentID], [s.Enrollments].[CourseID], [s.Enrollments].[Grade], [s.Enrollments].[StudentID], [e.Course].[CourseID], [e.Course].[Credits], [e.Course].[DepartmentID], [e.Course].[Title]
FROM [Enrollment] AS [s.Enrollments]
INNER JOIN [Course] AS [e.Course] ON [s.Enrollments].[CourseID] = [e.Course].[CourseID]
INNER JOIN (
    SELECT TOP(1) [s0].[ID]
    FROM [Person] AS [s0]
    WHERE ([s0].[Discriminator] = N'Student') AND ([s0].[ID] = @__id_0)
    ORDER BY [s0].[ID]
) AS [t] ON [s.Enrollments].[StudentID] = [t].[ID]
ORDER BY [t].[ID]
```

You'll notice something here that might surprise you: the SQL selects up to 2 rows (`TOP(2)`) from the Person table. The `SingleOrDefaultAsync` method doesn't resolve to 1 row on the server. Here's why:

- If the query would return multiple rows, the method returns null.
- To determine whether the query would return multiple rows, EF has to check if it returns at least 2.

Note that you don't have to use debug mode and stop at a breakpoint to get logging output in the **Output** window. It's just a convenient way to stop the logging at the point you want to look at the output. If you don't do that, logging continues and you have to scroll back to find the parts you're interested in.

## Repository and unit of work patterns

Many developers write code to implement the repository and unit of work patterns as a wrapper around code that works with the Entity Framework. These patterns are intended to create an abstraction layer between the data access layer and the business logic layer of an application. Implementing these patterns can help insulate your application from changes in the data store and can facilitate automated unit testing or test-driven development (TDD). However, writing additional code to implement these patterns isn't always the best choice for applications that use EF, for several reasons:

- The EF context class itself insulates your code from data-store-specific code.
- The EF context class can act as a unit-of-work class for database updates that you do using EF.
- EF includes features for implementing TDD without writing repository code.

For information about how to implement the repository and unit of work patterns, see [the Entity Framework 5 version of this tutorial series](#).

Entity Framework Core implements an in-memory database provider that can be used for testing. For more information, see [Test with InMemory](#).

## Automatic change detection

The Entity Framework determines how an entity has changed (and therefore which updates need to be sent to the database) by comparing the current values of an entity with the original values. The original values are stored when the entity is queried or attached. Some of the methods that cause automatic change detection are the following:

- `DbContext.SaveChanges`
- `DbContext.Entry`
- `ChangeTracker.Entries`

If you're tracking a large number of entities and you call one of these methods many times in a loop, you might get significant performance improvements by temporarily turning off automatic change detection using the `ChangeTracker.AutoDetectChangesEnabled` property. For example:

```
_context.ChangeTracker.AutoDetectChangesEnabled = false;
```

## Entity Framework Core source code and development plans

The Entity Framework Core source is at <https://github.com/aspnet/EntityFrameworkCore>. The EF Core repository contains nightly builds, issue tracking, feature specs, design meeting notes, and [the roadmap for future development](#). You can file or find bugs, and contribute.

Although the source code is open, Entity Framework Core is fully supported as a Microsoft product. The Microsoft Entity Framework team keeps control over which contributions are accepted and tests all code changes to ensure the quality of each release.

## Reverse engineer from existing database

To reverse engineer a data model including entity classes from an existing database, use the `scaffold-dbcontext` command. See the [getting-started tutorial](#).

## Use dynamic LINQ to simplify sort selection code

The [third tutorial in this series](#) shows how to write LINQ code by hard-coding column names in a `switch` statement. With two columns to choose from, this works fine, but if you have many columns the code could get verbose. To solve that problem, you can use the `EF.Property` method to specify the name of the property as a string. To try out this approach, replace the `Index` method in the `StudentsController` with the following code.

```

public async Task<IActionResult> Index(
    string sortOrder,
    string currentFilter,
    string searchString,
    int? page)
{
    ViewData["CurrentSort"] = sortOrder;
    ViewData["NameSortParm"] =
        String.IsNullOrEmpty(sortOrder) ? "LastName_desc" : "";
    ViewData["DateSortParm"] =
        sortOrder == "EnrollmentDate" ? "EnrollmentDate_desc" : "EnrollmentDate";

    if (searchString != null)
    {
        page = 1;
    }
    else
    {
        searchString = currentFilter;
    }

    ViewData["CurrentFilter"] = searchString;

    var students = from s in _context.Students
                  select s;

    if (!String.IsNullOrEmpty(searchString))
    {
        students = students.Where(s => s.LastName.Contains(searchString)
                           || s.FirstMidName.Contains(searchString));
    }

    if (string.IsNullOrEmpty(sortOrder))
    {
        sortOrder = "LastName";
    }

    bool descending = false;
    if (sortOrder.EndsWith("_desc"))
    {
        sortOrder = sortOrder.Substring(0, sortOrder.Length - 5);
        descending = true;
    }

    if (descending)
    {
        students = students.OrderByDescending(e => EF.Property<object>(e, sortOrder));
    }
    else
    {
        students = students.OrderBy(e => EF.Property<object>(e, sortOrder));
    }

    int pageSize = 3;
    return View(await PaginatedList<Student>.CreateAsync(students.AsNoTracking(),
        page ?? 1, pageSize));
}

```

## Next steps

This completes this series of tutorials on using the Entity Framework Core in an ASP.NET MVC application.

For more information about EF Core, see the [Entity Framework Core documentation](#). A book is also available: [Entity Framework Core in Action](#).

For information on how to deploy a web app, see [Host and deploy](#).

For information about other topics related to ASP.NET Core MVC, such as authentication and authorization, see the [ASP.NET Core documentation](#).

## Acknowledgments

Tom Dykstra and Rick Anderson (twitter @RickAndMSFT) wrote this tutorial. Rowan Miller, Diego Vega, and other members of the Entity Framework team assisted with code reviews and helped debug issues that arose while we were writing code for the tutorials.

## Common errors

### ContosoUniversity.dll used by another process

Error message:

```
Cannot open '...bin\Debug\netcoreapp1.0\ContosoUniversity.dll' for writing -- 'The process cannot access the file '...bin\Debug\netcoreapp1.0\ContosoUniversity.dll' because it is being used by another process.'
```

Solution:

Stop the site in IIS Express. Go to the Windows System Tray, find IIS Express and right-click its icon, select the Contoso University site, and then click **Stop Site**.

### Migration scaffolded with no code in Up and Down methods

Possible cause:

The EF CLI commands don't automatically close and save code files. If you have unsaved changes when you run the `migrations add` command, EF won't find your changes.

Solution:

Run the `migrations remove` command, save your code changes and rerun the `migrations add` command.

### Errors while running database update

It's possible to get other errors when making schema changes in a database that has existing data. If you get migration errors you can't resolve, you can either change the database name in the connection string or delete the database. With a new database, there's no data to migrate, and the update-database command is much more likely to complete without errors.

The simplest approach is to rename the database in `appsettings.json`. The next time you run `database update`, a new database will be created.

To delete a database in SSOX, right-click the database, click **Delete**, and then in the **Delete Database** dialog box select **Close existing connections** and click **OK**.

To delete a database by using the CLI, run the `database drop` CLI command:

```
dotnet ef database drop
```

### Error locating SQL Server instance

Error Message:

```
A network-related or instance-specific error occurred while establishing a connection to SQL Server. The server was not found or was not accessible. Verify that the instance name is correct and that SQL Server is
```

configured to allow remote connections. (provider: SQL Network Interfaces, error: 26 - Error Locating Server/Instance Specified)

Solution:

Check the connection string. If you have manually deleted the database file, change the name of the database in the construction string to start over with a new database.

# ASP.NET Core tutorials

6/21/2018 • 2 minutes to read • [Edit Online](#)

The following step-by-step guides for developing ASP.NET Core applications are available:

## Build web apps

Razor Pages is the recommended approach to create a new Web UI app with ASP.NET Core 2.0 and later.

- [Introduction to Razor Pages in ASP.NET Core](#)
- Create a Razor Pages web app with ASP.NET Core
  - [Razor Pages on macOS](#)
  - [Razor Pages with VS Code](#)
- Create an ASP.NET Core MVC web app
  - [Web app with Visual Studio for Mac](#)
  - [Web app with Visual Studio Code on macOS or Linux](#)

## Build Web APIs

- Create a Web API with ASP.NET Core
  - [Web API with Visual Studio for Mac](#)
  - [Web API with Visual Studio Code](#)

# Create a Razor Pages web app with ASP.NET Core on macOS with Visual Studio for Mac

6/21/2018 • 2 minutes to read • [Edit Online](#)

This is a work in progress.

This series explains the basics of building a Razor Pages web app with ASP.NET Core on macOS.

1. [Get started with Razor Pages on macOS](#)
2. [Add a model to a Razor Pages app](#)
3. [Scaffolded Razor Pages](#)
4. [Work with SQLite](#)
5. [Update the pages](#)
6. [Add search](#)

Until the next section is complete, follow the Visual Studio for Windows version.

1. [Add a new field](#)
2. [Add validation](#)

# Get started with Razor Pages in ASP.NET Core on macOS with Visual Studio for Mac

6/21/2018 • 2 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

This tutorial teaches the basics of building an ASP.NET Core Razor Pages web app. We recommend you review [Introduction to Razor Pages](#) before starting this tutorial. Razor Pages is the recommended way to build UI for web applications in ASP.NET Core.

## Prerequisites

[Visual Studio for Mac](#)

## Create a Razor web app

From a terminal, run the following commands:

```
dotnet new webapp -o RazorPagesMovie  
cd RazorPagesMovie  
dotnet run
```

### NOTE

In ASP.NET Core 2.1 or later, `webapp` is an alias of the `razor` argument. If the `dotnet new webapp <OPTIONS>` command loads the `dotnet new` command help instead of creating a new Razor Pages app, install the [.NET Core 2.1 SDK](#).

```
dotnet new razor -o RazorPagesMovie  
cd RazorPagesMovie  
dotnet run
```

The preceding commands use the [.NET Core CLI](#) to create and run a Razor Pages project. Open a browser to <http://localhost:5000> to view the application.

The screenshot shows a web browser window with the title "Home page - RazorPagesMovie". The address bar displays "localhost:5000". The page content includes a navigation bar with links for "RazorPagesMovie", "Home", "About", and "Contact". Below the navigation bar is a large blue banner with the text "ASP.NET Core" and "Windows", "Linux", "OSX". A central message reads "Learn how to build ASP.NET apps that can run anywhere." with a "Learn More" button. At the bottom of the banner is a navigation bar with three dots.

## Application uses

- Sample pages using ASP.NET Core Razor Pages
- Bower for managing client-side libraries
- Theming using Bootstrap

## How to

- Working with Razor Pages

The default template creates **RazorPagesMovie**, **Home**, **About** and **Contact** links and pages. Depending on the size of your browser window, you might need to click the navigation icon to show the links.

The screenshot shows a web browser window with the title "Home page - RazorPagesMovie". The address bar displays "localhost:5000". The page content includes a navigation bar with links for "RazorPagesMovie", "Home", "About", and "Contact". A yellow box highlights the three-line navigation icon in the top right corner of the header. Below the navigation bar is a large blue banner with the text "ASP.NET Core" and "Windows", "Linux", "OSX". A central message reads "Learn how to build ASP.NET apps that can run anywhere." with a "Learn More" button. At the bottom of the banner is a navigation bar with three dots.

## Application uses

- Sample pages using ASP.NET Core Razor Pages
- Bower for managing client-side libraries
- Theming using Bootstrap

## How to

- Working with Razor Pages.
- Manage User Secrets using Secret Manager.
- Use logging to log a message.
- Add packages using NuGet.

Test the links. The **RazorPagesMovie** and **Home** links go to the Index page. The **About** and **Contact** links go to

the [About](#) and [Contact](#) pages, respectively.

## Project files and folders

The following table lists the files and folders in the project. For this tutorial, the *Startup.cs* file is the most important to understand. You don't need to review each link provided below. The links are provided as a reference when you need more information on a file or folder in the project.

FILE OR FOLDER	PURPOSE
wwwroot	Contains static files. See <a href="#">Static files</a> .
Pages	Folder for <a href="#">Razor Pages</a> .
<i>appsettings.json</i>	<a href="#">Configuration</a>
<i>Program.cs</i>	<a href="#">Hosts</a> the ASP.NET Core app.
<i>Startup.cs</i>	Configures services and the request pipeline. See <a href="#">Startup</a> .

### The Pages folder

The *\_Layout.cshtml* file contains common HTML elements (scripts and stylesheets) and sets the layout for the application. For example, when you click on **RazorPagesMovie**, **Home**, **About** or **Contact**, you see the same elements. The common elements include the navigation menu on the top and the header on the bottom of the window. See [Layout](#) for more information.

The *\_ViewStart.cshtml* sets the Razor Pages [Layout](#) property to use the *\_Layout.cshtml* file. See [Layout](#) for more information.

The *\_ViewImports.cshtml* file contains Razor directives that are imported into each Razor Page. See [Importing Shared Directives](#) for more information.

The *\_ValidationScriptsPartial.cshtml* file provides a reference to [jQuery](#) validation scripts. When we add [Create](#) and [Edit](#) pages later in the tutorial, the *\_ValidationScriptsPartial.cshtml* file will be used.

The [About](#), [Contact](#) and [Index](#) pages are basic pages you can use to start an app. The [Error](#) page is used to display error information.

## Open the project

Press **Ctrl+C** to shut down the application.

From Visual Studio, select **File > Open**, and then select the *RazorPagesMovie.csproj* file.

### Launch the app

In Visual Studio, select **Run > Start Without Debugging** to launch the app. Visual Studio starts [Kestrel](#), launches a browser, and navigates to <http://localhost:5000>.

In the next tutorial, we add a model to the project.

NEXT: ADDING A  
MODEL

# Add a model to an ASP.NET Core Razor Pages app with Visual Studio for Mac

6/21/2018 • 4 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section, you add classes for managing movies in a database. You use these classes with [Entity Framework Core](#) (EF Core) to work with a database. EF Core is an object-relational mapping (ORM) framework that simplifies the data access code that you have to write.

The model classes you create are known as POCO classes (from "plain-old CLR objects") because they don't have any dependency on EF Core. They define the properties of the data that are stored in the database.

In this tutorial, you write the model classes first, and EF Core creates the database. An alternate approach not covered here is to [generate model classes from an existing database](#).

[View or download](#) sample.

## Add a data model

- In Solution Explorer, right-click the **RazorPagesMovie** project, and then select **Add > New Folder**. Name the folder *Models*.
- Right-click the *Models* folder, and then select **Add > New File**.
- In the **New File** dialog:
  - Select **General** in the left pane.
  - Select **Empty Class** in the center pain.
  - Name the class **Movie** and select **New**.

Add the following properties to the `Movie` class:

```
using System;

namespace RazorPagesMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

The `ID` field is required by the database for the primary key.

### Add a database context class

Add the following `MovieContext.cs` class to the *Models* folder:

```

using Microsoft.EntityFrameworkCore;

namespace RazorPagesMovie.Models
{
    public class MovieContext : DbContext
    {
        public MovieContext(DbContextOptions<MovieContext> options)
            : base(options)
        {

        }

        public DbSet<Movie> Movie { get; set; }
    }
}

```

The preceding code creates a `DbSet` property for the entity set. In Entity Framework terminology, an entity set typically corresponds to a database table, and an entity corresponds to a row in the table.

## Add a database connection string

Add a connection string to the `appsettings.json` file.

```

{
    "Logging": {
        "IncludeScopes": false,
        "LogLevel": {
            "Default": "Warning"
        }
    },
    "ConnectionStrings": {
        "MovieContext": "Data Source=MvcMovie.db"
    }
}

```

## Register the database context

Register the database context with the [dependency injection](#) container in the `Startup.cs` file.

```

public void ConfigureServices(IServiceCollection services)
{
    services.AddDbContext<MovieContext>(options =>
        options.UseSqlite(Configuration.GetConnectionString("MovieContext")));
    services.AddMvc();
}

```

Right click on a red squiggly line, for example `MovieContext` in the line

`services.AddDbContext<MovieContext>(options => ).` Select **Quick Fix > using RazorPagesMovie.Models;**. Visual studio adds the using statement.

Build the project to verify you don't have any errors.

```

public IConfiguration Configuration { get; }

// This method gets called by the runtime. Use this method to add services to the container.
public void ConfigureServices(IServiceCollection services)
{
    // requires using RazorPagesMovie.Models;
    // and using Microsoft.Extensions.DependencyInjection;
    // and using Microsoft.EntityFrameworkCore;

    services.AddDbContext<MovieContext>()
        .options.UseSqlite(Configuration);
    services.AddMvc();
}

// This method gets called by the runtime. Use this method to configure the HTTP request pipeline.
public void Configure(IApplicationBuilder app, IWebHostEnvironment env)
{
    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
    }
    else
    {
        app.UseExceptionHandler("/Error");
        app.UseHsts();
    }
    app.UseStaticFiles();
    app.UseMvc(routes =>
    {
        routes.MapRoute(
            name: "default",
            template: "{controller=Home}/{action=Index}/{id?}");
    });
}

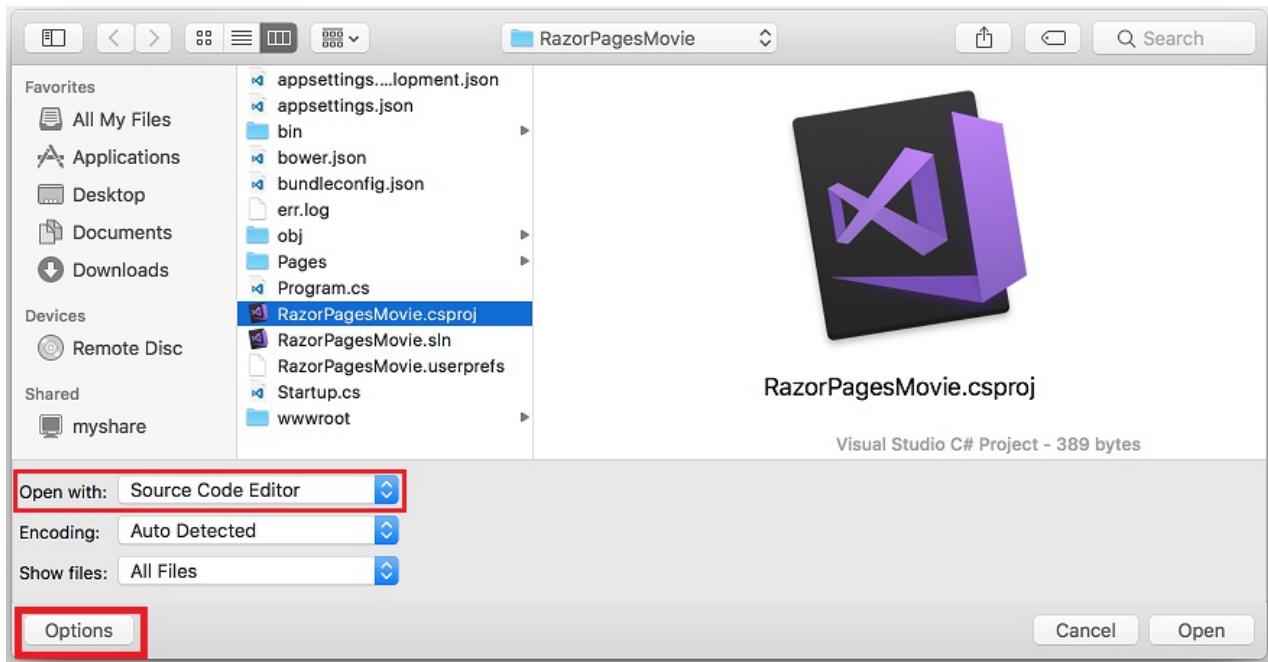

```

## Entity Framework Core NuGet packages for migrations

The EF tools for the command-line interface (CLI) are provided in [Microsoft.EntityFrameworkCore.Tools.DotNet](#). Click on the [Microsoft.EntityFrameworkCore.Tools.DotNet](#) link to get the version number to use. To install this package, add it to the `DotNetCliToolReference` collection in the `.csproj` file. **Note:** You have to install this package by editing the `.csproj` file; you can't use the `install-package` command or the package manager GUI.

To edit a `.csproj` file:

- Select **File > Open**, and then select the `.csproj` file.
- Select **Options**.
- Change **Open with** to **Source Code Editor**.

Add the `Microsoft.EntityFrameworkCore.Tools.DotNet` tool reference to the second `<ItemGroup>`:

```
<Project Sdk="Microsoft.NET.Sdk.Web">
  <PropertyGroup>
    <TargetFramework>netcoreapp2.0</TargetFramework>
  </PropertyGroup>
  <ItemGroup>
    <PackageReference Include="Microsoft.AspNetCore.All" Version="2.0.3" />
  </ItemGroup>
  <ItemGroup>
    <DotNetCliToolReference Include="Microsoft.VisualStudio.Web.CodeGeneration.Tools" Version="2.0.2" />
    <DotNetCliToolReference Include="Microsoft.EntityFrameworkCore.Tools.DotNet" Version="2.0.1" />
  </ItemGroup>
</Project>
```

The version numbers shown in the following code were correct at the time of writing.

## Add scaffold tooling and perform initial migration

From the command line, run the following .NET Core CLI commands:

```
dotnet add package Microsoft.VisualStudio.Web.CodeGeneration.Design
dotnet restore
dotnet ef migrations add InitialCreate
dotnet ef database update
```

The `add package` command installs the tooling required to run the scaffolding engine.

The `ef migrations add InitialCreate` command generates code to create the initial database schema. The schema is based on the model specified in the `DbContext` (In the *Models/MovieContext.cs* file). The `InitialCreate` argument is used to name the migrations. You can use any name, but by convention you choose a name that describes the migration. See [Introduction to migrations](#) for more information.

The `ef database update` command runs the `Up` method in the *Migrations/<time-stamp>\_InitialCreate.cs* file, which creates the database.

### Scaffold the Movie model

- Run the following from the command line (in the project directory that contains the *Program.cs*, *Startup.cs*, and *.csproj* files):

```
dotnet aspnet-codegenerator razorpage -m Movie -dc MovieContext -udl -outDir Pages/Movies --
referenceScriptLibraries
```

If you get the error:

```
No executable found matching command "dotnet-aspnet-codegenerator"
```

Open a command shell to the project directory (The directory that contains the *Program.cs*, *Startup.cs*, and *.csproj* files).

If you get the error:

```
The process cannot access the file
'RazorPagesMovie/bin/Debug/netcoreapp2.0/RazorPagesMovie.dll'
because it is being used by another process.
```

Exit Visual Studio and run the command again.

The following table details the ASP.NET Core code generators' parameters:

PARAMETER	DESCRIPTION
-m	The name of the model.
-dc	The data context.
-udl	Use the default layout.
-outDir	The relative output folder path to create the views.
--referenceScriptLibraries	Adds <code>_ValidationScriptsPartial</code> to Edit and Create pages

Use the `h` switch to get help on the `aspnet-codegenerator razorpage` command:

```
dotnet aspnet-codegenerator razorpage -h
```

## Test the app

- Run the app and append `/Movies` to the URL in the browser (`http://localhost:port/movies`).
- Test the **Create** link.

The screenshot shows a browser window titled "Create - Movie". The address bar indicates a secure connection to `https://localhost:44348/Movies/Create`. The page itself is titled "Create" and has a sub-header "Movie". It contains four input fields: "Title" (value: "The Good, the bad, and the ugly"), "Release Date" (value: "05/30/2018", with a date picker UI), "Genre" (value: "Western"), and "Price" (value: "1.19"). Below these fields is a "Create" button. At the bottom of the page is a link "Back to List" and a copyright notice "© 2018 - RazorPagesMovie".

- Test the **Edit**, **Details**, and **Delete** links.

If you get the error similar to the following, verify you have run migrations and updated the database:

```
An unhandled exception occurred while processing the request.  
'no such table: Movie'.
```

### Add the Pages/Movies files to the project

- In Visual Studio, Right-click the *Pages* folder and select **Add > Add existing Folder**.
- Select the *Movies* folder.
- In the *Choose files to include in the project* dialog, select **Include All**.

The next tutorial explains the files created by scaffolding.

PAGES

# Scaffolded Razor Pages in ASP.NET Core

6/21/2018 • 8 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

This tutorial examines the Razor Pages created by scaffolding in the previous tutorial.

[View or download sample](#).

## The Create, Delete, Details, and Edit pages.

Examine the *Pages/Movies/Index.cshtml.cs* Page Model:

```
using Microsoft.AspNetCore.Mvc.RazorPages;
using Microsoft.EntityFrameworkCore;
using System.Collections.Generic;
using System.Threading.Tasks;
using RazorPagesMovie.Models;

namespace RazorPagesMovie.Pages.Movies
{
    public class IndexModel : PageModel
    {
        private readonly RazorPagesMovie.Models.MovieContext _context;

        public IndexModel(RazorPagesMovie.Models.MovieContext context)
        {
            _context = context;
        }

        public IList<Movie> Movie { get; set; }

        public async Task OnGetAsync()
        {
            Movie = await _context.Movie.ToListAsync();
        }
    }
}
```

```

using Microsoft.AspNetCore.Mvc.RazorPages;
using Microsoft.EntityFrameworkCore;
using RazorPagesMovie.Models;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace RazorPagesMovie.Pages.Movies
{
    public class IndexModel : PageModel
    {
        private readonly RazorPagesMovie.Models.RazorPagesMovieContext _context;

        public IndexModel(RazorPagesMovie.Models.RazorPagesMovieContext context)
        {
            _context = context;
        }

        public IList<Movie> Movie { get; set; }

        public async Task OnGetAsync()
        {
            Movie = await _context.Movie.ToListAsync();
        }
    }
}

```

Razor Pages are derived from `PageModel`. By convention, the `PageModel`-derived class is called `<PageName>Model`. The constructor uses [dependency injection](#) to add the `MovieContext` to the page. All the scaffolded pages follow this pattern. See [Asynchronous code](#) for more information on asynchronous programming with Entity Framework.

When a request is made for the page, the `OnGetAsync` method returns a list of movies to the Razor Page.

`OnGetAsync` or `OnGet` is called on a Razor Page to initialize the state for the page. In this case, `OnGetAsync` gets a list of movies and displays them.

When `OnGet` returns `void` or `OnGetAsync` returns `Task`, no return method is used. When the return type is `IActionResult` or `Task<IActionResult>`, a return statement must be provided. For example, the `Pages/Movies/Create.cshtml.cs` `OnPostAsync` method:

```

public async Task<IActionResult> OnPostAsync()
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    _context.Movie.Add(Movie);
    await _context.SaveChangesAsync();

    return RedirectToPage("./Index");
}

```

Examine the `Pages/Movies/Index.cshtml` Razor Page:

```

@page
@model RazorPagesMovie.Pages.Movies.IndexModel

 @{
    ViewData["Title"] = "Index";
}

<h2>Index</h2>

<p>
    <a asp-page="Create">Create New</a>
</p>
<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].Title)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].ReleaseDate)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].Genre)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].Price)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
@foreach (var item in Model.Movie) {
        <tr>
            <td>
                @Html.DisplayFor(modelItem => item.Title)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.ReleaseDate)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.Genre)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.Price)
            </td>
            <td>
                <a asp-page="./Edit" asp-route-id="@item.ID">Edit</a> |
                <a asp-page="./Details" asp-route-id="@item.ID">Details</a> |
                <a asp-page="./Delete" asp-route-id="@item.ID">Delete</a>
            </td>
        </tr>
}
    </tbody>
</table>

```

Razor can transition from HTML into C# or into Razor-specific markup. When an `@` symbol is followed by a [Razor reserved keyword](#), it transitions into Razor-specific markup, otherwise it transitions into C#.

The `@page` Razor directive makes the file into an MVC action — which means that it can handle requests. `@page` must be the first Razor directive on a page. `@page` is an example of transitioning into Razor-specific markup. See [Razor syntax](#) for more information.

Examine the lambda expression used in the following HTML Helper:

```
@Html.DisplayNameFor(model => model.Movie[0].Title))
```

The `DisplayNameFor` HTML Helper inspects the `Title` property referenced in the lambda expression to determine the display name. The lambda expression is inspected rather than evaluated. That means there is no access violation when `model`, `model.Movie`, or `model.Movie[0]` are `null` or empty. When the lambda expression is evaluated (for example, with `@Html.DisplayFor(modelItem => item.Title)`), the model's property values are evaluated.

## The `@model` directive

```
@page  
@model RazorPagesMovie.Pages.Movies.IndexModel
```

The `@model` directive specifies the type of the model passed to the Razor Page. In the preceding example, the `@model` line makes the `PageModel`-derived class available to the Razor Page. The model is used in the `@Html.DisplayNameFor` and `@Html.DisplayName` [HTML Helpers](#) on the page.

## ViewData and layout

Consider the following code:

```
@page  
@model RazorPagesMovie.Pages.Movies.IndexModel  
  
{@  
    ViewData["Title"] = "Index";  
}
```

The preceding highlighted code is an example of Razor transitioning into C#. The `{` and `}` characters enclose a block of C# code.

The `PageModel` base class has a `ViewData` dictionary property that can be used to add data that you want to pass to a View. You add objects into the `ViewData` dictionary using a key/value pattern. In the preceding sample, the "Title" property is added to the `ViewData` dictionary.

The "Title" property is used in the `Pages/_Layout.cshtml` file. The following markup shows the first few lines of the `Pages/_Layout.cshtml` file.

The "Title" property is used in the `Pages/Shared/_Layout.cshtml` file. The following markup shows the first few lines of the `_Layout.cshtml` file.

```
<!DOCTYPE html>  
<html>  
<head>  
    <meta charset="utf-8" />  
    <meta name="viewport" content="width=device-width, initial-scale=1.0" />  
    <title>@ViewData["Title"] - RazorPagesMovie</title>  
  
    /*Markup removed for brevity.*@
```

The line `/*Markup removed for brevity.*@` is a Razor comment. Unlike HTML comments (`<!-- -->`), Razor comments are not sent to the client.

Run the app and test the links in the project (**Home**, **About**, **Contact**, **Create**, **Edit**, and **Delete**). Each page sets the title, which you can see in the browser tab. When you bookmark a page, the title is used for the bookmark. `Pages/Index.cshtml` and `Pages/Movies/Index.cshtml` currently have the same title, but you can modify them to have

different values.

#### NOTE

You may not be able to enter decimal commas in the `Price` field. To support [jQuery validation](#) for non-US-English locales that use a comma (",") for a decimal point, and non US-English date formats, you must take steps to globalize your app. This [GitHub issue 4076](#) for instructions on adding decimal comma.

The `Layout` property is set in the *Pages/\_ViewStart.cshtml* file:

```
@{  
    Layout = "_Layout";  
}
```

The preceding markup sets the layout file to *Pages/\_Layout.cshtml* for all Razor files under the *Pages* folder. See [Layout](#) for more information.

#### Update the layout

Change the `<title>` element in the *Pages/\_Layout.cshtml* file to use a shorter string.

```
<!DOCTYPE html>  
<html>  
<head>  
    <meta charset="utf-8" />  
    <meta name="viewport" content="width=device-width, initial-scale=1.0" />  
    <title>@ ViewData["Title"] - Movie</title>
```

Find the following anchor element in the *Pages/\_Layout.cshtml* file.

```
<a asp-page="/Index" class="navbar-brand">RazorPagesMovie</a>
```

Replace the preceding element with the following markup.

```
<a asp-page="/Movies/Index" class="navbar-brand">RpMovie</a>
```

The preceding anchor element is a [Tag Helper](#). In this case, it's the [Anchor Tag Helper](#). The `asp-page="/Movies/Index"` Tag Helper attribute and value creates a link to the `/Movies/Index` Razor Page.

Save your changes, and test the app by clicking on the **RpMovie** link. See the *\_Layout.cshtml* file in GitHub.

#### The Create page model

Examine the *Pages/Movies/Create.cshtml.cs* page model:

```
// Unused usings removed.
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using RazorPagesMovie.Models;
using System.Threading.Tasks;

namespace RazorPagesMovie.Pages.Movies
{
    public class CreateModel : PageModel
    {
        private readonly RazorPagesMovie.Models.MovieContext _context;

        public CreateModel(RazorPagesMovie.Models.MovieContext context)
        {
            _context = context;
        }

        public IActionResult OnGet()
        {
            return Page();
        }

        [BindProperty]
        public Movie Movie { get; set; }

        public async Task<IActionResult> OnPostAsync()
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }

            _context.Movie.Add(Movie);
            await _context.SaveChangesAsync();

            return RedirectToPage("./Index");
        }
    }
}
```

```

// Unused usings removed.
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using RazorPagesMovie.Models;
using System.Threading.Tasks;

namespace RazorPagesMovie.Pages.Movies
{
    public class CreateModel : PageModel
    {
        private readonly RazorPagesMovie.Models.RazorPagesMovieContext _context;

        public CreateModel(RazorPagesMovie.Models.RazorPagesMovieContext context)
        {
            _context = context;
        }

        public IActionResult OnGet()
        {
            return Page();
        }

        [BindProperty]
        public Movie Movie { get; set; }

        public async Task<IActionResult> OnPostAsync()
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }

            _context.Movie.Add(Movie);
            await _context.SaveChangesAsync();

            return RedirectToPage("./Index");
        }
    }
}

```

The `OnGet` method initializes any state needed for the page. The Create page doesn't have any state to initialize, so `Page` is returned. Later in the tutorial you see `OnGet` method initialize state. The `Page` method creates a `PageResult` object that renders the *Create.cshtml* page.

The `Movie` property uses the `[BindProperty]` attribute to opt-in to [model binding](#). When the Create form posts the form values, the ASP.NET Core runtime binds the posted values to the `Movie` model.

The `OnPostAsync` method is run when the page posts form data:

```

public async Task<IActionResult> OnPostAsync()
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    _context.Movie.Add(Movie);
    await _context.SaveChangesAsync();

    return RedirectToPage("./Index");
}

```

If there are any model errors, the form is redisplayed, along with any form data posted. Most model errors can be

caught on the client-side before the form is posted. An example of a model error is posting a value for the date field that cannot be converted to a date. We'll talk more about client-side validation and model validation later in the tutorial.

If there are no model errors, the data is saved, and the browser is redirected to the Index page.

## The Create Razor Page

Examine the *Pages/Movies/Create.cshtml* Razor Page file:

```
@page
@model RazorPagesMovie.Pages.Movies.CreateModel

@{
    ViewData["Title"] = "Create";
}

<h2>Create</h2>

<h4>Movie</h4>
<hr />
<div class="row">
    <div class="col-md-4">
        <form method="post">
            <div asp-validation-summary="ModelOnly" class="text-danger"></div>
            <div class="form-group">
                <label asp-for="Movie.Title" class="control-label"></label>
                <input asp-for="Movie.Title" class="form-control" />
                <span asp-validation-for="Movie.Title" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Movie.ReleaseDate" class="control-label"></label>
                <input asp-for="Movie.ReleaseDate" class="form-control" />
                <span asp-validation-for="Movie.ReleaseDate" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Movie.Genre" class="control-label"></label>
                <input asp-for="Movie.Genre" class="form-control" />
                <span asp-validation-for="Movie.Genre" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Movie.Price" class="control-label"></label>
                <input asp-for="Movie.Price" class="form-control" />
                <span asp-validation-for="Movie.Price" class="text-danger"></span>
            </div>
            <div class="form-group">
                <input type="submit" value="Create" class="btn btn-default" />
            </div>
        </form>
    </div>
</div>

<a asp-page="Index">Back to List</a>
</div>

@section Scripts {
    @await Html.RenderPartialAsync("_ValidationScriptsPartial");
}
```

The `<form method="post">` element is a [Form Tag Helper](#). The Form Tag Helper automatically includes an [antiforgery token](#).

The scaffolding engine creates Razor markup for each field in the model (except the ID) similar to the following:

```
<div asp-validation-summary="ModelOnly" class="text-danger"></div>
<div class="form-group">
    <label asp-for="Movie.Title" class="control-label"></label>
    <input asp-for="Movie.Title" class="form-control" />
    <span asp-validation-for="Movie.Title" class="text-danger"></span>
</div>
```

The [Validation Tag Helpers](#) (`<div asp-validation-summary` and `<span asp-validation-for`) display validation errors. Validation is covered in more detail later in this series.

The [Label Tag Helper](#) (`<label asp-for="Movie.Title" class="control-label"></label>`) generates the label caption and `for` attribute for the `Title` property.

The [Input Tag Helper](#) (`<input asp-for="Movie.Title" class="form-control" />`) uses the [DataAnnotations](#) attributes and produces HTML attributes needed for jQuery Validation on the client-side.

The next tutorial explains SQLite and seeding the database.

[PREVIOUS: ADDING A](#)

[MODEL](#)

[NEXT:](#)

[SQLITE](#)

# Work with SQLite in an ASP.NET Core Razor Pages app

6/26/2018 • 2 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

The `MovieContext` object handles the task of connecting to the database and mapping `Movie` objects to database records. The database context is registered with the [Dependency Injection](#) container in the `ConfigureServices` method in the *Startup.cs* file:

```
public void ConfigureServices(IServiceCollection services)
{
    // requires
    // using RazorPagesMovie.Models;
    // using Microsoft.EntityFrameworkCore;

    services.AddDbContext<MovieContext>(options =>
        options.UseSqlite(Configuration.GetConnectionString("MovieContext")));
    services.AddMvc();
}
```

## SQLite

The [SQLite](#) website states:

SQLite is a self-contained, high-reliability, embedded, full-featured, public-domain, SQL database engine.  
SQLite is the most used database engine in the world.

There are many third party tools you can download to manage and view a SQLite database. The image below is from [DB Browser for SQLite](#). If you have a favorite SQLite tool, leave a comment on what you like about it.

The screenshot shows the DB Browser for SQLite interface with the following details:

- Toolbar:** New Database, Open Database, Write Changes, Revert Changes.
- Tab Bar:** Database Structure (selected), Browse Data, Edit Pragmas, Execute SQL.
- Sub-Toolbar:** Create Table, Create Index, Modify Table, Delete Table.
- Table List:**
  - Tables (3):**
    - Movie:** Contains columns ID (INTEGER), Genre (TEXT), Price (TEXT), ReleaseDate (TEXT), and Title (TEXT).
    - \_\_EFMigrationsHistory:** Contains column MigrationId (TEXT).
    - sqlite\_sequence:** Contains columns name (TEXT) and seq (INTEGER).
  - Indices (1):** sqlite\_autoindex\_\_EFMigrationsHis...
  - Views (0):** None.
  - Triggers (0):** None.
- Bottom Right:** UTF-8 encoding indicator.

## Seed the database

Create a new class named `SeedData` in the *Models* folder. Replace the generated code with the following:

```

using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using System;
using System.Linq;

namespace RazorPagesMovie.Models
{
    public static class SeedData
    {
        public static void Initialize(IServiceProvider serviceProvider)
        {
            using (var context = new MovieContext(
                serviceProvider.GetRequiredService<DbContextOptions<MovieContext>>()))
            {
                // Look for any movies.
                if (context.Movie.Any())
                {
                    return; // DB has been seeded
                }

                context.Movie.AddRange(
                    new Movie
                    {
                        Title = "When Harry Met Sally",
                        ReleaseDate = DateTime.Parse("1989-2-12"),
                        Genre = "Romantic Comedy",
                        Price = 7.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters",
                        ReleaseDate = DateTime.Parse("1984-3-13"),
                        Genre = "Comedy",
                        Price = 8.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters 2",
                        ReleaseDate = DateTime.Parse("1986-2-23"),
                        Genre = "Comedy",
                        Price = 9.99M
                    },
                    new Movie
                    {
                        Title = "Rio Bravo",
                        ReleaseDate = DateTime.Parse("1959-4-15"),
                        Genre = "Western",
                        Price = 3.99M
                    }
                );
                context.SaveChanges();
            }
        }
    }
}

```

If there are any movies in the DB, the seed initializer returns.

```
if (context.Movie.Any())
{
    return; // DB has been seeded.
}
```

## Add the seed initializer

Add the seed initializer to the `Main` method in the `Program.cs` file:

```
// Unused usings removed.
using Microsoft.AspNetCore;
using Microsoft.AspNetCore.Hosting;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Logging;
using RazorPagesMovie.Models;
using System;
using Microsoft.EntityFrameworkCore;

namespace RazorPagesMovie
{
    public class Program
    {
        public static void Main(string[] args)
        {
            var host = BuildWebHost(args);

            using (var scope = host.Services.CreateScope())
            {
                var services = scope.ServiceProvider;

                try
                {
                    var context = services.GetRequiredService<MovieContext>();
                    // requires using Microsoft.EntityFrameworkCore;
                    context.Database.Migrate();
                    // Requires using RazorPagesMovie.Models;
                    SeedData.Initialize(services);
                }
                catch (Exception ex)
                {
                    var logger = services.GetRequiredService<ILogger<Program>>();
                    logger.LogError(ex, "An error occurred seeding the DB.");
                }
            }

            host.Run();
        }

        public static IWebHost BuildWebHost(string[] args) =>
            WebHost.CreateDefaultBuilder(args)
                .UseStartup<Startup>()
                .Build();
    }
}
```

## Test the app

Delete all the records in the DB (So the seed method will run). Stop and start the app to seed the database.

The app shows the seeded data.

[PREVIOUS: ADDING A  
MODEL](#)

[NEXT: UPDATE THE  
PAGES](#)

# Update the generated pages

6/21/2018 • 5 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

We have a good start to the movie app, but the presentation isn't ideal. We don't want to see the time (12:00:00 AM in the image below) and **ReleaseDate** should be **Release Date** (two words).

Title	ReleaseDate	Genre	Price
When Harry Met Sally	2/12/1989 12:00:00 AM	Romantic Comedy	7.99
Ghostbusters	3/13/1984 12:00:00 AM	Comedy	8.99
Ghostbusters 2	2/23/1986 12:00:00 AM	Comedy	9.99
Rio Bravo	4/15/1959 12:00:00 AM	Western	3.99

## Update the generated code

Open the *Models/Movie.cs* file and add the highlighted lines shown in the following code:

```
using System;
using System.ComponentModel.DataAnnotations;

namespace RazorPagesMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }

        [Display(Name = "Release Date")]
        [DataType(DataType.Date)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

Right click on a red squiggly line > **Quick Actions and Refactorings** on the [Column] attribute and select

```
using System.ComponentModel.DataAnnotations.Schema;
```

The [Column(TypeName = "decimal(18, 2)")] data annotation is required so Entity Framework Core can correctly map Price to currency in the database. For more information, see [Data Types](#).

The completed model:

```
using System;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

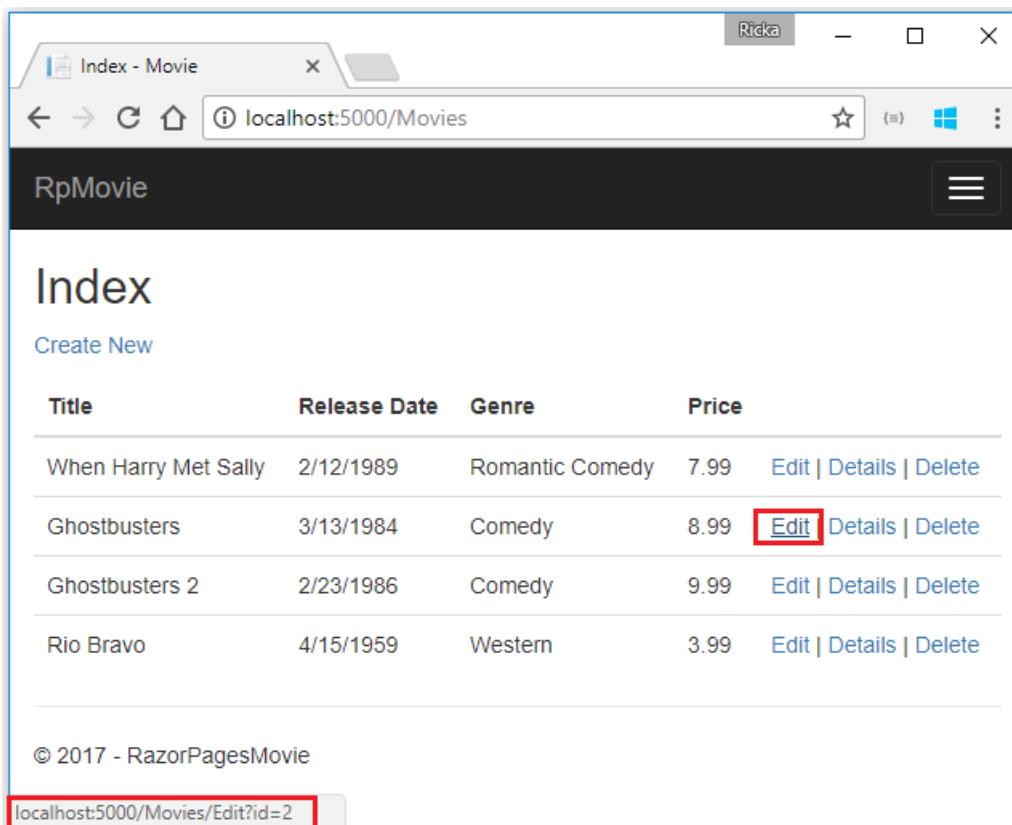

namespace RazorPagesMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }

        [Display(Name = "Release Date")]
        [DataType(DataType.Date)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }

        [Column(TypeName = "decimal(18, 2)")]
        public decimal Price { get; set; }
    }
}
```

We'll cover [DataAnnotations](#) in the next tutorial. The [Display](#) attribute specifies what to display for the name of a field (in this case "Release Date" instead of "ReleaseDate"). The [DataType](#) attribute specifies the type of the data (Date), so the time information stored in the field isn't displayed.

Browse to Pages/Movies and hover over an **Edit** link to see the target URL.

The **Edit**, **Details**, and **Delete** links are generated by the [Anchor Tag Helper](#) in the *Pages/Movies/Index.cshtml* file.

```

@foreach (var item in Model.Movie) {
    <tr>
        <td>
            @Html.DisplayFor(modelItem => item.Title)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.ReleaseDate)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.Genre)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.Price)
        </td>
        <td>
            <a asp-page="./Edit" asp-route-id="@item.ID">Edit</a> | 
            <a asp-page="./Details" asp-route-id="@item.ID">Details</a> | 
            <a asp-page="./Delete" asp-route-id="@item.ID">Delete</a>
        </td>
    </tr>
}
</tbody>
</table>

```

Tag Helpers enable server-side code to participate in creating and rendering HTML elements in Razor files. In the preceding code, the `AnchorTagHelper` dynamically generates the HTML `href` attribute value from the Razor Page (the route is relative), the `asp-page`, and the route id (`asp-route-id`). See [URL generation for Pages](#) for more information.

Use **View Source** from your favorite browser to examine the generated markup. A portion of the generated HTML is shown below:

```

<td>
    <a href="/Movies/Edit?id=1">Edit</a> | 
    <a href="/Movies/Details?id=1">Details</a> | 
    <a href="/Movies/Delete?id=1">Delete</a>
</td>

```

The dynamically-generated links pass the movie ID with a query string (for example,

`http://localhost:5000/Movies/Details?id=2`).

Update the Edit, Details, and Delete Razor Pages to use the "`{id:int}`" route template. Change the page directive for each of these pages from `@page` to `@page "{id:int}"`. Run the app and then view source. The generated HTML adds the ID to the path portion of the URL:

```

<td>
    <a href="/Movies/Edit/1">Edit</a> | 
    <a href="/Movies/Details/1">Details</a> | 
    <a href="/Movies/Delete/1">Delete</a>
</td>

```

A request to the page with the "`{id:int}`" route template that does **not** include the integer will return an HTTP 404 (not found) error. For example, `http://localhost:5000/Movies/Details` will return a 404 error. To make the ID optional, append `?` to the route constraint:

```

@page "{id:int?}"

```

## Update concurrency exception handling

Update the `OnPostAsync` method in the `Pages/Movies/Edit.cshtml.cs` file. The following highlighted code shows the changes:

```
public async Task<IActionResult> OnPostAsync()
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    _context.Attach(Movie).State = EntityState.Modified;

    try
    {
        await _context.SaveChangesAsync();
    }
    catch (DbUpdateConcurrencyException)
    {
        if (!_context.Movie.Any(e => e.ID == Movie.ID))
        {
            return NotFound();
        }
        else
        {
            throw;
        }
    }

    return RedirectToPage("./Index");
}
```

The previous code only detects concurrency exceptions when the first concurrent client deletes the movie, and the second concurrent client posts changes to the movie.

To test the `catch` block:

- Set a breakpoint on `catch (DbUpdateConcurrencyException)`
- Edit a movie.
- In another browser window, select the **Delete** link for the same movie, and then delete the movie.
- In the previous browser window, post changes to the movie.

Production code would generally detect concurrency conflicts when two or more clients concurrently updated a record. See [Handle concurrency conflicts](#) for more information.

### Posting and binding review

Examine the `Pages/Movies/Edit.cshtml.cs` file:

```
public class EditModel : PageModel
{
    private readonly RazorPagesMovie.Models.MovieContext _context;

    public EditModel(RazorPagesMovie.Models.MovieContext context)
    {
        _context = context;
    }

    [BindProperty]
    public Movie Movie { get; set; }

    public async Task<IActionResult> OnGetAsync(int? id)
    {
        if (id == null)
        {
            return NotFound();
        }

        Movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);

        if (Movie == null)
        {
            return NotFound();
        }
        return Page();
    }

    public async Task<IActionResult> OnPostAsync()
    {
        if (!ModelState.IsValid)
        {
            return Page();
        }

        _context.Attach(Movie).State = EntityState.Modified;

        try
        {
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!_context.Movie.Any(e => e.ID == Movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }

        return RedirectToPage("./Index");
    }
}
```

```

public class EditModel : PageModel
{
    private readonly RazorPagesMovie.Models.RazorPagesMovieContext _context;

    public EditModel(RazorPagesMovie.Models.RazorPagesMovieContext context)
    {
        _context = context;
    }

    [BindProperty]
    public Movie Movie { get; set; }

    public async Task<IActionResult> OnGetAsync(int? id)
    {
        if (id == null)
        {
            return NotFound();
        }

        Movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);

        if (Movie == null)
        {
            return NotFound();
        }
        return Page();
    }

    public async Task<IActionResult> OnPostAsync()
    {
        if (!ModelState.IsValid)
        {
            return Page();
        }

        _context.Attach(Movie).State = EntityState.Modified;

        try
        {
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!_context.Movie.Any(e => e.ID == Movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }

        return RedirectToPage("./Index");
    }
}

```

When an HTTP GET request is made to the Movies/Edit page (for example, `http://localhost:5000/Movies/Edit/2`):

- The `OnGetAsync` method fetches the movie from the database and returns the `Page` method.
- The `Page` method renders the `Pages/Movies/Edit.cshtml` Razor Page. The `Pages/Movies/Edit.cshtml` file contains the model directive (`@model RazorPagesMovie.Pages.Movies.EditModel`), which makes the movie model available on the page.
- The Edit form is displayed with the values from the movie.

When the Movies/Edit page is posted:

- The form values on the page are bound to the `Movie` property. The `[BindProperty]` attribute enables [Model binding](#).

```
[BindProperty]  
public Movie Movie { get; set; }
```

- If there are errors in the model state (for example, `ReleaseDate` cannot be converted to a date), the form is posted again with the submitted values.
- If there are no model errors, the movie is saved.

The HTTP GET methods in the Index, Create, and Delete Razor pages follow a similar pattern. The HTTP POST `OnPostAsync` method in the Create Razor Page follows a similar pattern to the `OnPostAsync` method in the Edit Razor Page.

Search is added in the next tutorial.

[PREVIOUS: WORK WITH  
SQLLITE](#)

[ADD  
SEARCH](#)

# Add search to an ASP.NET Core Razor Pages app

6/26/2018 • 3 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this document, search capability is added to the Index page that enables searching movies by *genre* or *name*.

Update the Index page's `OnGetAsync` method with the following code:

```
@{  
    Layout = "_Layout";  
}
```

```
public async Task OnGetAsync(string searchString)  
{  
    var movies = from m in _context.Movie  
                select m;  
  
    if (!String.IsNullOrEmpty(searchString))  
    {  
        movies = movies.Where(s => s.Title.Contains(searchString));  
    }  
  
    Movie = await movies.ToListAsync();  
}
```

The first line of the `OnGetAsync` method creates a [LINQ](#) query to select the movies:

```
var movies = from m in _context.Movie  
            select m;
```

The query is *only* defined at this point, it has **not** been run against the database.

If the `searchString` parameter contains a string, the movies query is modified to filter on the search string:

```
if (!String.IsNullOrEmpty(searchString))  
{  
    movies = movies.Where(s => s.Title.Contains(searchString));  
}
```

The `s => s.Title.Contains()` code is a [Lambda Expression](#). Lambdas are used in method-based [LINQ](#) queries as arguments to standard query operator methods such as the [Where](#) method or `Contains` (used in the preceding code). LINQ queries are not executed when they're defined or when they're modified by calling a method (such as `Where`, `Contains` or `OrderBy`). Rather, query execution is deferred. That means the evaluation of an expression is delayed until its realized value is iterated over or the `ToListAsync` method is called. See [Query Execution](#) for more information.

**Note:** The `Contains` method is run on the database, not in the C# code. The case sensitivity on the query depends on the database and the collation. On SQL Server, `Contains` maps to [SQL LIKE](#), which is case insensitive. In SQLite, with the default collation, it's case sensitive.

Navigate to the Movies page and append a query string such as `?searchString=Ghost` to the URL (for example,

`http://localhost:5000/Movies?searchString=Ghost`). The filtered movies are displayed.

Title	Release Date	Genre	Price	
Ghostbusters	3/13/1984	Comedy	8.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Ghostbusters 2	2/23/1986	Comedy	9.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

If the following route template is added to the Index page, the search string can be passed as a URL segment (for example, `http://localhost:5000/Movies/ghost`).

```
@page "{searchString?}"
```

The preceding route constraint allows searching the title as route data (a URL segment) instead of as a query string value. The `?` in `"{searchString?}"` means this is an optional route parameter.

Title	Release Date	Genre	Price	
Ghostbusters	3/13/1984	Comedy	8.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Ghostbusters 2	2/23/1986	Comedy	9.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

However, you can't expect users to modify the URL to search for a movie. In this step, UI is added to filter movies. If you added the route constraint `"{searchString?}"`, remove it.

Open the `Pages/Movies/Index.cshtml` file, and add the `<form>` markup highlighted in the following code:

```

@page
@model RazorPagesMovie.Pages.Movies.IndexModel

 @{
     ViewData["Title"] = "Index";
 }

<h2>Index</h2>

<p>
    <a href="#" asp-page="Create">Create New</a>
</p>

<form>
    <p>
        Title: <input type="text" name="SearchString">
        <input type="submit" value="Filter" />
    </p>
</form>

<table class="table">
    @*Markup removed for brevity.*@

```

The HTML `<form>` tag uses the [Form Tag Helper](#). When the form is submitted, the filter string is sent to the `Pages/Movies/Index` page. Save the changes and test the filter.

Title	Release Date	Genre	Price	
Ghostbusters	3/13/1984	Comedy	8.99	Edit   Details   Delete
Ghostbusters 2	2/23/1986	Comedy	9.99	Edit   Details   Delete

## Search by genre

Add the following highlighted properties to `Pages/Movies/Index.cshtml.cs`:

```

public class IndexModel : PageModel
{
    private readonly RazorPagesMovie.Models.MovieContext _context;

    public IndexModel(RazorPagesMovie.Models.MovieContext context)
    {
        _context = context;
    }

    public IList<Movie> Movie { get; set; }
    public SelectList Genres { get; set; }
    public string MovieGenre { get; set; }

```

The `SelectList Genres` contains the list of genres. This allows the user to select a genre from the list.

The `MovieGenre` property contains the specific genre the user selects (for example, "Western").

Update the `OnGetAsync` method with the following code:

```

// Requires using Microsoft.AspNetCore.Mvc.Rendering;
public async Task OnGetAsync(string movieGenre, string searchString)
{
    // Use LINQ to get list of genres.
    IQueryable<string> genreQuery = from m in _context.Movie
                                         orderby m.Genre
                                         select m.Genre;

    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    if (!String.IsNullOrEmpty(movieGenre))
    {
        movies = movies.Where(x => x.Genre == movieGenre);
    }
    Genres = new SelectList(await genreQuery.Distinct().ToListAsync());
    Movie = await movies.ToListAsync();
}

```

The following code is a LINQ query that retrieves all the genres from the database.

```

// Use LINQ to get list of genres.
IQueryable<string> genreQuery = from m in _context.Movie
                                         orderby m.Genre
                                         select m.Genre;

```

The `SelectList` of genres is created by projecting the distinct genres.

```
Genres = new SelectList(await genreQuery.Distinct().ToListAsync());
```

## Adding search by genre

Update `Index.cshtml` as follows:

```
@page
@model RazorPagesMovie.Pages.Movies.IndexModel

@{
    ViewData["Title"] = "Index";
}

<h2>Index</h2>

<p>
    <a asp-page="Create">Create New</a>
</p>

<form>
    <p>
        <select asp-for="MovieGenre" asp-items="Model.Genres">
            <option value="">All</option>
        </select>

        Title: <input type="text" name="SearchString">
        <input type="submit" value="Filter" />
    </p>
</form>

<table class="table">
    <thead>
```

Test the app by searching by genre, by movie title, and by both.

FIELD

# Create a Razor Pages web app with ASP.NET Core and Visual Studio Code

6/21/2018 • 2 minutes to read • [Edit Online](#)

This is a work in progress.

This series explains the basics of building a Razor Pages web app with ASP.NET Core using Visual Studio Code.

1. [Get started with Razor Pages with VS Code](#)
2. [Add a model to a Razor Pages app](#)
3. [Scaffolded Razor Pages](#)
4. [Work with SQLite](#)
5. [Update the pages](#)
6. [Add search](#)

Until the next section is complete, follow the Visual Studio for Windows version.

1. [Add a new field](#)
2. [Add validation](#)

# Get started with ASP.NET Core Razor Pages in Visual Studio Code

6/21/2018 • 2 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

This tutorial teaches the basics of building an ASP.NET Core Razor Pages web app. We recommend you complete [Introduction to Razor Pages](#) before starting this tutorial. Razor Pages is the recommended way to build UI for web applications in ASP.NET Core.

## Prerequisites

Install the following:

- [.NET Core SDK 2.0 or later](#)
- [Visual Studio Code](#)
- [C# for Visual Studio Code](#)
- [.NET Core 2.1 SDK or later](#)
- [Visual Studio Code](#)
- [C# for Visual Studio Code](#)

## Create a Razor web app

From a terminal, run the following commands:

```
dotnet new webapp -o RazorPagesMovie  
cd RazorPagesMovie  
dotnet run
```

### NOTE

In ASP.NET Core 2.1 or later, `webapp` is an alias of the `razor` argument. If the `dotnet new webapp <OPTIONS>` command loads the `dotnet new` command help instead of creating a new Razor Pages app, install the [.NET Core 2.1 SDK](#).

```
dotnet new razor -o RazorPagesMovie  
cd RazorPagesMovie  
dotnet run
```

The preceding commands use the [.NET Core CLI](#) to create and run a Razor Pages project. Open a browser to <http://localhost:5000> to view the application.

The screenshot shows a web browser window with the title "Home page - RazorPagesMovie". The address bar displays "localhost:5000". The page content includes a navigation bar with links for "RazorPagesMovie", "Home", "About", and "Contact". Below the navigation bar is a large blue banner with the text "ASP.NET Core" and "Windows", "Linux", "OSX". A central message reads "Learn how to build ASP.NET apps that can run anywhere." with a "Learn More" button. At the bottom of the banner is a navigation bar with three dots.

## Application uses

- Sample pages using ASP.NET Core Razor Pages
- Bower for managing client-side libraries
- Theming using Bootstrap

## How to

- Working with Razor Pages

The default template creates **RazorPagesMovie**, **Home**, **About** and **Contact** links and pages. Depending on the size of your browser window, you might need to click the navigation icon to show the links.

The screenshot shows a web browser window with the title "Home page - RazorPagesMovie". The address bar displays "localhost:5000". The page content includes a navigation bar with links for "RazorPagesMovie", "Home", "About", and "Contact". A yellow box highlights the navigation icon (three horizontal lines) in the top right corner of the header. Below the navigation bar is a large blue banner with the text "ASP.NET Core" and "Windows", "Linux", "OSX". At the bottom of the banner is a navigation bar with three dots.

## Application uses

- Sample pages using ASP.NET Core Razor Pages
- Bower for managing client-side libraries
- Theming using Bootstrap

## How to

- Working with Razor Pages.
- Manage User Secrets using Secret Manager.
- Use logging to log a message.
- Add packages using NuGet.

Test the links. The **RazorPagesMovie** and **Home** links go to the Index page. The **About** and **Contact** links go to

the [About](#) and [Contact](#) pages, respectively.

## Project files and folders

The following table lists the files and folders in the project. For this tutorial, the *Startup.cs* file is the most important to understand. You don't need to review each link provided below. The links are provided as a reference when you need more information on a file or folder in the project.

FILE OR FOLDER	PURPOSE
wwwroot	Contains static files. See <a href="#">Static files</a> .
Pages	Folder for <a href="#">Razor Pages</a> .
<i>appsettings.json</i>	<a href="#">Configuration</a>
<i>Program.cs</i>	<a href="#">Hosts</a> the ASP.NET Core app.
<i>Startup.cs</i>	Configures services and the request pipeline. See <a href="#">Startup</a> .

### The Pages folder

The *\_Layout.cshtml* file contains common HTML elements (scripts and stylesheets) and sets the layout for the application. For example, when you click on **RazorPagesMovie**, **Home**, **About** or **Contact**, you see the same elements. The common elements include the navigation menu on the top and the header on the bottom of the window. See [Layout](#) for more information.

The *\_ViewStart.cshtml* sets the Razor Pages [Layout](#) property to use the *\_Layout.cshtml* file. See [Layout](#) for more information.

The *\_ViewImports.cshtml* file contains Razor directives that are imported into each Razor Page. See [Importing Shared Directives](#) for more information.

The *\_ValidationScriptsPartial.cshtml* file provides a reference to [jQuery](#) validation scripts. When we add [Create](#) and [Edit](#) pages later in the tutorial, the *\_ValidationScriptsPartial.cshtml* file will be used.

The [About](#), [Contact](#) and [Index](#) pages are basic pages you can use to start an app. The [Error](#) page is used to display error information.

## Open the project

Press Ctrl+C to shut down the application.

From Visual Studio Code (VS Code), select **File > Open Folder**, and then select the *RazorPagesMovie* folder.

- Select **Yes** to the **Warn** message "Required assets to build and debug are missing from 'RazorPagesMovie'. Add them?"
- Select **Restore** to the **Info** message "There are unresolved dependencies".

### Launch the app

Press Ctrl+F5 to start the app without debugging. Alternatively, from the **Debug** menu, select **Start Without Debugging**.

In the next tutorial, we add a model to the project.

NEXT: ADDING A

MODEL

# Add a model to an ASP.NET Core Razor Pages app with Visual Studio Code

7/6/2018 • 4 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section, you add classes for managing movies in a database. You use these classes with [Entity Framework Core](#) (EF Core) to work with a database. EF Core is an object-relational mapping (ORM) framework that simplifies the data access code that you have to write.

The model classes you create are known as POCO classes (from "plain-old CLR objects") because they don't have any dependency on EF Core. They define the properties of the data that are stored in the database.

In this tutorial, you write the model classes first, and EF Core creates the database. An alternate approach not covered here is to [generate model classes from an existing database](#).

[View or download](#) sample.

## Add a data model

- Add a folder named *Models*.
- Add a class to the *Models* folder named *Movie.cs*.
- Add the following code to the *Models/Movie.cs* file:

Add the following properties to the `Movie` class:

```
using System;

namespace RazorPagesMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

The `ID` field is required by the database for the primary key.

### Add a database context class

Add the following *MovieContext.cs* class to the *Models* folder:

```

using Microsoft.EntityFrameworkCore;

namespace RazorPagesMovie.Models
{
    public class MovieContext : DbContext
    {
        public MovieContext(DbContextOptions<MovieContext> options)
            : base(options)
        {

        }

        public DbSet<Movie> Movie { get; set; }
    }
}

```

The preceding code creates a `DbSet` property for the entity set. In Entity Framework terminology, an entity set typically corresponds to a database table, and an entity corresponds to a row in the table.

## Add a database connection string

Add a connection string to the `appsettings.json` file.

```

{
  "Logging": {
    "IncludeScopes": false,
    "LogLevel": {
      "Default": "Warning"
    }
  },
  "ConnectionStrings": {
    "MovieContext": "Data Source=MvcMovie.db"
  }
}

```

## Register the database context

Register the database context with the [dependency injection](#) container in the `Startup.cs` file.

```

public void ConfigureServices(IServiceCollection services)
{
    services.AddDbContext<MovieContext>(options =>
        options.UseSqlite(Configuration.GetConnectionString("MovieContext")));
    services.AddMvc();
}

```

Add the following `using` statements at the top of `Startup.cs`:

```

using RazorPagesMovie.Models;
using Microsoft.EntityFrameworkCore;

```

Build the project to verify you don't have any errors.

## Entity Framework Core NuGet packages for migrations

The EF tools for the command-line interface (CLI) are provided in [Microsoft.EntityFrameworkCore.Tools.DotNet](#).

To install this package, add it to the `DotNetCliToolReference` collection in the `.csproj` file. **Note:** You have to install this package by editing the `.csproj` file; you can't use the `install-package` command or the package manager GUI.

Edit the `RazorPagesMovie.csproj` file:

- Select **File > Open File**, and then select the `RazorPagesMovie.csproj` file.

- Add tool reference for `Microsoft.EntityFrameworkCore.Tools.DotNet` to the second `<ItemGroup>`:

```

<Project Sdk="Microsoft.NET.Sdk.Web">
  <PropertyGroup>
    <TargetFramework>netcoreapp2.0</TargetFramework>
  </PropertyGroup>
  <ItemGroup>
    <PackageReference Include="Microsoft.AspNetCore.All" Version="2.0.3" />
  </ItemGroup>
  <ItemGroup>
    <DotNetCliToolReference Include="Microsoft.VisualStudio.Web.CodeGeneration.Tools" Version="2.0.2" />
    <DotNetCliToolReference Include="Microsoft.EntityFrameworkCore.Tools.DotNet" Version="2.0.1" />
  </ItemGroup>
</Project>

```

## Add scaffold tooling and perform initial migration

From the command line, run the following .NET Core CLI commands:

```

dotnet add package Microsoft.VisualStudio.Web.CodeGeneration.Design
dotnet restore
dotnet ef migrations add InitialCreate
dotnet ef database update

```

The `add package` command installs the tooling required to run the scaffolding engine.

The `ef migrations add InitialCreate` command generates code to create the initial database schema. The schema is based on the model specified in the `DbContext` (In the `Models/MovieContext.cs` file). The `InitialCreate` argument is used to name the migrations. You can use any name, but by convention you choose a name that describes the migration. See [Introduction to migrations](#) for more information.

The `ef database update` command runs the `Up` method in the `Migrations/<time-stamp>_InitialCreate.cs` file, which creates the database.

### Scaffold the Movie model

- Open a command window in the project directory (The directory that contains the `Program.cs`, `Startup.cs`, and `.csproj` files).
- Run the following command:

**Note: Run the following command on Windows. For MacOS and Linux, see the next command**

```

dotnet aspnet-codegenerator razorpage -m Movie -dc MovieContext -udl -outDir Pages\Movies --
referenceScriptLibraries

```

- On MacOS and Linux, run the following command:

```

dotnet aspnet-codegenerator razorpage -m Movie -dc MovieContext -udl -outDir Pages/Movies --
referenceScriptLibraries

```

If you get the error:

```

The process cannot access the file
'RazorPagesMovie/bin/Debug/netcoreapp2.0/RazorPagesMovie.dll'
because it is being used by another process.

```

Exit Visual Studio and run the command again.

The following table details the ASP.NET Core code generators' parameters:

PARAMETER	DESCRIPTION
-m	The name of the model.
-dc	The data context.
-udl	Use the default layout.
-outDir	The relative output folder path to create the views.
--referenceScriptLibraries	Adds <code>_ValidationScriptsPartial</code> to Edit and Create pages

Use the `-h` switch to get help on the `aspnet-codegenerator razorpage` command:

```
dotnet aspnet-codegenerator razorpage -h
```

### Test the app

- Run the app and append `/Movies` to the URL in the browser (`http://localhost:port/movies`).
- Test the **Create** link.

The screenshot shows a browser window titled "Create - Movie". The address bar indicates a secure connection to "https://localhost:44348/Movies/Create". The page header "RpMovie" has a three-line menu icon. The main content area is titled "Create" and "Movie". It contains four input fields: "Title" (value: "The Good, the bad, and the ugly"), "Release Date" (value: "05/30/2018", with a "Window Snip" placeholder and a date picker icon), "Genre" (value: "Western"), and "Price" (value: "1.19"). Below these fields is a "Create" button. At the bottom left is a link "Back to List", and at the bottom right is copyright information "© 2018 - RazorPagesMovie".

- Test the **Edit**, **Details**, and **Delete** links.

If you get the error similar to the following, verify you have run migrations and updated the database:

```
An unhandled exception occurred while processing the request.  
'no such table: Movie'.
```

The next tutorial explains the files created by scaffolding.

NEXT: SCAFFOLDED RAZOR

PAGES

# Scaffolded Razor Pages in ASP.NET Core

6/21/2018 • 8 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

This tutorial examines the Razor Pages created by scaffolding in the previous tutorial.

[View or download sample](#).

## The Create, Delete, Details, and Edit pages.

Examine the *Pages/Movies/Index.cshtml.cs* Page Model:

```
using Microsoft.AspNetCore.Mvc.RazorPages;
using Microsoft.EntityFrameworkCore;
using System.Collections.Generic;
using System.Threading.Tasks;
using RazorPagesMovie.Models;

namespace RazorPagesMovie.Pages.Movies
{
    public class IndexModel : PageModel
    {
        private readonly RazorPagesMovie.Models.MovieContext _context;

        public IndexModel(RazorPagesMovie.Models.MovieContext context)
        {
            _context = context;
        }

        public IList<Movie> Movie { get; set; }

        public async Task OnGetAsync()
        {
            Movie = await _context.Movie.ToListAsync();
        }
    }
}
```

```

using Microsoft.AspNetCore.Mvc.RazorPages;
using Microsoft.EntityFrameworkCore;
using RazorPagesMovie.Models;
using System.Collections.Generic;
using System.Threading.Tasks;

namespace RazorPagesMovie.Pages.Movies
{
    public class IndexModel : PageModel
    {
        private readonly RazorPagesMovie.Models.RazorPagesMovieContext _context;

        public IndexModel(RazorPagesMovie.Models.RazorPagesMovieContext context)
        {
            _context = context;
        }

        public IList<Movie> Movie { get; set; }

        public async Task OnGetAsync()
        {
            Movie = await _context.Movie.ToListAsync();
        }
    }
}

```

Razor Pages are derived from `PageModel`. By convention, the `PageModel`-derived class is called `<PageName>Model`. The constructor uses [dependency injection](#) to add the `MovieContext` to the page. All the scaffolded pages follow this pattern. See [Asynchronous code](#) for more information on asynchronous programming with Entity Framework.

When a request is made for the page, the `OnGetAsync` method returns a list of movies to the Razor Page. `OnGetAsync` or `OnGet` is called on a Razor Page to initialize the state for the page. In this case, `OnGetAsync` gets a list of movies and displays them.

When `OnGet` returns `void` or `OnGetAsync` returns `Task`, no return method is used. When the return type is `IActionResult` or `Task<IActionResult>`, a return statement must be provided. For example, the `Pages/Movies/Create.cshtml.cs` `OnPostAsync` method:

```

public async Task<IActionResult> OnPostAsync()
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    _context.Movie.Add(Movie);
    await _context.SaveChangesAsync();

    return RedirectToPage("./Index");
}

```

Examine the `Pages/Movies/Index.cshtml` Razor Page:

```

@page
@model RazorPagesMovie.Pages.Movies.IndexModel

 @{
    ViewData["Title"] = "Index";
}

<h2>Index</h2>

<p>
    <a asp-page="Create">Create New</a>
</p>
<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].Title)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].ReleaseDate)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].Genre)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.Movie[0].Price)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
@foreach (var item in Model.Movie) {
        <tr>
            <td>
                @Html.DisplayFor(modelItem => item.Title)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.ReleaseDate)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.Genre)
            </td>
            <td>
                @Html.DisplayFor(modelItem => item.Price)
            </td>
            <td>
                <a asp-page="./Edit" asp-route-id="@item.ID">Edit</a> |
                <a asp-page="./Details" asp-route-id="@item.ID">Details</a> |
                <a asp-page="./Delete" asp-route-id="@item.ID">Delete</a>
            </td>
        </tr>
}
    </tbody>
</table>

```

Razor can transition from HTML into C# or into Razor-specific markup. When an `@` symbol is followed by a [Razor reserved keyword](#), it transitions into Razor-specific markup, otherwise it transitions into C#.

The `@page` Razor directive makes the file into an MVC action — which means that it can handle requests. `@page` must be the first Razor directive on a page. `@page` is an example of transitioning into Razor-specific markup. See [Razor syntax](#) for more information.

Examine the lambda expression used in the following HTML Helper:

```
@Html.DisplayNameFor(model => model.Movie[0].Title))
```

The `DisplayNameFor` HTML Helper inspects the `Title` property referenced in the lambda expression to determine the display name. The lambda expression is inspected rather than evaluated. That means there is no access violation when `model`, `model.Movie`, or `model.Movie[0]` are `null` or empty. When the lambda expression is evaluated (for example, with `@Html.DisplayFor(modelItem => item.Title)`), the model's property values are evaluated.

### The `@model` directive

```
@page  
@model RazorPagesMovie.Pages.Movies.IndexModel
```

The `@model` directive specifies the type of the model passed to the Razor Page. In the preceding example, the `@model` line makes the `PageModel`-derived class available to the Razor Page. The model is used in the `@Html.DisplayNameFor` and `@Html.DisplayName` [HTML Helpers](#) on the page.

### ViewData and layout

Consider the following code:

```
@page  
@model RazorPagesMovie.Pages.Movies.IndexModel  
  
{@  
    ViewData["Title"] = "Index";  
}
```

The preceding highlighted code is an example of Razor transitioning into C#. The `{` and `}` characters enclose a block of C# code.

The `PageModel` base class has a `ViewData` dictionary property that can be used to add data that you want to pass to a View. You add objects into the `ViewData` dictionary using a key/value pattern. In the preceding sample, the "Title" property is added to the `ViewData` dictionary.

The "Title" property is used in the `Pages/_Layout.cshtml` file. The following markup shows the first few lines of the `Pages/_Layout.cshtml` file.

The "Title" property is used in the `Pages/Shared/_Layout.cshtml` file. The following markup shows the first few lines of the `_Layout.cshtml` file.

```
<!DOCTYPE html>  
<html>  
<head>  
    <meta charset="utf-8" />  
    <meta name="viewport" content="width=device-width, initial-scale=1.0" />  
    <title>@ViewData["Title"] - RazorPagesMovie</title>  
  
    /*Markup removed for brevity.*@
```

The line `/*Markup removed for brevity.*@` is a Razor comment. Unlike HTML comments (`<!-- -->`), Razor comments are not sent to the client.

Run the app and test the links in the project (**Home**, **About**, **Contact**, **Create**, **Edit**, and **Delete**). Each page sets the title, which you can see in the browser tab. When you bookmark a page, the title is used for the bookmark. `Pages/Index.cshtml` and `Pages/Movies/Index.cshtml` currently have the same title, but you can modify them to have

different values.

#### NOTE

You may not be able to enter decimal commas in the `Price` field. To support [jQuery validation](#) for non-US-English locales that use a comma (",") for a decimal point, and non US-English date formats, you must take steps to globalize your app. This [GitHub issue 4076](#) for instructions on adding decimal comma.

The `Layout` property is set in the *Pages/\_ViewStart.cshtml* file:

```
@{  
    Layout = "_Layout";  
}
```

The preceding markup sets the layout file to *Pages/\_Layout.cshtml* for all Razor files under the *Pages* folder. See [Layout](#) for more information.

#### Update the layout

Change the `<title>` element in the *Pages/\_Layout.cshtml* file to use a shorter string.

```
<!DOCTYPE html>  
<html>  
<head>  
    <meta charset="utf-8" />  
    <meta name="viewport" content="width=device-width, initial-scale=1.0" />  
    <title>@ ViewData["Title"] - Movie</title>
```

Find the following anchor element in the *Pages/\_Layout.cshtml* file.

```
<a asp-page="/Index" class="navbar-brand">RazorPagesMovie</a>
```

Replace the preceding element with the following markup.

```
<a asp-page="/Movies/Index" class="navbar-brand">RpMovie</a>
```

The preceding anchor element is a [Tag Helper](#). In this case, it's the [Anchor Tag Helper](#). The `asp-page="/Movies/Index"` Tag Helper attribute and value creates a link to the `/Movies/Index` Razor Page.

Save your changes, and test the app by clicking on the **RpMovie** link. See the *\_Layout.cshtml* file in GitHub.

#### The Create page model

Examine the *Pages/Movies/Create.cshtml.cs* page model:

```
// Unused usings removed.
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using RazorPagesMovie.Models;
using System.Threading.Tasks;

namespace RazorPagesMovie.Pages.Movies
{
    public class CreateModel : PageModel
    {
        private readonly RazorPagesMovie.Models.MovieContext _context;

        public CreateModel(RazorPagesMovie.Models.MovieContext context)
        {
            _context = context;
        }

        public IActionResult OnGet()
        {
            return Page();
        }

        [BindProperty]
        public Movie Movie { get; set; }

        public async Task<IActionResult> OnPostAsync()
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }

            _context.Movie.Add(Movie);
            await _context.SaveChangesAsync();

            return RedirectToPage("./Index");
        }
    }
}
```

```

// Unused usings removed.
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.RazorPages;
using RazorPagesMovie.Models;
using System.Threading.Tasks;

namespace RazorPagesMovie.Pages.Movies
{
    public class CreateModel : PageModel
    {
        private readonly RazorPagesMovie.Models.RazorPagesMovieContext _context;

        public CreateModel(RazorPagesMovie.Models.RazorPagesMovieContext context)
        {
            _context = context;
        }

        public IActionResult OnGet()
        {
            return Page();
        }

        [BindProperty]
        public Movie Movie { get; set; }

        public async Task<IActionResult> OnPostAsync()
        {
            if (!ModelState.IsValid)
            {
                return Page();
            }

            _context.Movie.Add(Movie);
            await _context.SaveChangesAsync();

            return RedirectToPage("./Index");
        }
    }
}

```

The `OnGet` method initializes any state needed for the page. The Create page doesn't have any state to initialize, so `Page` is returned. Later in the tutorial you see `OnGet` method initialize state. The `Page` method creates a `PageResult` object that renders the *Create.cshtml* page.

The `Movie` property uses the `[BindProperty]` attribute to opt-in to [model binding](#). When the Create form posts the form values, the ASP.NET Core runtime binds the posted values to the `Movie` model.

The `OnPostAsync` method is run when the page posts form data:

```

public async Task<IActionResult> OnPostAsync()
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    _context.Movie.Add(Movie);
    await _context.SaveChangesAsync();

    return RedirectToPage("./Index");
}

```

If there are any model errors, the form is redisplayed, along with any form data posted. Most model errors can be

caught on the client-side before the form is posted. An example of a model error is posting a value for the date field that cannot be converted to a date. We'll talk more about client-side validation and model validation later in the tutorial.

If there are no model errors, the data is saved, and the browser is redirected to the Index page.

## The Create Razor Page

Examine the *Pages/Movies/Create.cshtml* Razor Page file:

```
@page
@model RazorPagesMovie.Pages.Movies.CreateModel

@{
    ViewData["Title"] = "Create";
}

<h2>Create</h2>

<h4>Movie</h4>
<hr />
<div class="row">
    <div class="col-md-4">
        <form method="post">
            <div asp-validation-summary="ModelOnly" class="text-danger"></div>
            <div class="form-group">
                <label asp-for="Movie.Title" class="control-label"></label>
                <input asp-for="Movie.Title" class="form-control" />
                <span asp-validation-for="Movie.Title" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Movie.ReleaseDate" class="control-label"></label>
                <input asp-for="Movie.ReleaseDate" class="form-control" />
                <span asp-validation-for="Movie.ReleaseDate" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Movie.Genre" class="control-label"></label>
                <input asp-for="Movie.Genre" class="form-control" />
                <span asp-validation-for="Movie.Genre" class="text-danger"></span>
            </div>
            <div class="form-group">
                <label asp-for="Movie.Price" class="control-label"></label>
                <input asp-for="Movie.Price" class="form-control" />
                <span asp-validation-for="Movie.Price" class="text-danger"></span>
            </div>
            <div class="form-group">
                <input type="submit" value="Create" class="btn btn-default" />
            </div>
        </form>
    </div>
</div>

<a asp-page="Index">Back to List</a>
</div>

@section Scripts {
    @await Html.RenderPartialAsync("_ValidationScriptsPartial");
}
```

The `<form method="post">` element is a [Form Tag Helper](#). The Form Tag Helper automatically includes an [antiforgery token](#).

The scaffolding engine creates Razor markup for each field in the model (except the ID) similar to the following:

```
<div asp-validation-summary="ModelOnly" class="text-danger"></div>
<div class="form-group">
    <label asp-for="Movie.Title" class="control-label"></label>
    <input asp-for="Movie.Title" class="form-control" />
    <span asp-validation-for="Movie.Title" class="text-danger"></span>
</div>
```

The [Validation Tag Helpers](#) (`<div asp-validation-summary` and `<span asp-validation-for`) display validation errors. Validation is covered in more detail later in this series.

The [Label Tag Helper](#) (`<label asp-for="Movie.Title" class="control-label"></label>`) generates the label caption and `for` attribute for the `Title` property.

The [Input Tag Helper](#) (`<input asp-for="Movie.Title" class="form-control" />`) uses the [DataAnnotations](#) attributes and produces HTML attributes needed for jQuery Validation on the client-side.

The next tutorial explains SQLite and seeding the database.

[PREVIOUS: ADDING A](#)

[MODEL](#)

[NEXT:](#)

[SQLITE](#)

# Work with SQLite in an ASP.NET Core Razor Pages app

6/26/2018 • 2 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

The `MovieContext` object handles the task of connecting to the database and mapping `Movie` objects to database records. The database context is registered with the [Dependency Injection](#) container in the `ConfigureServices` method in the *Startup.cs* file:

```
public void ConfigureServices(IServiceCollection services)
{
    // requires
    // using RazorPagesMovie.Models;
    // using Microsoft.EntityFrameworkCore;

    services.AddDbContext<MovieContext>(options =>
        options.UseSqlite(Configuration.GetConnectionString("MovieContext")));
    services.AddMvc();
}
```

## SQLite

The [SQLite](#) website states:

SQLite is a self-contained, high-reliability, embedded, full-featured, public-domain, SQL database engine.  
SQLite is the most used database engine in the world.

There are many third party tools you can download to manage and view a SQLite database. The image below is from [DB Browser for SQLite](#). If you have a favorite SQLite tool, leave a comment on what you like about it.

The screenshot shows the DB Browser for SQLite interface. The title bar reads "DB Browser for SQLite - /Users/ricka/t/MvcMovie/bin/Debug/netcoreapp1.1/MvcMovie.db". The main window has tabs at the top: "Database Structure" (selected), "Browse Data", "Edit Pragmas", and "Execute SQL". Below the tabs are buttons for "Create Table", "Create Index", "Modify Table", and "Delete Table". The main content area displays the database schema:

Name	Type	Schema
Tables (3)		
Movie		CREATE TABLE "Movie" ( "ID" INTEGER NOT NULL CONSTRAINT `ID` PRIMARY KEY AUTOINCREMENT, `Genre` TEXT, `Price` TEXT NOT NULL, `ReleaseDate` TEXT NOT NULL, `Title` TEXT )
ID	INTEGER	'ID` INTEGER NOT NULL PRIMARY KEY AUTOINCREMENT
Genre	TEXT	'Genre` TEXT
Price	TEXT	'Price` TEXT NOT NULL
ReleaseDate	TEXT	'ReleaseDate` TEXT NOT NULL
Title	TEXT	'Title` TEXT
__EFMigrationsHistory		CREATE TABLE "__EFMigrationsHistory" ( "MigrationId" TEXT, "ProductVersion" TEXT )
sqlite_sequence		CREATE TABLE sqlite_sequence(name,seq)
Indices (1)		sqlite_autoindex__EFMigrationsHis...
Views (0)		
Triggers (0)		

## Seed the database

Create a new class named `SeedData` in the *Models* folder. Replace the generated code with the following:

```

using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using System;
using System.Linq;

namespace RazorPagesMovie.Models
{
    public static class SeedData
    {
        public static void Initialize(IServiceProvider serviceProvider)
        {
            using (var context = new MovieContext(
                serviceProvider.GetRequiredService<DbContextOptions<MovieContext>>()))
            {
                // Look for any movies.
                if (context.Movie.Any())
                {
                    return; // DB has been seeded
                }

                context.Movie.AddRange(
                    new Movie
                    {
                        Title = "When Harry Met Sally",
                        ReleaseDate = DateTime.Parse("1989-2-12"),
                        Genre = "Romantic Comedy",
                        Price = 7.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters",
                        ReleaseDate = DateTime.Parse("1984-3-13"),
                        Genre = "Comedy",
                        Price = 8.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters 2",
                        ReleaseDate = DateTime.Parse("1986-2-23"),
                        Genre = "Comedy",
                        Price = 9.99M
                    },
                    new Movie
                    {
                        Title = "Rio Bravo",
                        ReleaseDate = DateTime.Parse("1959-4-15"),
                        Genre = "Western",
                        Price = 3.99M
                    }
                );
                context.SaveChanges();
            }
        }
    }
}

```

If there are any movies in the DB, the seed initializer returns.

```
if (context.Movie.Any())
{
    return; // DB has been seeded.
}
```

## Add the seed initializer

Add the seed initializer to the `Main` method in the `Program.cs` file:

```
// Unused usings removed.
using Microsoft.AspNetCore;
using Microsoft.AspNetCore.Hosting;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Logging;
using RazorPagesMovie.Models;
using System;
using Microsoft.EntityFrameworkCore;

namespace RazorPagesMovie
{
    public class Program
    {
        public static void Main(string[] args)
        {
            var host = BuildWebHost(args);

            using (var scope = host.Services.CreateScope())
            {
                var services = scope.ServiceProvider;

                try
                {
                    var context = services.GetRequiredService<MovieContext>();
                    // requires using Microsoft.EntityFrameworkCore;
                    context.Database.Migrate();
                    // Requires using RazorPagesMovie.Models;
                    SeedData.Initialize(services);
                }
                catch (Exception ex)
                {
                    var logger = services.GetRequiredService<ILogger<Program>>();
                    logger.LogError(ex, "An error occurred seeding the DB.");
                }
            }

            host.Run();
        }

        public static IWebHost BuildWebHost(string[] args) =>
            WebHost.CreateDefaultBuilder(args)
                .UseStartup<Startup>()
                .Build();
    }
}
```

## Test the app

Delete all the records in the DB (So the seed method will run). Stop and start the app to seed the database.

The app shows the seeded data.

[PREVIOUS: ADDING A  
MODEL](#)

[NEXT: UPDATE THE  
PAGES](#)

# Update the generated pages

6/21/2018 • 5 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

We have a good start to the movie app, but the presentation isn't ideal. We don't want to see the time (12:00:00 AM in the image below) and **ReleaseDate** should be **Release Date** (two words).

Title	ReleaseDate	Genre	Price
When Harry Met Sally	2/12/1989 12:00:00 AM	Romantic Comedy	7.99
Ghostbusters	3/13/1984 12:00:00 AM	Comedy	8.99
Ghostbusters 2	2/23/1986 12:00:00 AM	Comedy	9.99
Rio Bravo	4/15/1959 12:00:00 AM	Western	3.99

## Update the generated code

Open the *Models/Movie.cs* file and add the highlighted lines shown in the following code:

```
using System;
using System.ComponentModel.DataAnnotations;

namespace RazorPagesMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }

        [Display(Name = "Release Date")]
        [DataType(DataType.Date)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

Right click on a red squiggly line > **Quick Actions and Refactorings** on the [Column] attribute and select

```
using System.ComponentModel.DataAnnotations.Schema;
```

The [Column(TypeName = "decimal(18, 2)")] data annotation is required so Entity Framework Core can correctly map Price to currency in the database. For more information, see [Data Types](#).

The completed model:

```
using System;
using System.ComponentModel.DataAnnotations;
using System.ComponentModel.DataAnnotations.Schema;

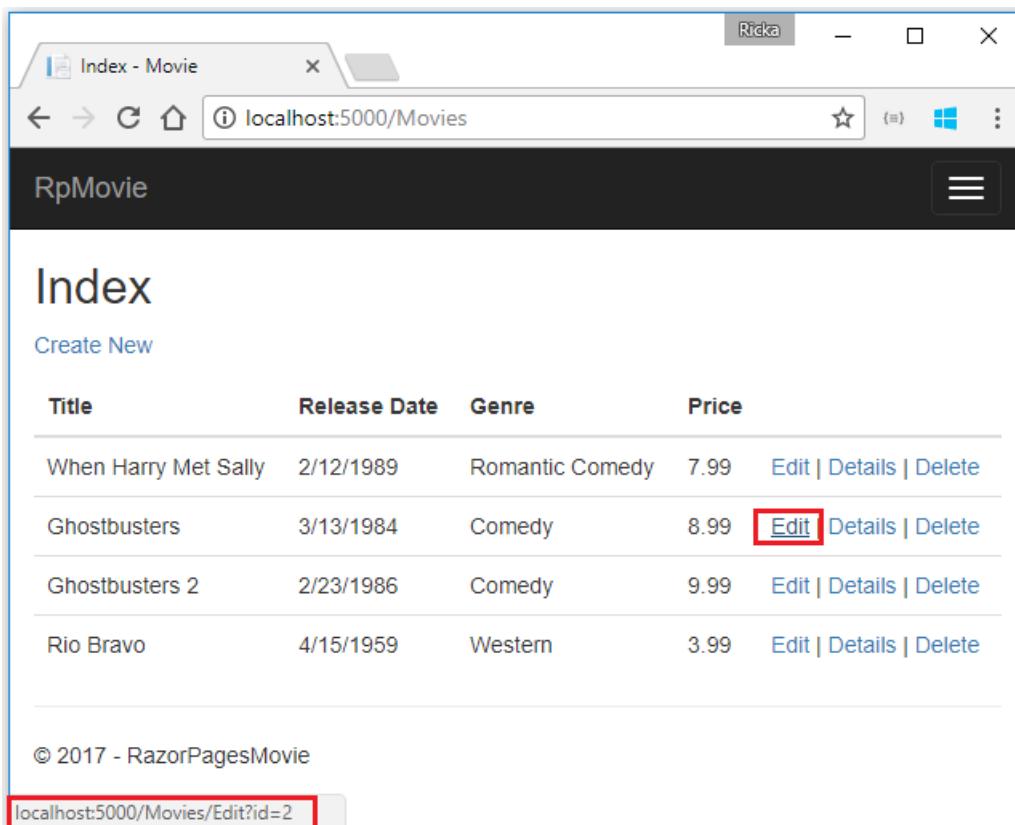

namespace RazorPagesMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }

        [Display(Name = "Release Date")]
        [DataType(DataType.Date)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }

        [Column(TypeName = "decimal(18, 2)")]
        public decimal Price { get; set; }
    }
}
```

We'll cover [DataAnnotations](#) in the next tutorial. The [Display](#) attribute specifies what to display for the name of a field (in this case "Release Date" instead of "ReleaseDate"). The [DataType](#) attribute specifies the type of the data (Date), so the time information stored in the field isn't displayed.

Browse to Pages/Movies and hover over an **Edit** link to see the target URL.

The **Edit**, **Details**, and **Delete** links are generated by the [Anchor Tag Helper](#) in the *Pages/Movies/Index.cshtml* file.

```

@foreach (var item in Model.Movie) {
    <tr>
        <td>
            @Html.DisplayFor(modelItem => item.Title)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.ReleaseDate)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.Genre)
        </td>
        <td>
            @Html.DisplayFor(modelItem => item.Price)
        </td>
        <td>
            <a asp-page="./Edit" asp-route-id="@item.ID">Edit</a> | 
            <a asp-page="./Details" asp-route-id="@item.ID">Details</a> | 
            <a asp-page="./Delete" asp-route-id="@item.ID">Delete</a>
        </td>
    </tr>
}
</tbody>
</table>

```

Tag Helpers enable server-side code to participate in creating and rendering HTML elements in Razor files. In the preceding code, the `AnchorTagHelper` dynamically generates the HTML `href` attribute value from the Razor Page (the route is relative), the `asp-page`, and the route id (`asp-route-id`). See [URL generation for Pages](#) for more information.

Use **View Source** from your favorite browser to examine the generated markup. A portion of the generated HTML is shown below:

```

<td>
    <a href="/Movies/Edit?id=1">Edit</a> | 
    <a href="/Movies/Details?id=1">Details</a> | 
    <a href="/Movies/Delete?id=1">Delete</a>
</td>

```

The dynamically-generated links pass the movie ID with a query string (for example,

`http://localhost:5000/Movies/Details?id=2`).

Update the Edit, Details, and Delete Razor Pages to use the "`{id:int}`" route template. Change the page directive for each of these pages from `@page` to `@page "{id:int}"`. Run the app and then view source. The generated HTML adds the ID to the path portion of the URL:

```

<td>
    <a href="/Movies/Edit/1">Edit</a> | 
    <a href="/Movies/Details/1">Details</a> | 
    <a href="/Movies/Delete/1">Delete</a>
</td>

```

A request to the page with the "`{id:int}`" route template that does **not** include the integer will return an HTTP 404 (not found) error. For example, `http://localhost:5000/Movies/Details` will return a 404 error. To make the ID optional, append `?` to the route constraint:

```

@page "{id:int?}"

```

## Update concurrency exception handling

Update the `OnPostAsync` method in the `Pages/Movies/Edit.cshtml.cs` file. The following highlighted code shows the changes:

```
public async Task<IActionResult> OnPostAsync()
{
    if (!ModelState.IsValid)
    {
        return Page();
    }

    _context.Attach(Movie).State = EntityState.Modified;

    try
    {
        await _context.SaveChangesAsync();
    }
    catch (DbUpdateConcurrencyException)
    {
        if (!_context.Movie.Any(e => e.ID == Movie.ID))
        {
            return NotFound();
        }
        else
        {
            throw;
        }
    }

    return RedirectToPage("./Index");
}
```

The previous code only detects concurrency exceptions when the first concurrent client deletes the movie, and the second concurrent client posts changes to the movie.

To test the `catch` block:

- Set a breakpoint on `catch (DbUpdateConcurrencyException)`
- Edit a movie.
- In another browser window, select the **Delete** link for the same movie, and then delete the movie.
- In the previous browser window, post changes to the movie.

Production code would generally detect concurrency conflicts when two or more clients concurrently updated a record. See [Handle concurrency conflicts](#) for more information.

### Posting and binding review

Examine the `Pages/Movies/Edit.cshtml.cs` file:

```
public class EditModel : PageModel
{
    private readonly RazorPagesMovie.Models.MovieContext _context;

    public EditModel(RazorPagesMovie.Models.MovieContext context)
    {
        _context = context;
    }

    [BindProperty]
    public Movie Movie { get; set; }

    public async Task<IActionResult> OnGetAsync(int? id)
    {
        if (id == null)
        {
            return NotFound();
        }

        Movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);

        if (Movie == null)
        {
            return NotFound();
        }
        return Page();
    }

    public async Task<IActionResult> OnPostAsync()
    {
        if (!ModelState.IsValid)
        {
            return Page();
        }

        _context.Attach(Movie).State = EntityState.Modified;

        try
        {
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!_context.Movie.Any(e => e.ID == Movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }

        return RedirectToPage("./Index");
    }
}
```

```

public class EditModel : PageModel
{
    private readonly RazorPagesMovie.Models.RazorPagesMovieContext _context;

    public EditModel(RazorPagesMovie.Models.RazorPagesMovieContext context)
    {
        _context = context;
    }

    [BindProperty]
    public Movie Movie { get; set; }

    public async Task<IActionResult> OnGetAsync(int? id)
    {
        if (id == null)
        {
            return NotFound();
        }

        Movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);

        if (Movie == null)
        {
            return NotFound();
        }
        return Page();
    }

    public async Task<IActionResult> OnPostAsync()
    {
        if (!ModelState.IsValid)
        {
            return Page();
        }

        _context.Attach(Movie).State = EntityState.Modified;

        try
        {
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!_context.Movie.Any(e => e.ID == Movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
    }

    return RedirectToPage("./Index");
}
}

```

When an HTTP GET request is made to the Movies/Edit page (for example, `http://localhost:5000/Movies/Edit/2`):

- The `OnGetAsync` method fetches the movie from the database and returns the `Page` method.
- The `Page` method renders the `Pages/Movies/Edit.cshtml` Razor Page. The `Pages/Movies/Edit.cshtml` file contains the model directive (`@model RazorPagesMovie.Pages.Movies.EditModel`), which makes the movie model available on the page.
- The Edit form is displayed with the values from the movie.

When the Movies/Edit page is posted:

- The form values on the page are bound to the `Movie` property. The `[BindProperty]` attribute enables [Model binding](#).

```
[BindProperty]  
public Movie Movie { get; set; }
```

- If there are errors in the model state (for example, `ReleaseDate` cannot be converted to a date), the form is posted again with the submitted values.
- If there are no model errors, the movie is saved.

The HTTP GET methods in the Index, Create, and Delete Razor pages follow a similar pattern. The HTTP POST `OnPostAsync` method in the Create Razor Page follows a similar pattern to the `OnPostAsync` method in the Edit Razor Page.

Search is added in the next tutorial.

[PREVIOUS: WORKING WITH  
SQLLITE](#)

[ADD  
SEARCH](#)

# Add search to an ASP.NET Core Razor Pages app

6/26/2018 • 3 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this document, search capability is added to the Index page that enables searching movies by *genre* or *name*.

Update the Index page's `OnGetAsync` method with the following code:

```
@{  
    Layout = "_Layout";  
}
```

```
public async Task OnGetAsync(string searchString)  
{  
    var movies = from m in _context.Movie  
                 select m;  
  
    if (!String.IsNullOrEmpty(searchString))  
    {  
        movies = movies.Where(s => s.Title.Contains(searchString));  
    }  
  
    Movie = await movies.ToListAsync();  
}
```

The first line of the `OnGetAsync` method creates a [LINQ](#) query to select the movies:

```
var movies = from m in _context.Movie  
             select m;
```

The query is *only* defined at this point, it has **not** been run against the database.

If the `searchString` parameter contains a string, the movies query is modified to filter on the search string:

```
if (!String.IsNullOrEmpty(searchString))  
{  
    movies = movies.Where(s => s.Title.Contains(searchString));  
}
```

The `s => s.Title.Contains()` code is a [Lambda Expression](#). Lambdas are used in method-based [LINQ](#) queries as arguments to standard query operator methods such as the [Where](#) method or `Contains` (used in the preceding code). LINQ queries are not executed when they're defined or when they're modified by calling a method (such as `Where`, `Contains` or `OrderBy`). Rather, query execution is deferred. That means the evaluation of an expression is delayed until its realized value is iterated over or the `ToListAsync` method is called. See [Query Execution](#) for more information.

**Note:** The `Contains` method is run on the database, not in the C# code. The case sensitivity on the query depends on the database and the collation. On SQL Server, `Contains` maps to [SQL LIKE](#), which is case insensitive. In SQLite, with the default collation, it's case sensitive.

Navigate to the Movies page and append a query string such as `?searchString=Ghost` to the URL (for example,

`http://localhost:5000/Movies?searchString=Ghost`). The filtered movies are displayed.

The screenshot shows a browser window titled "Index - Movie". The address bar contains the URL "localhost:5000/Movies?searchString=Ghost". The main content area is titled "RpMovie" and "Index". It features a "Create New" link and a table with columns: Title, Release Date, Genre, and Price. Two rows are present: "Ghostbusters" (Release Date: 3/13/1984, Genre: Comedy, Price: 8.99) and "Ghostbusters 2" (Release Date: 2/23/1986, Genre: Comedy, Price: 9.99). Each row has "Edit | Details | Delete" links. At the bottom, there is a copyright notice: "© 2017 - RazorPagesMovie".

Title	Release Date	Genre	Price
Ghostbusters	3/13/1984	Comedy	8.99
Ghostbusters 2	2/23/1986	Comedy	9.99

If the following route template is added to the Index page, the search string can be passed as a URL segment (for example, `http://localhost:5000/Movies/ghost`).

```
@page "{searchString?}"
```

The preceding route constraint allows searching the title as route data (a URL segment) instead of as a query string value. The `?` in `"{searchString?}"` means this is an optional route parameter.

The screenshot shows a browser window titled "Index - Movie". The address bar contains the URL "localhost:5000/Movies/Ghost". The main content area is titled "RpMovie" and "Index". It features a "Create New" link and a table with columns: Title, Release Date, Genre, and Price. Two rows are present: "Ghostbusters" (Release Date: 3/13/1984, Genre: Comedy, Price: 8.99) and "Ghostbusters 2" (Release Date: 2/23/1986, Genre: Comedy, Price: 9.99). Each row has "Edit | Details | Delete" links. At the bottom, there is a copyright notice: "© 2017 - RazorPagesMovie".

Title	Release Date	Genre	Price
Ghostbusters	3/13/1984	Comedy	8.99
Ghostbusters 2	2/23/1986	Comedy	9.99

However, you can't expect users to modify the URL to search for a movie. In this step, UI is added to filter movies. If you added the route constraint `"{searchString?}"`, remove it.

Open the `Pages/Movies/Index.cshtml` file, and add the `<form>` markup highlighted in the following code:

```

@page
@model RazorPagesMovie.Pages.Movies.IndexModel

 @{
     ViewData["Title"] = "Index";
 }

<h2>Index</h2>

<p>
    <a asp-page="Create">Create New</a>
</p>

<form>
    <p>
        Title: <input type="text" name="SearchString">
        <input type="submit" value="Filter" />
    </p>
</form>

<table class="table">
    @*Markup removed for brevity.*@

```

The HTML `<form>` tag uses the [Form Tag Helper](#). When the form is submitted, the filter string is sent to the `Pages/Movies/Index` page. Save the changes and test the filter.

Title	Release Date	Genre	Price	
Ghostbusters	3/13/1984	Comedy	8.99	Edit   Details   Delete
Ghostbusters 2	2/23/1986	Comedy	9.99	Edit   Details   Delete

© 2017 - RazorPagesMovie

## Search by genre

Add the following highlighted properties to `Pages/Movies/Index.cshtml.cs`:

```

public class IndexModel : PageModel
{
    private readonly RazorPagesMovie.Models.MovieContext _context;

    public IndexModel(RazorPagesMovie.Models.MovieContext context)
    {
        _context = context;
    }

    public IList<Movie> Movie { get; set; }
    public SelectList Genres { get; set; }
    public string MovieGenre { get; set; }

```

The `SelectList Genres` contains the list of genres. This allows the user to select a genre from the list.

The `MovieGenre` property contains the specific genre the user selects (for example, "Western").

Update the `OnGetAsync` method with the following code:

```

// Requires using Microsoft.AspNetCore.Mvc.Rendering;
public async Task OnGetAsync(string movieGenre, string searchString)
{
    // Use LINQ to get list of genres.
    IQueryable<string> genreQuery = from m in _context.Movie
                                         orderby m.Genre
                                         select m.Genre;

    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    if (!String.IsNullOrEmpty(movieGenre))
    {
        movies = movies.Where(x => x.Genre == movieGenre);
    }
    Genres = new SelectList(await genreQuery.Distinct().ToListAsync());
    Movie = await movies.ToListAsync();
}

```

The following code is a LINQ query that retrieves all the genres from the database.

```

// Use LINQ to get list of genres.
IQueryable<string> genreQuery = from m in _context.Movie
                                         orderby m.Genre
                                         select m.Genre;

```

The `SelectList` of genres is created by projecting the distinct genres.

```
Genres = new SelectList(await genreQuery.Distinct().ToListAsync());
```

## Adding search by genre

Update `Index.cshtml` as follows:

```
@page
@model RazorPagesMovie.Pages.Movies.IndexModel

@{
    ViewData["Title"] = "Index";
}

<h2>Index</h2>

<p>
    <a asp-page="Create">Create New</a>
</p>

<form>
    <p>
        <select asp-for="MovieGenre" asp-items="Model.Genres">
            <option value="">All</option>
        </select>

        Title: <input type="text" name="SearchString">
        <input type="submit" value="Filter" />
    </p>
</form>

<table class="table">
    <thead>
```

Test the app by searching by genre, by movie title, and by both.

# Create a web app with ASP.NET Core MVC on macOS with Visual Studio for Mac

6/21/2018 • 2 minutes to read • [Edit Online](#)

This series of tutorials teaches you the basics of building an ASP.NET Core MVC web app using Visual Studio for Mac.

This tutorial teaches ASP.NET Core MVC web development with controllers and views. Razor Pages is a feature of the ASP.NET Core MVC framework that makes building and testing web UI easier and more productive. You can use Razor pages alongside controllers and views in the same project.

After using Razor pages, many developers prefer it over controllers and views. We recommend you try the [Razor Pages](#) tutorial before the MVC/Controller/Views version. The Razor Pages tutorial:

- Is the preferred approach for new application development.
- Is easier to follow.
- Covers more features.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub issue](#).

1. [Get started](#)
2. [Add a controller](#)
3. [Add a view](#)
4. [Add a model](#)
5. [SQLite](#)
6. [Controller methods and views](#)
7. [Add search](#)
8. [Add a new field](#)
9. [Add validation](#)
10. [Examine the Details and Delete methods](#)

# Get started with ASP.NET Core MVC and Visual Studio for Mac

6/21/2018 • 2 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

This tutorial teaches you the basics of building an ASP.NET Core MVC web app using [Visual Studio for Mac](#).

This tutorial teaches ASP.NET Core MVC web development with controllers and views. Razor Pages is a feature of the ASP.NET Core MVC framework that makes building and testing web UI easier and more productive. You can use Razor pages alongside controllers and views in the same project.

After using Razor pages, many developers prefer it over controllers and views. We recommend you try the [Razor Pages](#) tutorial before the MVC/Controller/Views version. The Razor Pages tutorial:

- Is the preferred approach for new application development.
- Is easier to follow.
- Covers more features.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub issue](#).

There are 3 versions of this tutorial:

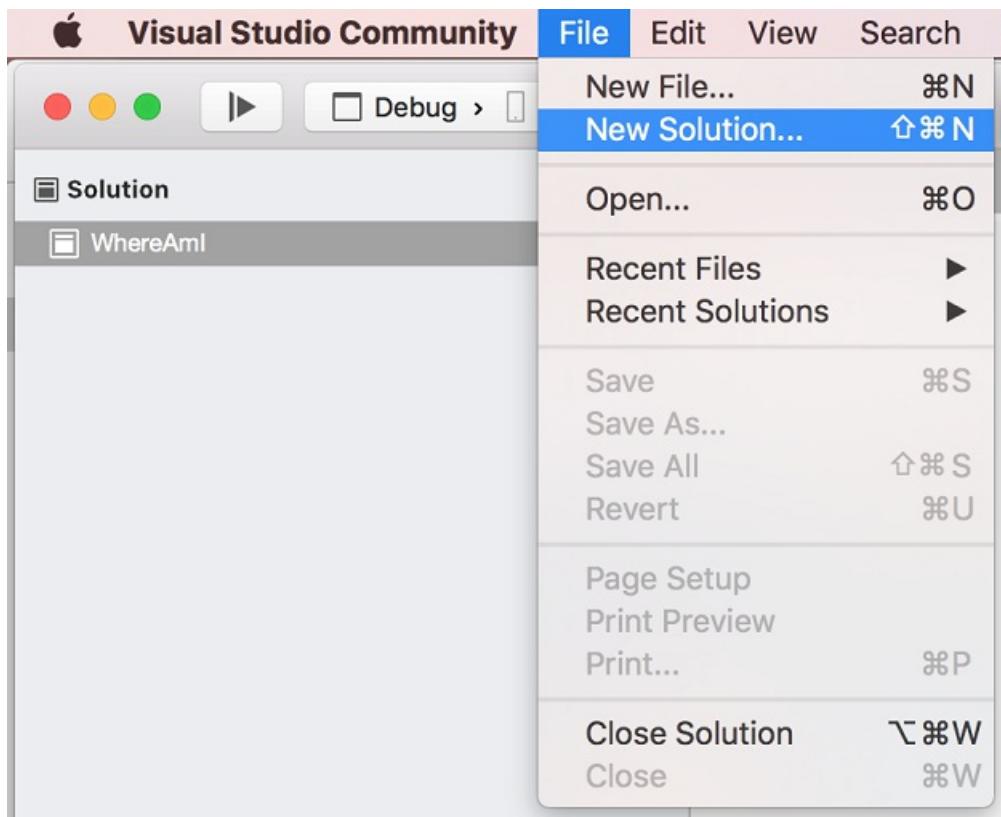

- macOS: [Build an ASP.NET Core MVC app with Visual Studio for Mac](#)
- Windows: [Build an ASP.NET Core MVC app with Visual Studio](#)
- Linux, macOS, and Windows: [Build an ASP.NET Core MVC app with Visual Studio Code](#)

## Prerequisites

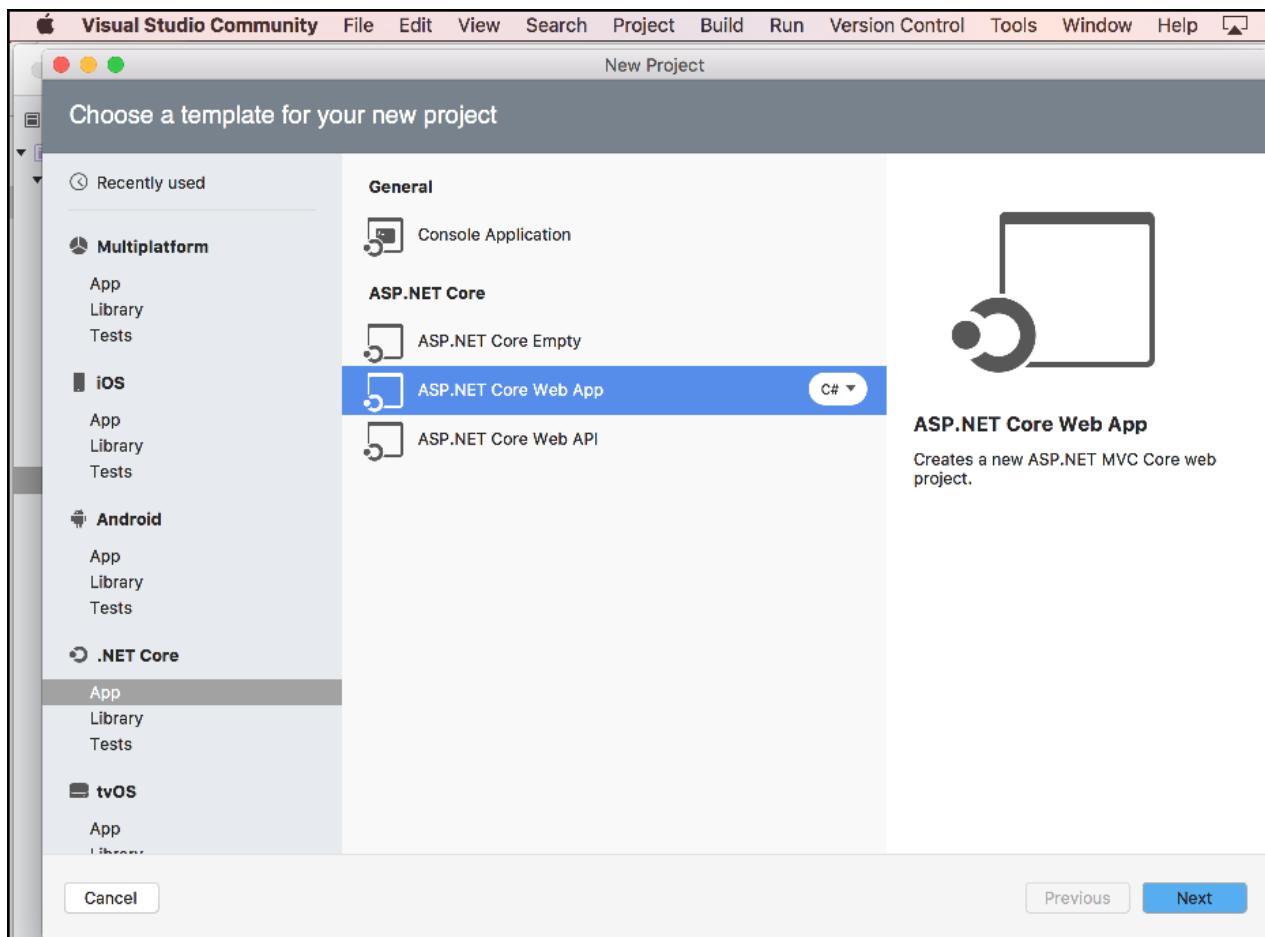

[Visual Studio for Mac](#)

## Create a web app

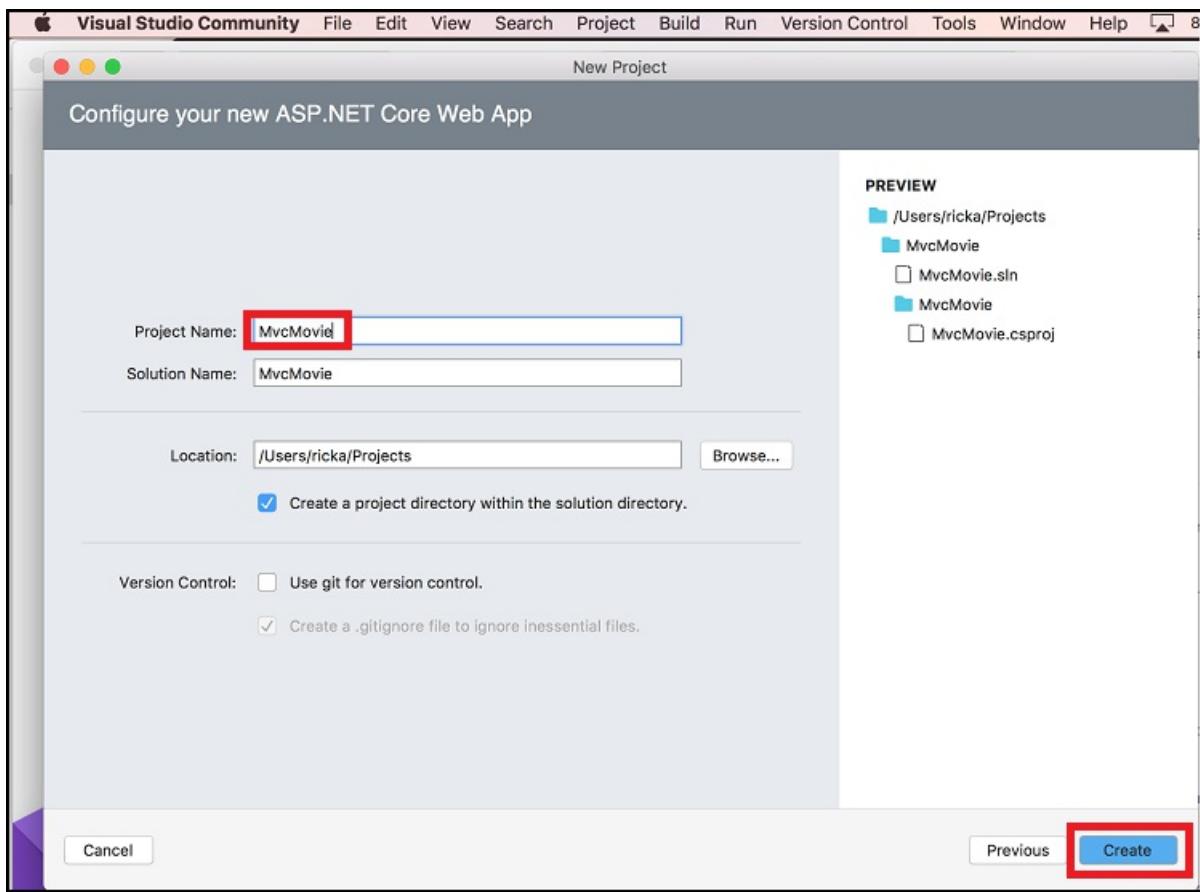

From Visual Studio, select **File > New Solution**.

Select .NET Core App > ASP.NET Core > Web App > Next.

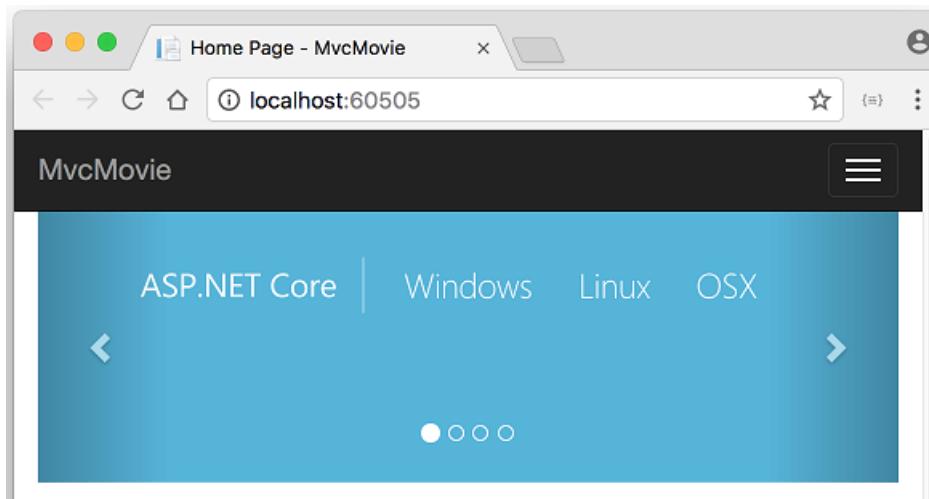

Name the project **MvcMovie**, and then select **Create**.

## Launch the app

In Visual Studio, select **Run > Start Without Debugging** to launch the app. Visual Studio starts **Kestrel**, launches a browser, and navigates to `http://localhost:port`, where *port* is a randomly chosen port number.

## Application uses

- Sample pages using ASP.NET Core MVC
- [Bower](#) for managing client-side libraries
- Theming using [Bootstrap](#)

## How to

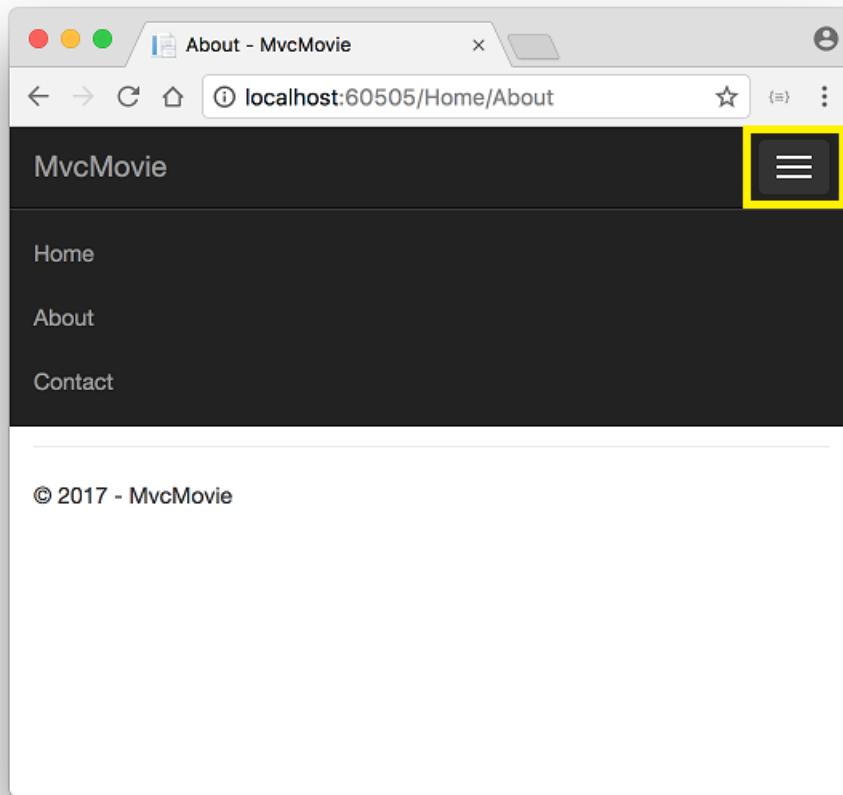

- [Add a Controller and View](#)
- [Manage User Secrets using Secret Manager](#).
- [Use logging to log a message](#).
- [Add packages using NuGet](#).
- [Add client packages using Bower](#).

- The address bar shows `localhost:port#` and not something like `example.com`. That's because `localhost` is the

standard hostname for your local computer. When Visual Studio creates a web project, a random port is used for the web server. When you run the app, you'll see a different port number.

- You can launch the app in debug or non-debug mode from the **Run** menu.

The default template gives you **Home**, **About** and **Contact** links. The browser image above doesn't show these links. Depending on the size of your browser, you might need to click the navigation icon to show them.

In the next part of this tutorial, you learn about MVC and start writing some code.

NEXT

# Add a controller to an ASP.NET Core MVC app with Visual Studio for Mac

6/21/2018 • 5 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

The Model-View-Controller (MVC) architectural pattern separates an app into three main components: **Model**, **View**, and **Controller**. The MVC pattern helps you create apps that are more testable and easier to update than traditional monolithic apps. MVC-based apps contain:

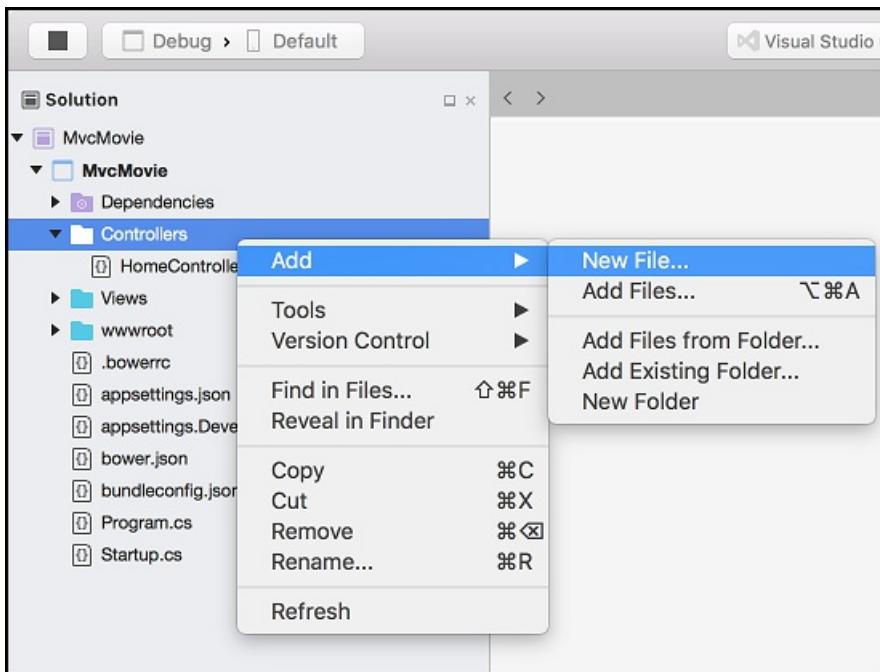

- **Models:** Classes that represent the data of the app. The model classes use validation logic to enforce business rules for that data. Typically, model objects retrieve and store model state in a database. In this tutorial, a `Movie` model retrieves movie data from a database, provides it to the view or updates it. Updated data is written to a database.
- **Views:** Views are the components that display the app's user interface (UI). Generally, this UI displays the model data.
- **Controllers:** Classes that handle browser requests. They retrieve model data and call view templates that return a response. In an MVC app, the view only displays information; the controller handles and responds to user input and interaction. For example, the controller handles route data and query-string values, and passes these values to the model. The model might use these values to query the database. For example, `http://localhost:1234/Home/About` has route data of `Home` (the controller) and `About` (the action method to call on the home controller). `http://localhost:1234/Movies/Edit/5` is a request to edit the movie with ID=5 using the movie controller. We'll talk about route data later in the tutorial.

The MVC pattern helps you create apps that separate the different aspects of the app (input logic, business logic, and UI logic), while providing a loose coupling between these elements. The pattern specifies where each kind of logic should be located in the app. The UI logic belongs in the view. Input logic belongs in the controller. Business logic belongs in the model. This separation helps you manage complexity when you build an app, because it enables you to work on one aspect of the implementation at a time without impacting the code of another. For example, you can work on the view code without depending on the business logic code.

We cover these concepts in this tutorial series and show you how to use them to build a movie app. The MVC project contains folders for the *Controllers* and *Views*.

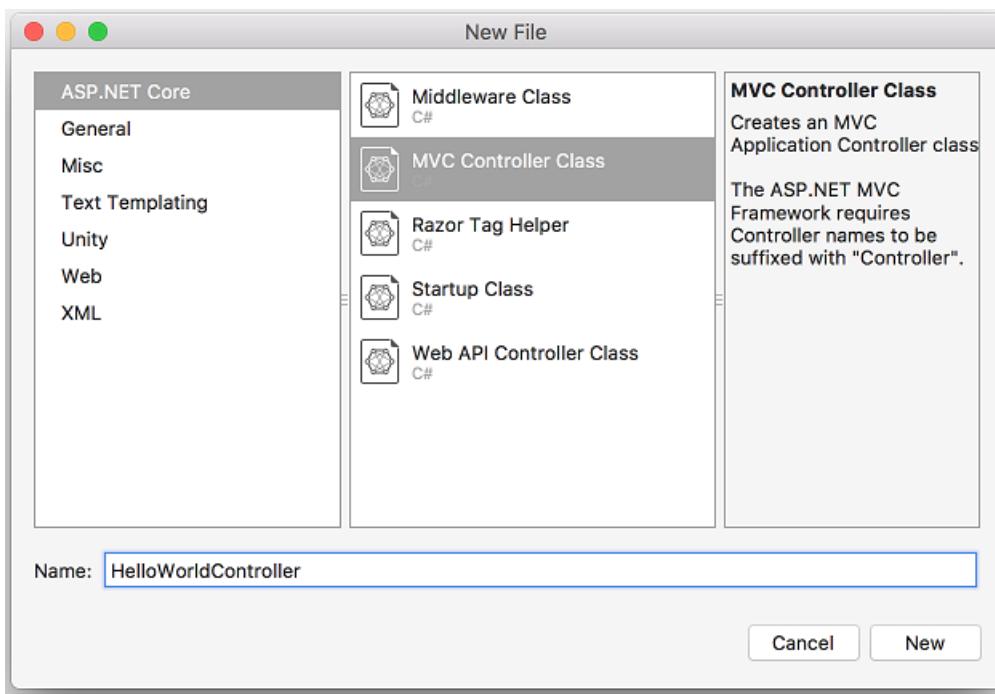

## Add a controller

In **Solution Explorer**, right-click **Controllers** > **Add** > **New File**.

Select **ASP.NET Core** and **MVC Controller Class**.

Name the controller **HelloWorldController**.

Replace the contents of *Controllers/HelloWorldController.cs* with the following:

```

using Microsoft.AspNetCore.Mvc;
using System.Text.Encodings.Web;

namespace MvcMovie.Controllers
{
    public class HelloWorldController : Controller
    {
        //
        // GET: /HelloWorld/

        public string Index()
        {
            return "This is my default action...";
        }

        //
        // GET: /HelloWorld/Welcome/

        public string Welcome()
        {
            return "This is the Welcome action method...";
        }
    }
}

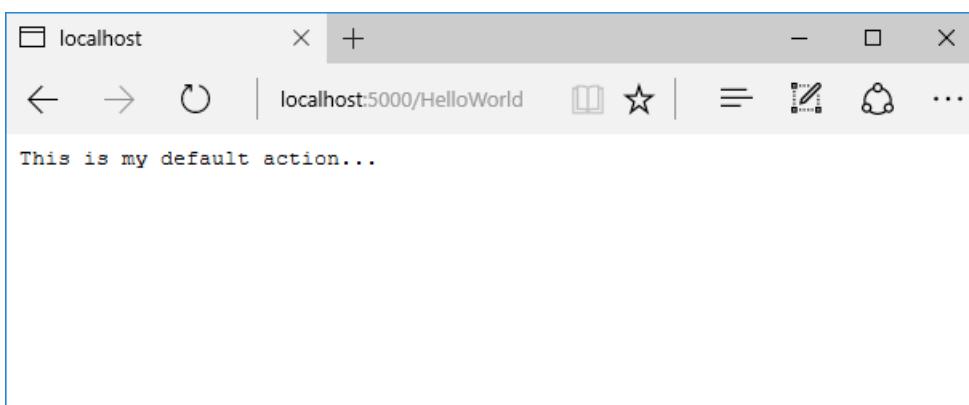

```

Every `public` method in a controller is callable as an HTTP endpoint. In the sample above, both methods return a string. Note the comments preceding each method.

An HTTP endpoint is a targetable URL in the web application, such as `http://localhost:1234/HelloWorld`, and combines the protocol used: `HTTP`, the network location of the web server (including the TCP port): `localhost:1234` and the target URI `HelloWorld`.

The first comment states this is an `HTTP GET` method that's invoked by appending `/HelloWorld/` to the base URL. The second comment specifies an `HTTP GET` method that's invoked by appending `/HelloWorld/Welcome/` to the URL. Later on in the tutorial you'll use the scaffolding engine to generate `HTTP POST` methods.

Run the app in non-debug mode and append "HelloWorld" to the path in the address bar. The `Index` method returns a string.

MVC invokes controller classes (and the action methods within them) depending on the incoming URL. The default [URL routing logic](#) used by MVC uses a format like this to determine what code to invoke:

`/[Controller]/[ActionName]/[Parameters]`

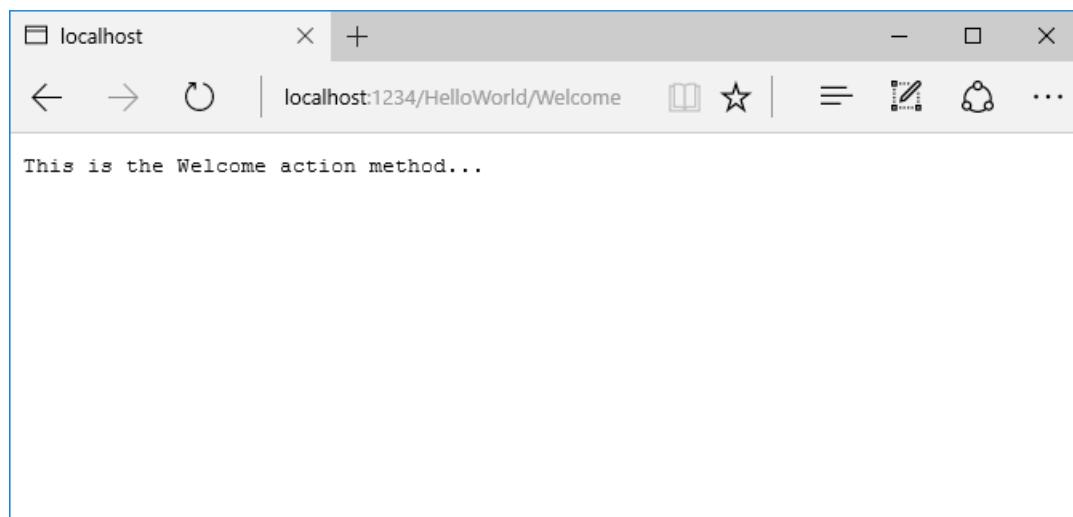

You set the format for routing in the `Configure` method in `Startup.cs` file.

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

When you run the app and don't supply any URL segments, it defaults to the "Home" controller and the "Index" method specified in the template line highlighted above.

The first URL segment determines the controller class to run. So `localhost:xxxx/HelloWorld` maps to the `HelloWorldController` class. The second part of the URL segment determines the action method on the class. So `localhost:xxxx/HelloWorld/Index` would cause the `Index` method of the `HelloWorldController` class to run. Notice that you only had to browse to `localhost:xxxx/HelloWorld` and the `Index` method was called by default. This is because `Index` is the default method that will be called on a controller if a method name isn't explicitly specified. The third part of the URL segment (`id`) is for route data. You'll see route data later on in this tutorial.

Browse to `http://localhost:xxxx/HelloWorld/Welcome`. The `Welcome` method runs and returns the string "This is the Welcome action method...". For this URL, the controller is `HelloWorld` and `Welcome` is the action method. You haven't used the `[Parameters]` part of the URL yet.

Modify the code to pass some parameter information from the URL to the controller. For example, `/HelloWorld/Welcome?name=Rick&numtimes=4`. Change the `Welcome` method to include two parameters as shown in the following code.

```
// GET: /HelloWorld/Welcome/
// Requires using System.Text.Encodings.Web;
public string Welcome(string name, int numTimes = 1)
{
    return HtmlEncoder.Default.Encode($"Hello {name}, NumTimes is: {numTimes}");
}
```

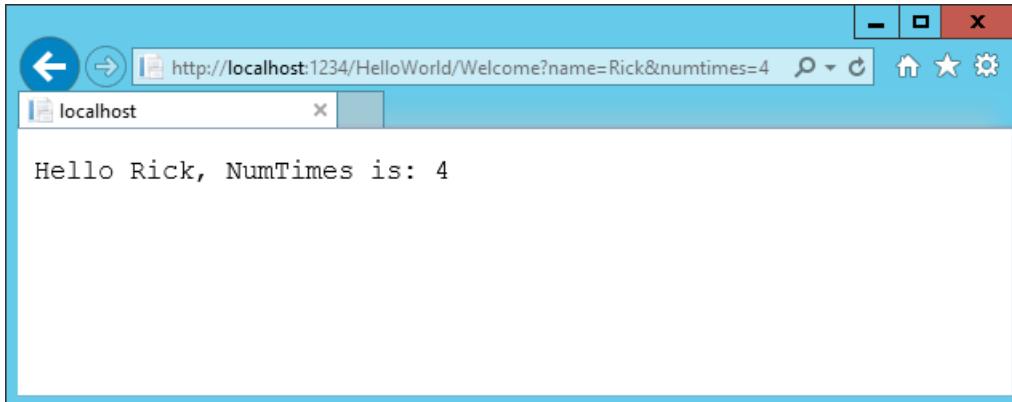

The preceding code:

- Uses the C# optional-parameter feature to indicate that the `numTimes` parameter defaults to 1 if no value is passed for that parameter.
- Uses `HtmlEncoder.Default.Encode` to protect the app from malicious input (namely JavaScript).
- Uses [Interpolated Strings](#).

Run your app and browse to:

```
http://localhost:xxxx/HelloWorld/Welcome?name=Rick&numtimes=4
```

(Replace xxxx with your port number.) You can try different values for `name` and `numtimes` in the URL. The MVC [model binding](#) system automatically maps the named parameters from the query string in the address bar to parameters in your method. See [Model Binding](#) for more information.

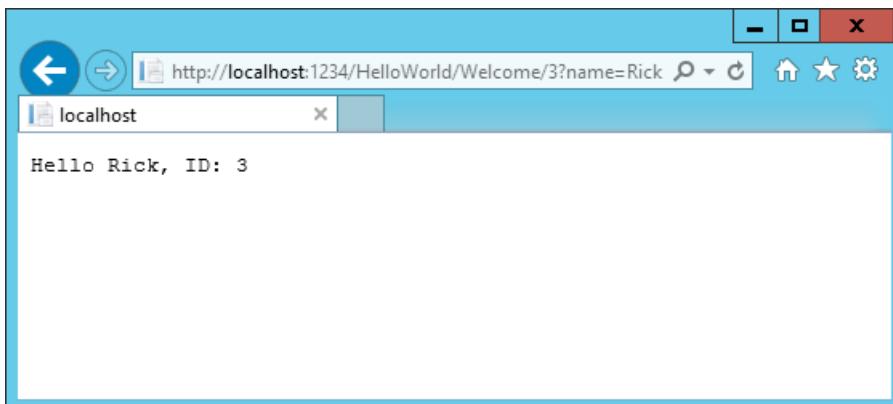

In the image above, the URL segment (`Parameters`) isn't used, the `name` and `numTimes` parameters are passed as [query strings](#). The `?` (question mark) in the above URL is a separator, and the query strings follow. The `&` character separates query strings.

Replace the `Welcome` method with the following code:

```
public string Welcome(string name, int ID = 1)
{
    return HtmlEncoder.Default.Encode($"Hello {name}, ID: {ID}");
}
```

Run the app and enter the following URL: `http://localhost:xxx/HelloWorld/Welcome/3?name=Rick`

This time the third URL segment matched the route parameter `id`. The `Welcome` method contains a parameter `id` that matched the URL template in the `MapRoute` method. The trailing `?` (in `id?`) indicates the `id` parameter is optional.

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

In these examples the controller has been doing the "VC" portion of MVC - that is, the view and controller work. The controller is returning HTML directly. Generally you don't want controllers returning HTML directly, since that becomes very cumbersome to code and maintain. Instead you typically use a separate Razor view template file to

help generate the HTML response. You do that in the next tutorial.

[PREVIOUS](#)

[NEXT](#)

# Add a view to an ASP.NET Core MVC app

6/21/2018 • 8 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section you modify the `HelloWorldController` class to use Razor view template files to cleanly encapsulate the process of generating HTML responses to a client.

You create a view template file using Razor. Razor-based view templates have a `.cshtml` file extension. They provide an elegant way to create HTML output using C#.

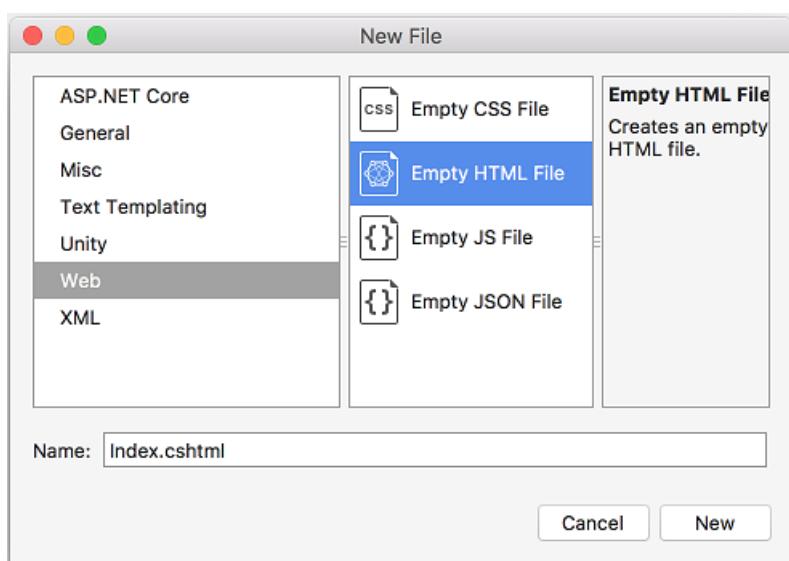

Currently the `Index` method returns a string with a message that's hard-coded in the controller class. In the `HelloWorldController` class, replace the `Index` method with the following code:

```
public IActionResult Index()
{
    return View();
}
```

The preceding code returns a `View` object. It uses a view template to generate an HTML response to the browser. Controller methods (also known as action methods) such as the `Index` method above, generally return an `IActionResult` (or a class derived from `ActionResult`), not a type like `string`.

## Add a view

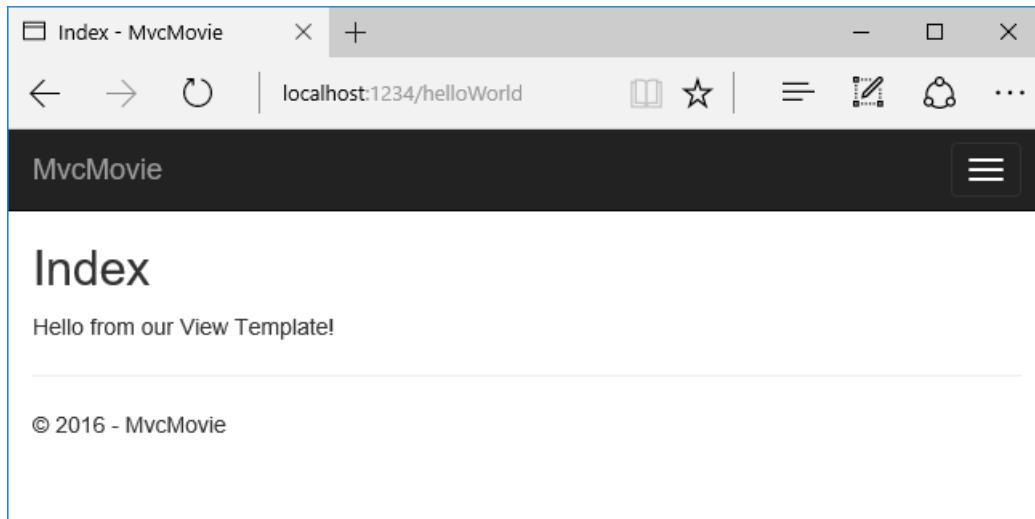

- Right click on the `Views` folder, and then **Add > New Folder** and name the folder `HelloWorld`.
- Right click on the `Views/HelloWorld` folder, and then **Add > New File**.
- In the **New File** dialog:
  - Select **Web** in the left pane.
  - Select **Empty HTML file** in the center pane.
  - Type `Index.cshtml` in the **Name** box.
  - Select **New**.

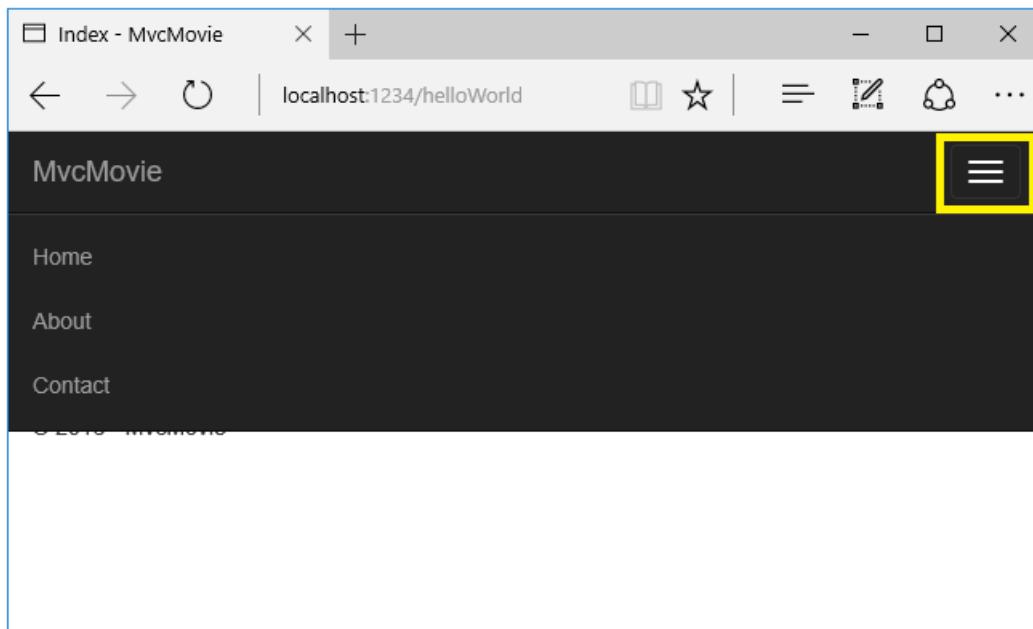

Replace the contents of the `Views/HelloWorld/Index.cshtml` Razor view file with the following:

```
@{  
    ViewData["Title"] = "Index";  
}  
  
<h2>Index</h2>  
  
<p>Hello from our View Template!</p>
```

Navigate to `http://localhost:xxxx/HelloWorld`. The `Index` method in the `HelloWorldController` didn't do much; it ran the statement `return View();`, which specified that the method should use a view template file to render a response to the browser. Because you didn't explicitly specify the name of the view template file, MVC defaulted to using the `Index.cshtml` view file in the `/Views/HelloWorld` folder. The image below shows the string "Hello from our View Template!" hard-coded in the view.

If your browser window is small (for example on a mobile device), you might need to toggle (tap) the [Bootstrap navigation button](#) in the upper right to see the **Home**, **About**, and **Contact** links.

## Changing views and layout pages

Tap the menu links (**MvcMovie**, **Home**, **About**). Each page shows the same menu layout. The menu layout is implemented in the `Views/Shared/_Layout.cshtml` file. Open the `Views/Shared/_Layout.cshtml` file.

Layout templates allow you to specify the HTML container layout of your site in one place and then apply it across multiple pages in your site. Find the `@RenderBody()` line. `RenderBody` is a placeholder where all the view-specific pages you create show up, *wrapped* in the layout page. For example, if you select the **About** link, the **Views/Home/About.cshtml** view is rendered inside the `RenderBody` method.

## Change the title and menu link in the layout file

In the title element, change `MvcMovie` to `Movie App`. Change the anchor text in the layout template from `MvcMovie` to `Movie App` and the controller from `Home` to `Movies` as highlighted below:

```
@inject Microsoft.ApplicationInsights.AspNetCore.JavaScriptSnippet JavaScriptSnippet
<!DOCTYPE html>
<html>
<head>
    <meta charset="utf-8" />
    <meta name="viewport" content="width=device-width, initial-scale=1.0" />
    <title>@ViewData["Title"] - Movie App</title>

    <environment names="Development">
        <link rel="stylesheet" href="~/lib/bootstrap/dist/css/bootstrap.css" />
        <link rel="stylesheet" href="~/css/site.css" />
    </environment>
    <environment names="Staging,Production">
        <link rel="stylesheet" href="https://ajax.aspnetcdn.com/ajax/bootstrap/3.3.7/css/bootstrap.min.css"
              asp-fallback-href="~/lib/bootstrap/dist/css/bootstrap.min.css"

### WARNING

We haven't implemented the `Movies` controller yet, so if you click on that link, you'll get a 404 (Not found) error.

Save your changes and tap the **About** link. Notice how the title on the browser tab now displays **About - Movie App** instead of **About - Mvc Movie**:

Tap the **Contact** link and notice that the title and anchor text also display **Movie App**. We were able to make the change once in the layout template and have all pages on the site reflect the new link text and new title.

Examine the *Views/\_ViewStart.cshtml* file:

```
@{  
    Layout = "_Layout";  
}
```

The *Views/\_ViewStart.cshtml* file brings in the *Views/Shared/\_Layout.cshtml* file to each view. You can use the `Layout` property to set a different layout view, or set it to `null` so no layout file will be used.

Change the title of the `Index` view.

Open *Views/HelloWorld/Index.cshtml*. There are two places to make a change:

- The text that appears in the title of the browser.
- The secondary header (`<h2>` element).

You'll make them slightly different so you can see which bit of code changes which part of the app.

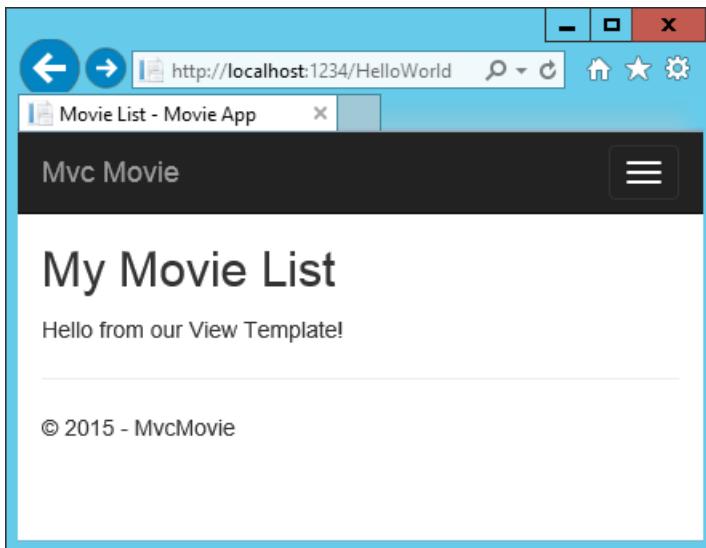

```
@{  
    ViewData["Title"] = "Movie List";  
}  
  
<h2>My Movie List</h2>  
  
<p>Hello from our View Template!</p>
```

`ViewData["Title"] = "Movie List";` in the code above sets the `Title` property of the `ViewData` dictionary to "Movie List". The `Title` property is used in the `<title>` HTML element in the layout page:

```
<title>@ViewData["Title"] - Movie App</title>
```

Save your change and navigate to `http://localhost:xxxx/HelloWorld`. Notice that the browser title, the primary heading, and the secondary headings have changed. (If you don't see changes in the browser, you might be viewing cached content. Press **Ctrl+F5** in your browser to force the response from the server to be loaded.) The browser title is created with `ViewData["Title"]` we set in the *Index.cshtml* view template and the additional "-Movie App" added in the layout file.

Also notice how the content in the *Index.cshtml* view template was merged with the *Views/Shared/\_Layout.cshtml* view template and a single HTML response was sent to the browser. Layout templates make it really easy to make changes that apply across all of the pages in your application. To learn more see [Layout](#).

Our little bit of "data" (in this case the "Hello from our View Template!" message) is hard-coded, though. The MVC application has a "V" (view) and you've got a "C" (controller), but no "M" (model) yet.

## Passing Data from the Controller to the View

Controller actions are invoked in response to an incoming URL request. A controller class is where you write the code that handles the incoming browser requests. The controller retrieves data from a data source and decides what type of response to send back to the browser. View templates can be used from a controller to generate and format an HTML response to the browser.

Controllers are responsible for providing the data required in order for a view template to render a response. A best practice: View templates should **not** perform business logic or interact with a database directly. Rather, a view template should work only with the data that's provided to it by the controller. Maintaining this "separation of concerns" helps keep your code clean, testable, and maintainable.

Currently, the `Welcome` method in the `HelloWorldController` class takes a `name` and a `ID` parameter and then outputs the values directly to the browser. Rather than have the controller render this response as a string, change the controller to use a view template instead. The view template generates a dynamic response, which means that appropriate bits of data must be passed from the controller to the view in order to generate the response. Do this by having the controller put the dynamic data (parameters) that the view template needs in a `ViewData` dictionary that the view template can then access.

Return to the `HelloWorldController.cs` file and change the `Welcome` method to add a `Message` and `NumTimes` value to the `ViewData` dictionary. The `ViewData` dictionary is a dynamic object, which means you can put whatever you want in to it; the `ViewData` object has no defined properties until you put something inside it. The [MVC model binding system](#) automatically maps the named parameters (`name` and `numTimes`) from the query string in the address bar to parameters in your method. The complete `HelloWorldController.cs` file looks like this:

```

using Microsoft.AspNetCore.Mvc;
using System.Text.Encodings.Web;

namespace MvcMovie.Controllers
{
    public class HelloWorldController : Controller
    {
        public IActionResult Index()
        {
            return View();
        }

        public IActionResult Welcome(string name, int numTimes = 1)
        {
            ViewData["Message"] = "Hello " + name;
            ViewData["NumTimes"] = numTimes;

            return View();
        }
    }
}

```

The `ViewData` dictionary object contains data that will be passed to the view.

Create a Welcome view template named `Views/HelloWorld/Welcome.cshtml`.

You'll create a loop in the `Welcome.cshtml` view template that displays "Hello" `NumTimes`. Replace the contents of `Views/HelloWorld/Welcome.cshtml` with the following:

```

@{
    ViewData["Title"] = "Welcome";
}

<h2>Welcome</h2>

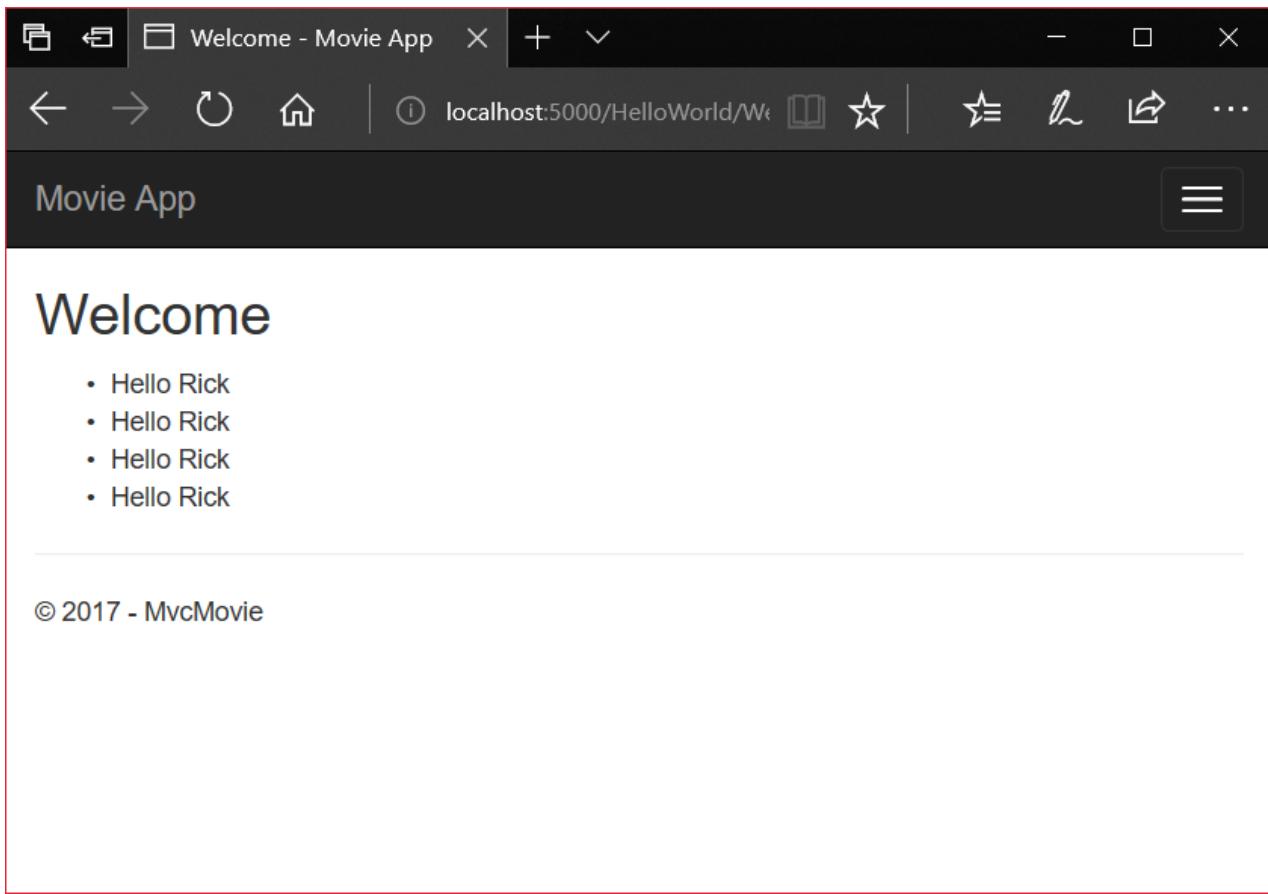

<ul>
    @for (int i = 0; i < (int)ViewData["NumTimes"]; i++)
    {
        <li>@ViewData["Message"]</li>
    }
</ul>

```

Save your changes and browse to the following URL:

`http://localhost:xxxx/HelloWorld/Welcome?name=Rick&numtimes=4`

Data is taken from the URL and passed to the controller using the [MVC model binder](#). The controller packages the data into a `ViewData` dictionary and passes that object to the view. The view then renders the data as HTML to the browser.

In the sample above, we used the `ViewData` dictionary to pass data from the controller to a view. Later in the tutorial, we will use a view model to pass data from a controller to a view. The view model approach to passing data is generally much preferred over the `ViewData` dictionary approach. See [ViewModel vs ViewData vs ViewBag vs TempData vs Session in MVC](#) for more information.

Well, that was a kind of an "M" for model, but not the database kind. Let's take what we've learned and create a database of movies.

[PREVIOUS](#) [NEXT](#)

# Add a model to an ASP.NET Core MVC app

6/26/2018 • 5 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Tom Dykstra](#)

In this section, you'll add some classes for managing movies in a database. These classes will be the "**Model**" part of the **MVC** app.

You use these classes with [Entity Framework Core](#) (EF Core) to work with a database. EF Core is an object-relational mapping (ORM) framework that simplifies the data access code that you have to write. [EF Core supports many database engines](#).

The model classes you'll create are known as POCO classes (from "plain-old CLR objects") because they don't have any dependency on EF Core. They just define the properties of the data that will be stored in the database.

In this tutorial you'll write the model classes first, and EF Core will create the database. An alternate approach not covered here is to generate model classes from an already-existing database. For information about that approach, see [ASP.NET Core - Existing Database](#).

## Add a data model class

- Right-click the *Models* folder, and then select **Add > New File**.
- In the **New File** dialog:
  - Select **General** in the left pane.
  - Select **Empty Class** in the center pain.
  - Name the class **Movie** and select **New**.

Add the following properties to the `Movie` class:

```
using System;

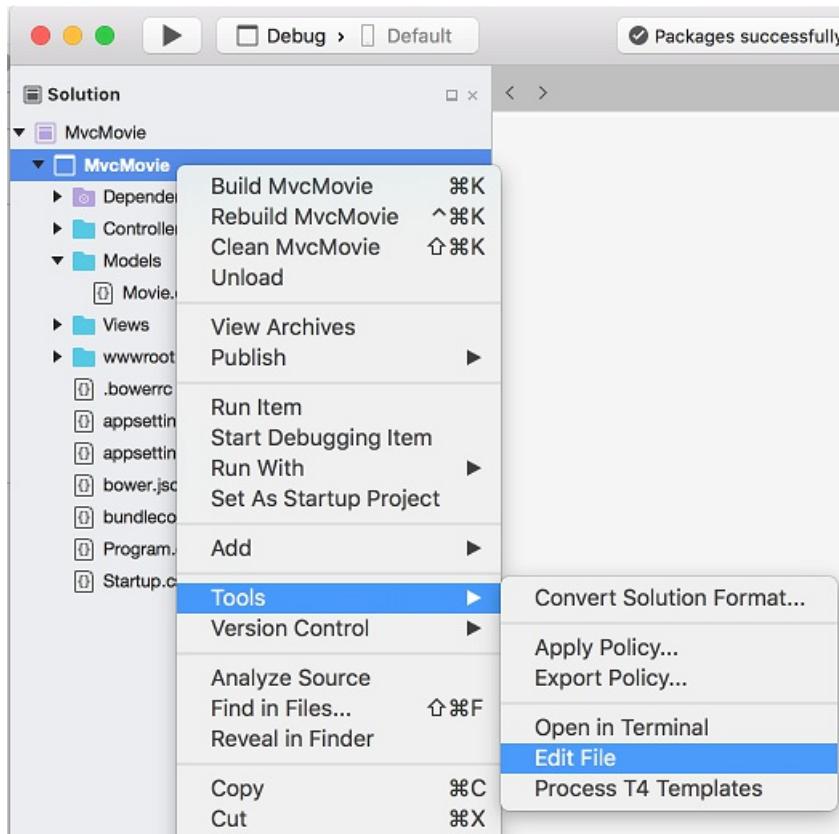

namespace MvcMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

The `ID` field is required by the database for the primary key.

Build the project to verify you don't have any errors. You now have a **Model** in your **MVC** app.

## Prepare the project for scaffolding

- Right click on the project file, and then select **Tools > Edit File**.

- Add the following highlighted NuGet packages to the *MvcMovie.csproj* file:

```
<Project Sdk="Microsoft.NET.Sdk.Web">
<PropertyGroup>
    <TargetFramework>netcoreapp2.0</TargetFramework>
</PropertyGroup>
<ItemGroup>
    <PackageReference Include="Microsoft.AspNetCore.All" Version="2.0.0" />
    <PackageReference Include="Microsoft.VisualStudio.Web.CodeGeneration.Design" Version="2.0.0" />
</ItemGroup>
<ItemGroup>
    <DotNetCliToolReference Include="Microsoft.EntityFrameworkCore.Tools.DotNet" Version="2.0.0" />
    <DotNetCliToolReference Include="Microsoft.VisualStudio.Web.CodeGeneration.Tools" Version="2.0.0" />
</ItemGroup>
</Project>
```

- Save the file.
- Create a *Models/MvcMovieContext.cs* file and add the following `MvcMovieContext` class:

```
using Microsoft.EntityFrameworkCore;

namespace MvcMovie.Models
{
    public class MvcMovieContext : DbContext
    {
        public MvcMovieContext (DbContextOptions<MvcMovieContext> options)
            : base(options)
        {
        }

        public DbSet<MvcMovie.Models.Movie> Movie { get; set; }
    }
}
```

- Open the *Startup.cs* file and add two usings:

```
using Microsoft.EntityFrameworkCore;
using MvcMovie.Models;

namespace MvcMovie
{
    public class Startup
    {
```

- Add the database context to the *Startup.cs* file:

```
public void ConfigureServices(IServiceCollection services)
{
    // Add framework services.
    services.AddMvc();

    services.AddDbContext<MvcMovieContext>(options =>
        options.UseSqlite("Data Source=MvcMovie.db"));

}
```

This tells Entity Framework which model classes are included in the data model. You're defining one *entity set* of Movie objects, which will be represented in the database as a Movie table.

- Build the project to verify there are no errors.

## Scaffold the MovieController

Open a terminal window in the project folder and run the following commands:

```
dotnet restore
dotnet aspnet-codegenerator controller -name MoviesController -m Movie -dc MvcMovieContext --
relativeFolderPath Controllers --useDefaultLayout --referenceScriptLibraries
```

If you get the error `No executable found matching command "dotnet-aspnet-codegenerator"`, verify :

- You are in the project directory. The project directory has the *Program.cs*, *Startup.cs* and *.csproj* files.
- Your dotnet version is 1.1 or higher. Run `dotnet` to get the version.
- You have added the `<DotNetCliToolReference>` element to the [MvcMovie.csproj file](#).

The scaffolding engine creates the following:

- A movies controller (*Controllers/MoviesController.cs*)
- Razor view files for Create, Delete, Details, Edit and Index pages (*Views/Movies/\*.cshtml*)

The automatic creation of **CRUD** (create, read, update, and delete) action methods and views is known as *scaffolding*. You'll soon have a fully functional web application that lets you manage a movie database.

### Add the files to Visual Studio

- Add the *MovieController.cs* file to the Visual Studio project:
  - Right-click on the *Controllers* folder and select **Add > Add Files**.
  - Select the *MovieController.cs* file.
- Add the *Movies* folder and views:
  - Right-click on the *Views* folder and select **Add > Add Existing Folder**.

- Navigate to the *Views* folder, select *Views\Movies*, and then select **Open**.
- In the **Select files to add from Movies** dialog, select **Include All**, and then **OK**.

## Perform initial migration

From the command line, run the following .NET Core CLI commands:

```
dotnet ef migrations add InitialCreate  
dotnet ef database update
```

The `dotnet ef migrations add InitialCreate` command generates code to create the initial database schema. The schema is based on the model specified in the `DbContext` (In the *Models/MvcMovieContext.cs* file). The `Initial` argument is used to name the migrations. You can use any name, but by convention you choose a name that describes the migration. See [Introduction to migrations](#) for more information.

The `dotnet ef database update` command runs the `Up` method in the *Migrations/<time-stamp>\_InitialCreate.cs* file, which creates the database.

## Test the app

- Run the app and tap the **Mvc Movie** link.
- Tap the **Create New** link and create a movie.

The screenshot shows a browser window titled "Create - Movie App" with the URL "localhost:1234/Movies/". The page is titled "MvcMovie" and has a header "Create". The form is for creating a "Movie" with fields: "Title" (Conan), "Release Date" (3/3/2017), "Genre" (Comedy), and "Price" (1.99). A "Create" button is at the bottom.

- You may not be able to enter decimal points or commas in the `Price` field. To support [jQuery validation](#) for non-English locales that use a comma (",") for a decimal point, and non US-English date formats, you must take steps to globalize your app. See <https://github.com/aspnet/Docs/issues/4076> and [Additional resources](#) for more information. For now, just enter whole numbers like 10.
- In some locales you need to specify the date format. See the highlighted code below.

```
using System;
using System.ComponentModel.DataAnnotations;

namespace MvcMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

We'll talk about `DataAnnotations` later in the tutorial.

Tapping **Create** causes the form to be posted to the server, where the movie information is saved in a database. The app redirects to the /Movies URL, where the newly created movie information is displayed.

Index

Create New

Title	Release Date	Genre	Price
Conan	3/3/2017	Comedy	\$1.99

© 2017 - MvcMovie

Create a couple more movie entries. Try the **Edit**, **Details**, and **Delete** links, which are all functional.

You now have a database and pages to display, edit, update and delete data. In the next tutorial, we'll work with the database.

[NEXT WORKING WITH](#)

[SQL](#)

# Work with SQLite in an ASP.NET Core MVC app

6/26/2018 • 2 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

The `MvcMovieContext` object handles the task of connecting to the database and mapping `Movie` objects to database records. The database context is registered with the [Dependency Injection](#) container in the `ConfigureServices` method in the `Startup.cs` file:

```
public void ConfigureServices(IServiceCollection services)
{
    // Add framework services.
    services.AddMvc();

    services.AddDbContext<MvcMovieContext>(options =>
        options.UseSqlite("Data Source=MvcMovie.db"));

}
```

## SQLite

The [SQLite](#) website states:

SQLite is a self-contained, high-reliability, embedded, full-featured, public-domain, SQL database engine.  
SQLite is the most used database engine in the world.

There are many third party tools you can download to manage and view a SQLite database. The image below is from [DB Browser for SQLite](#). If you have a favorite SQLite tool, leave a comment on what you like about it.

The screenshot shows the DB Browser for SQLite interface with the following details:

- Toolbar:** New Database, Open Database, Write Changes, Revert Changes.
- Tab Bar:** Database Structure (selected), Browse Data, Edit Pragmas, Execute SQL.
- Sub-Toolbar:** Create Table, Create Index, Modify Table, Delete Table.
- Table List:**
  - Tables (3):**
    - Movie:** Contains columns ID (INTEGER), Genre (TEXT), Price (TEXT), ReleaseDate (TEXT), and Title (TEXT).
    - \_\_EFMigrationsHistory:** Contains column MigrationId (TEXT).
    - sqlite\_sequence:** Contains columns name (TEXT) and seq (INTEGER).
  - Indices (1):** sqlite\_autoindex\_\_EFMigrationsHis...
  - Views (0):** None.
  - Triggers (0):** None.
- Bottom Right:** UTF-8 encoding indicator.

## Seed the database

Create a new class named `SeedData` in the *Models* folder. Replace the generated code with the following:

```

using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using System;
using System.Linq;

namespace MvcMovie.Models
{
    public static class SeedData
    {
        public static void Initialize(IServiceProvider serviceProvider)
        {
            using (var context = new MvcMovieContext(
                serviceProvider.GetRequiredService<DbContextOptions<MvcMovieContext>>()))
            {
                // Look for any movies.
                if (context.Movie.Any())
                {
                    return; // DB has been seeded
                }

                context.Movie.AddRange(
                    new Movie
                    {
                        Title = "When Harry Met Sally",
                        ReleaseDate = DateTime.Parse("1989-1-11"),
                        Genre = "Romantic Comedy",
                        Price = 7.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters ",
                        ReleaseDate = DateTime.Parse("1984-3-13"),
                        Genre = "Comedy",
                        Price = 8.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters 2",
                        ReleaseDate = DateTime.Parse("1986-2-23"),
                        Genre = "Comedy",
                        Price = 9.99M
                    },
                    new Movie
                    {
                        Title = "Rio Bravo",
                        ReleaseDate = DateTime.Parse("1959-4-15"),
                        Genre = "Western",
                        Price = 3.99M
                    }
                );
                context.SaveChanges();
            }
        }
    }
}

```

If there are any movies in the DB, the seed initializer returns.

```
if (context.Movie.Any())
{
    return; // DB has been seeded.
}
```

## Add the seed initializer

Add the seed initializer to the `Main` method in the `Program.cs` file:

```
using Microsoft.AspNetCore;
using Microsoft.AspNetCore.Hosting;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Logging;
using System;
using Microsoft.EntityFrameworkCore;
using MvcMovie.Models;
using MvcMovie;

namespace MvcMovie
{
    public class Program
    {
        public static void Main(string[] args)
        {
            var host = CreateWebHostBuilder(args).Build();

            using (var scope = host.Services.CreateScope())
            {
                var services = scope.ServiceProvider;

                try
                {
                    var context = services.GetRequiredService<MvcMovieContext>();
                    context.Database.Migrate();
                    SeedData.Initialize(services);
                }
                catch (Exception ex)
                {
                    var logger = services.GetRequiredService<ILogger<Program>>();
                    logger.LogError(ex, "An error occurred seeding the DB.");
                }
            }

            host.Run();
        }

        public static IWebHostBuilder CreateWebHostBuilder(string[] args) =>
            WebHost.CreateDefaultBuilder(args)
                .UseStartup<Startup>();
    }
}
```

```

using Microsoft.AspNetCore;
using Microsoft.AspNetCore.Hosting;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Logging;
using MvcMovie.Models;
using System;

namespace MvcMovie
{
    public class Program
    {
        public static void Main(string[] args)
        {
            var host = BuildWebHost(args);

            using (var scope = host.Services.CreateScope())
            {
                var services = scope.ServiceProvider;

                try
                {
                    // Requires using MvcMovie.Models;
                    SeedData.Initialize(services);
                }
                catch (Exception ex)
                {
                    var logger = services.GetRequiredService<ILogger<Program>>();
                    logger.LogError(ex, "An error occurred seeding the DB.");
                }
            }

            host.Run();
        }

        public static IWebHost BuildWebHost(string[] args) =>
            WebHost.CreateDefaultBuilder(args)
                .UseStartup<Startup>()
                .Build();
    }
}

```

## Test the app

Delete all the records in the DB (So the seed method will run). Stop and start the app to seed the database.

The app shows the seeded data.

A screenshot of a Microsoft Edge browser window. The title bar says "Ricka - Movie App". The address bar shows "localhost:5000/Movies". The main content area has a dark header with "MvcMovie" and a menu icon. Below it, a table lists four movies:

Title	ReleaseDate	Genre	Price	
When Harry Met Sally	1/11/1989 12:00:00 AM	Romantic Comedy	7.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Ghostbusters	3/13/1984 12:00:00 AM	Comedy	8.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Ghostbusters 2	2/23/1986 12:00:00 AM	Comedy	9.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Rio Bravo	4/15/1959 12:00:00 AM	Western	3.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

At the bottom left, it says "© 2017 - MvcMovie".

[NEXT - CONTROLLER METHODS AND  
VIEWS](#)

# Controller methods and views in an ASP.NET Core MVC app

6/21/2018 • 10 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

We have a good start to the movie app, but the presentation isn't ideal. We don't want to see the time (12:00:00 AM in the following image) and **ReleaseDate** should be two words.

The screenshot shows a browser window titled "Movie App" with the URL "localhost:5000/Movies". The page has a dark header with the text "MvcMovie" and a "Create New" button. Below the header is a table with four columns: "Title", "ReleaseDate", "Genre", and "Price". The table contains four rows of movie data:

Title	ReleaseDate	Genre	Price
When Harry Met Sally	1/11/1989 12:00:00 AM	Romantic Comedy	7.99
Ghostbusters	3/13/1984 12:00:00 AM	Comedy	8.99
Ghostbusters 2	2/23/1986 12:00:00 AM	Comedy	9.99
Rio Bravo	4/15/1959 12:00:00 AM	Western	3.99

Each row has "Edit | Details | Delete" links in the last column. At the bottom of the page, there is a copyright notice: "© 2017 - MvcMovie".

Open the *Models/Movie.cs* file and add the highlighted lines shown below:

```
using System;
using System.ComponentModel.DataAnnotations;

namespace MvcMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }

        [Display(Name = "Release Date")]
        [DataType(DataType.Date)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

Build and run the app.

We cover [DataAnnotations](#) in the next tutorial. The [Display](#) attribute specifies what to display for the name of a field (in this case "Release Date" instead of "ReleaseDate"). The [DataType](#) attribute specifies the type of the data (Date), so the time information stored in the field isn't displayed.

The `[Column(TypeName = "decimal(18, 2)")]` data annotation is required so Entity Framework Core can correctly map `Price` to currency in the database. For more information, see [Data Types](#).

Browse to the `Movies` controller and hold the mouse pointer over an **Edit** link to see the target URL.

Genre	Price	Release Date	Title	
Romantic Comedy	7.99	1/11/1989	When Harry Met Sally	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	8.99	3/13/1984	Ghostbusters	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	9.99	2/23/1986	Ghostbusters 2	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Western	3.99	4/15/1959	Rio Bravo	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

© 2016 - MvcMovie

<http://localhost:1234/Movies/Edit/5>

The **Edit**, **Details**, and **Delete** links are generated by the Core MVC Anchor Tag Helper in the `Views/Movies/Index.cshtml` file.

```
<a asp-action="Edit" asp-route-id="@item.ID">Edit</a> |
<a asp-action="Details" asp-route-id="@item.ID">Details</a> |
<a asp-action="Delete" asp-route-id="@item.ID">Delete</a>
</td>
</tr>
```

[Tag Helpers](#) enable server-side code to participate in creating and rendering HTML elements in Razor files. In the code above, the `AnchorTagHelper` dynamically generates the HTML `href` attribute value from the controller action method and route id. You use **View Source** from your favorite browser or use the developer tools to examine the generated markup. A portion of the generated HTML is shown below:

```
<td>
<a href="/Movies/Edit/4"> Edit </a> |
<a href="/Movies/Details/4"> Details </a> |
<a href="/Movies/Delete/4"> Delete </a>
</td>
```

Recall the format for [routing](#) set in the `Startup.cs` file:

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

ASP.NET Core translates `http://localhost:1234/Movies/Edit/4` into a request to the `Edit` action method of the `Movies` controller with the parameter `Id` of 4. (Controller methods are also known as action methods.)

[Tag Helpers](#) are one of the most popular new features in ASP.NET Core. See [Additional resources](#) for more information.

Open the `Movies` controller and examine the two `Edit` action methods. The following code shows the `HTTP GET Edit` method, which fetches the movie and populates the edit form generated by the `Edit.cshtml` Razor file.

```
// GET: Movies/Edit/5
public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie.FindAsync(id);
    if (movie == null)
    {
        return NotFound();
    }
    return View(movie);
}
```

The following code shows the `HTTP POST Edit` method, which processes the posted movie values:

```

// POST: Movies/Edit/5
// To protect from overposting attacks, please enable the specific properties you want to bind to, for
// more details see http://go.microsoft.com/fwlink/?LinkId=317598.
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction("Index");
    }
    return View(movie);
}

```

```

// GET: Movies/Edit/5
public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }
    return View(movie);
}

```

The following code shows the `HTTP POST Edit` method, which processes the posted movie values:

```
// POST: Movies/Edit/5
// To protect from overposting attacks, please enable the specific properties you want to bind to, for
// more details see http://go.microsoft.com/fwlink/?LinkId=317598.
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction("Index");
    }
    return View(movie);
}
```

The `[Bind]` attribute is one way to protect against [over-posting](#). You should only include properties in the `[Bind]` attribute that you want to change. See [Protect your controller from over-posting](#) for more information.

[ViewModels](#) provide an alternative approach to prevent over-posting.

Notice the second `Edit` action method is preceded by the `[HttpPost]` attribute.

```
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction(nameof(Index));
    }
    return View(movie);
}
```

```

// POST: Movies/Edit/5
// To protect from overposting attacks, please enable the specific properties you want to bind to, for
// more details see http://go.microsoft.com/fwlink/?LinkId=317598.
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction("Index");
    }
    return View(movie);
}

```

The `[HttpPost]` attribute specifies that this `Edit` method can be invoked *only* for `POST` requests. You could apply the `[HttpGet]` attribute to the first edit method, but that's not necessary because `[HttpGet]` is the default.

The `[ValidateAntiForgeryToken]` attribute is used to [prevent forgery of a request](#) and is paired up with an anti-forgery token generated in the edit view file (`Views/Movies/Edit.cshtml`). The edit view file generates the anti-forgery token with the [Form Tag Helper](#).

```
<form asp-action="Edit">
```

The [Form Tag Helper](#) generates a hidden anti-forgery token that must match the `[ValidateAntiForgeryToken]` generated anti-forgery token in the `Edit` method of the Movies controller. For more information, see [Anti-Request Forgery](#).

The `[HttpGet Edit]` method takes the movie `ID` parameter, looks up the movie using the Entity Framework `SingleOrDefaultAsync` method, and returns the selected movie to the Edit view. If a movie cannot be found, `NotFound` (HTTP 404) is returned.

```
// GET: Movies/Edit/5
public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie.FindAsync(id);
    if (movie == null)
    {
        return NotFound();
    }
    return View(movie);
}
```

```
// GET: Movies/Edit/5
public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }
    return View(movie);
}
```

When the scaffolding system created the Edit view, it examined the `Movie` class and created code to render `<label>` and `<input>` elements for each property of the class. The following example shows the Edit view that was generated by the Visual Studio scaffolding system:

```

@model MvcMovie.Models.Movie

 @{
     ViewData["Title"] = "Edit";
 }

<h2>Edit</h2>

<form asp-action="Edit">
    <div class="form-horizontal">
        <h4>Movie</h4>
        <hr />
        <div asp-validation-summary="ModelOnly" class="text-danger"></div>
        <input type="hidden" asp-for="ID" />
        <div class="form-group">
            <label asp-for="Title" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Title" class="form-control" />
                <span asp-validation-for="Title" class="text-danger"></span>
            </div>
        </div>
        <div class="form-group">
            <label asp-for="ReleaseDate" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="ReleaseDate" class="form-control" />
                <span asp-validation-for="ReleaseDate" class="text-danger"></span>
            </div>
        </div>
        <div class="form-group">
            <label asp-for="Genre" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Genre" class="form-control" />
                <span asp-validation-for="Genre" class="text-danger"></span>
            </div>
        </div>
        <div class="form-group">
            <label asp-for="Price" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Price" class="form-control" />
                <span asp-validation-for="Price" class="text-danger"></span>
            </div>
        </div>
        <div class="form-group">
            <div class="col-md-offset-2 col-md-10">
                <input type="submit" value="Save" class="btn btn-default" />
            </div>
        </div>
    </div>
</form>

<div>
    <a asp-action="Index">Back to List</a>
</div>

@section Scripts {
    @{await Html.RenderPartialAsync("_ValidationScriptsPartial");}
}

```

Notice how the view template has a `@model MvcMovie.Models.Movie` statement at the top of the file.

`@model MvcMovie.Models.Movie` specifies that the view expects the model for the view template to be of type `Movie`.

The scaffolded code uses several Tag Helper methods to streamline the HTML markup. The - [Label Tag Helper](#) displays the name of the field ("Title", "ReleaseDate", "Genre", or "Price"). The [Input Tag Helper](#) renders an HTML `<input>` element. The [Validation Tag Helper](#) displays any validation messages associated with that property.

Run the application and navigate to the `/Movies` URL. Click an **Edit** link. In the browser, view the source for the page. The generated HTML for the `<form>` element is shown below.

```
<form action="/Movies/Edit/7" method="post">
    <div class="form-horizontal">
        <h4>Movie</h4>
        <hr />
        <div class="text-danger" />
        <input type="hidden" data-val="true" data-val-required="The ID field is required." id="ID" name="ID" value="7" />
        <div class="form-group">
            <label class="control-label col-md-2" for="Genre" />
            <div class="col-md-10">
                <input class="form-control" type="text" id="Genre" name="Genre" value="Western" />
                <span class="text-danger field-validation-valid" data-valmsg-for="Genre" data-valmsg-replace="true"></span>
            </div>
        </div>
        <div class="form-group">
            <label class="control-label col-md-2" for="Price" />
            <div class="col-md-10">
                <input class="form-control" type="text" data-val="true" data-val-number="The field Price must be a number." data-val-required="The Price field is required." id="Price" name="Price" value="3.99" />
                <span class="text-danger field-validation-valid" data-valmsg-for="Price" data-valmsg-replace="true"></span>
            </div>
        </div>
        <!-- Markup removed for brevity -->
        <div class="form-group">
            <div class="col-md-offset-2 col-md-10">
                <input type="submit" value="Save" class="btn btn-default" />
            </div>
        </div>
    </div>
    <input name="__RequestVerificationToken" type="hidden" value="CfDJ8Inyxp63fRFqUePGvuI5jGZsloJu1L7X9le1gy7NCI1SduCRx9jDQC1rV9pOTTmqUyXnJBXhmrjcUVDJyDUMm7-MF_9rK8aAZdRdl0ri7FmKVkRe_2v5LIHGKFcTjPrWPYnc9AdSbomki0SaTEg7RU" />
</form>
```

The `<input>` elements are in an `HTML <form>` element whose `action` attribute is set to post to the `/Movies/Edit/id` URL. The form data will be posted to the server when the `Save` button is clicked. The last line before the closing `</form>` element shows the hidden **XSRF** token generated by the [Form Tag Helper](#).

## Processing the POST Request

The following listing shows the `[HttpPost]` version of the `Edit` action method.

```
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction(nameof(Index));
    }
    return View(movie);
}
```

```

// POST: Movies/Edit/5
// To protect from overposting attacks, please enable the specific properties you want to bind to, for
// more details see http://go.microsoft.com/fwlink/?LinkId=317598.
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction("Index");
    }
    return View(movie);
}

```

The `[ValidateAntiForgeryToken]` attribute validates the hidden [XSRF](#) token generated by the anti-forgery token generator in the [Form Tag Helper](#)

The [model binding](#) system takes the posted form values and creates a `Movie` object that's passed as the `movie` parameter. The `ModelState.IsValid` method verifies that the data submitted in the form can be used to modify (edit or update) a `Movie` object. If the data is valid it's saved. The updated (edited) movie data is saved to the database by calling the `SaveChangesAsync` method of database context. After saving the data, the code redirects the user to the `Index` action method of the `MoviesController` class, which displays the movie collection, including the changes just made.

Before the form is posted to the server, client side validation checks any validation rules on the fields. If there are any validation errors, an error message is displayed and the form isn't posted. If JavaScript is disabled, you won't have client side validation but the server will detect the posted values that are not valid, and the form values will be redisplayed with error messages. Later in the tutorial we examine [Model Validation](#) in more detail. The [Validation Tag Helper](#) in the `Views/Movies/Edit.cshtml` view template takes care of displaying appropriate error messages.

All the `[HttpGet]` methods in the movie controller follow a similar pattern. They get a movie object (or list of objects, in the case of `Index`), and pass the object (model) to the view. The `Create` method passes an empty movie object to the `Create` view. All the methods that create, edit, delete, or otherwise modify data do so in the `[HttpPost]` overload of the method. Modifying data in an `HTTP GET` method is a security risk. Modifying data in an `HTTP GET` method also violates HTTP best practices and the architectural `REST` pattern, which specifies that GET requests shouldn't change the state of your application. In other words, performing a GET operation should be a safe operation that has no side effects and doesn't modify your persisted data.

[PREVIOUS - WORKING WITH  
SQLITE](#)

[NEXT - ADD  
SEARCH](#)

# Add search to an ASP.NET Core MVC app

6/26/2018 • 7 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section you add search capability to the `Index` action method that lets you search movies by *genre* or *name*.

Update the `Index` method with the following code:

```
public async Task<IActionResult> Index(string searchString)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    return View(await movies.ToListAsync());
}
```

The first line of the `Index` action method creates a [LINQ](#) query to select the movies:

```
var movies = from m in _context.Movie
             select m;
```

The query is *only* defined at this point, it has **not** been run against the database.

If the `searchString` parameter contains a string, the movies query is modified to filter on the value of the search string:

```
if (!String.IsNullOrEmpty(searchString))
{
    movies = movies.Where(s => s.Title.Contains(searchString));
}
```

The `s => s.Title.Contains()` code above is a [Lambda Expression](#). Lambdas are used in method-based [LINQ](#) queries as arguments to standard query operator methods such as the `Where` method or `Contains` (used in the code above). LINQ queries are not executed when they're defined or when they're modified by calling a method such as `Where`, `Contains` or `OrderBy`. Rather, query execution is deferred. That means that the evaluation of an expression is delayed until its realized value is actually iterated over or the `ToListAsync` method is called. For more information about deferred query execution, see [Query Execution](#).

Note: The `Contains` method is run on the database, not in the c# code shown above. The case sensitivity on the query depends on the database and the collation. On SQL Server, `Contains` maps to [SQL LIKE](#), which is case insensitive. In SQLite, with the default collation, it's case sensitive.

Navigate to `/Movies/Index`. Append a query string such as `?searchString=Ghost` to the URL. The filtered movies are displayed.

Title	Release Date	Genre	Price
Ghostbusters	3/13/1984	Comedy	8.99
Ghostbusters 2	2/23/1986	Comedy	9.99

If you change the signature of the `Index` method to have a parameter named `id`, the `id` parameter will match the optional `{id}` placeholder for the default routes set in `Startup.cs`.

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

Note: SQLite is case sensitive, so you'll need to search for "Ghost" and not "ghost".

The previous `Index` method:

```
public async Task<IActionResult> Index(string searchString)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    return View(await movies.ToListAsync());
}
```

The updated `Index` method with `id` parameter:

```
public async Task<IActionResult> Index(string id)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(id))
    {
        movies = movies.Where(s => s.Title.Contains(id));
    }

    return View(await movies.ToListAsync());
}
```

You can now pass the search title as route data (a URL segment) instead of as a query string value.

Mvc Movie

# Index

Create New

Genre	Price	Release Date	Title	
Comedy	8.99	3/13/1984	Ghostbusters	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	9.99	2/23/1986	Ghostbusters 2	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

© 2015 - MvcMovie

However, you can't expect users to modify the URL every time they want to search for a movie. So now you'll add UI elements to help them filter movies. If you changed the signature of the `Index` method to test how to pass the route-bound `ID` parameter, change it back so that it takes a parameter named `searchString`:

```
public async Task<IActionResult> Index(string searchString)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    return View(await movies.ToListAsync());
}
```

Open the `Views/Movies/Index.cshtml` file, and add the `<form>` markup highlighted below:

```
ViewData["Title"] = "Index";
}

<h2>Index</h2>

<p>
    <a asp-action="Create">Create New</a>
</p>

<form asp-controller="Movies" asp-action="Index">
    <p>
        Title: <input type="text" name="SearchString">
        <input type="submit" value="Filter" />
    </p>
</form>

<table class="table">
    <thead>
```

The HTML `<form>` tag uses the [Form Tag Helper](#), so when you submit the form, the filter string is posted to the `Index` action of the movies controller. Save your changes and then test the filter.

Genre	Price	Release Date	Title	
Romantic Comedy	7.99	1/11/1989	When Harry Met Sally	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	8.99	3/13/1984	Ghostbusters	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	9.99	2/23/1986	Ghostbusters 2	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Western	3.99	4/15/1959	Rio Bravo	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

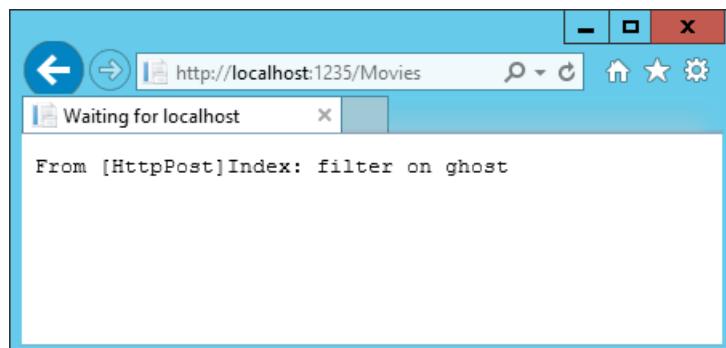

There's no `[HttpPost]` overload of the `Index` method as you might expect. You don't need it, because the method isn't changing the state of the app, just filtering data.

You could add the following `[HttpPost] Index` method.

```
[HttpPost]
public string Index(string searchString, bool notUsed)
{
    return "From [HttpPost]Index: filter on " + searchString;
}
```

The `notUsed` parameter is used to create an overload for the `Index` method. We'll talk about that later in the tutorial.

If you add this method, the action invoker would match the `[HttpPost] Index` method, and the `[HttpPost] Index` method would run as shown in the image below.

However, even if you add this `[HttpPost]` version of the `Index` method, there's a limitation in how this has all been implemented. Imagine that you want to bookmark a particular search or you want to send a link to friends that they can click in order to see the same filtered list of movies. Notice that the URL for the HTTP POST request is the same as the URL for the GET request (`localhost:xxxx/Movies/Index`) -- there's no search information in the

URL. The search string information is sent to the server as a [form field value](#). You can verify that with the browser Developer tools or the excellent [Fiddler tool](#). The image below shows the Chrome browser Developer tools:

The screenshot shows the Chrome Developer Tools Network tab with a red box highlighting the 'Network' tab itself. Below it, another red box highlights the 'Movies' entry in the list of requests. The 'General' section of the request details is also highlighted with a red box, showing the Request URL, Method, Status Code (200 OK), and other headers like Cache-Control, Content-Type, Date, Pragma, Server, and Transfer-Encoding. The 'Form Data' section is also highlighted with a red box, showing the 'SearchString' parameter with the value 'Ghost' and a long 'RequestVerificationToken' parameter.

You can see the search parameter and [XSRF](#) token in the request body. Note, as mentioned in the previous tutorial, the [Form Tag Helper](#) generates an [XSRF](#) anti-forgery token. We're not modifying data, so we don't need to validate the token in the controller method.

Because the search parameter is in the request body and not the URL, you can't capture that search information to bookmark or share with others. We'll fix this by specifying the request should be [HTTP GET](#).

Change the `<form>` tag in the `Views\movie\Index.cshtml` Razor view to specify `method="get"`:

```
<form asp-controller="Movies" asp-action="Index" method="get">
```

Now when you submit a search, the URL contains the search query string. Searching will also go to the `HttpGet Index` action method, even if you have a `HttpPost Index` method.

Genre	Price	Release Date	Title	
Comedy	8.99	3/13/1984	Ghostbusters	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	9.99	2/23/1986	Ghostbusters 2	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

The following markup shows the change to the `form` tag:

```
<form asp-controller="Movies" asp-action="Index" method="get">
```

## Adding Search by genre

Add the following `MovieGenreViewModel` class to the *Models* folder:

```
using Microsoft.AspNetCore.Mvc.Rendering;
using System.Collections.Generic;

namespace MvcMovie.Models
{
    public class MovieGenreViewModel
    {
        public List<Movie> movies;
        public SelectList genres;
        public string movieGenre { get; set; }
    }
}
```

The movie-genre view model will contain:

- A list of movies.
- A `selectList` containing the list of genres. This will allow the user to select a genre from the list.
- `movieGenre`, which contains the selected genre.

Replace the `Index` method in `MoviesController.cs` with the following code:

```

// Requires using Microsoft.AspNetCore.Mvc.Rendering;
public async Task<IActionResult> Index(string movieGenre, string searchString)
{
    // Use LINQ to get list of genres.
    IQueryable<string> genreQuery = from m in _context.Movie
                                         orderby m.Genre
                                         select m.Genre;

    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    if (!String.IsNullOrEmpty(movieGenre))
    {
        movies = movies.Where(x => x.Genre == movieGenre);
    }

    var movieGenreVM = new MovieGenreViewModel();
    movieGenreVM.genres = new SelectList(await genreQuery.Distinct().ToListAsync());
    movieGenreVM.movies = await movies.ToListAsync();

    return View(movieGenreVM);
}

```

The following code is a `LINQ` query that retrieves all the genres from the database.

```

// Use LINQ to get list of genres.
IQueryable<string> genreQuery = from m in _context.Movie
                                         orderby m.Genre
                                         select m.Genre;

```

The `SelectList` of genres is created by projecting the distinct genres (we don't want our select list to have duplicate genres).

```
movieGenreVM.genres = new SelectList(await genreQuery.Distinct().ToListAsync())
```

## Adding search by genre to the Index view

Update `Index.cshtml` as follows:

```

@model MvcMovie.Models.MovieGenreViewModel

 @{
     ViewData["Title"] = "Index";
 }

<h2>Index</h2>

<p>
    <a asp-action="Create">Create New</a>
</p>

<form asp-controller="Movies" asp-action="Index" method="get">
    <p>
        <select asp-for="movieGenre" asp-items="Model.genres">
            <option value="">All</option>
        </select>

        Title: <input type="text" name="SearchString">
        <input type="submit" value="Filter" />
    </p>
</form>

<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Title)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].ReleaseDate)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Genre)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Price)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
        @foreach (var item in Model.movies)
        {
            <tr>
                <td>
                    @Html.DisplayFor(modelItem => item.Title)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.ReleaseDate)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Genre)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Price)
                </td>
                <td>
                    <a asp-action="Edit" asp-route-id="@item.ID">Edit</a> |
                    <a asp-action="Details" asp-route-id="@item.ID">Details</a> |
                    <a asp-action="Delete" asp-route-id="@item.ID">Delete</a>
                </td>
            </tr>
        }
    </tbody>
</table>

```

Examine the lambda expression used in the following HTML Helper:

```
@Html.DisplayNameFor(model => model.movies[0].Title)
```

In the preceding code, the `DisplayNameFor` HTML Helper inspects the `Title` property referenced in the lambda expression to determine the display name. Since the lambda expression is inspected rather than evaluated, you don't receive an access violation when `model`, `model.movies`, or `model.movies[0]` are `null` or empty. When the lambda expression is evaluated (for example, `@Html.DisplayFor(modelItem => item.Title)`), the model's property values are evaluated.

Test the app by searching by genre, by movie title, and by both.

[PREVIOUS - CONTROLLER METHODS AND  
VIEWS](#)

[NEXT - ADD A  
FIELD](#)

# Add a new field to an ASP.NET Core MVC app

6/26/2018 • 3 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

This tutorial will add a new field to the `Movies` table. We'll drop the database and create a new one when we change the schema (add a new field). This workflow works well early in development when we don't have any production data to preserve.

Once your app is deployed and you have data that you need to preserve, you can't drop your DB when you need to change the schema. Entity Framework [Code First Migrations](#) allows you to update your schema and migrate the database without losing data. Migrations is a popular feature when using SQL Server, but SQLite doesn't support many migration schema operations, so only very simple migrations are possible. See [SQLite Limitations](#) for more information.

## Adding a Rating Property to the Movie Model

Open the `Models/Movie.cs` file and add a `Rating` property:

```
public class Movie
{
    public int ID { get; set; }
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }
    public string Genre { get; set; }

    [Column(TypeName = "decimal(18, 2)")]
    public decimal Price { get; set; }
    public string Rating { get; set; }
}
```

```
public class Movie
{
    public int ID { get; set; }
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }
    public string Genre { get; set; }
    public decimal Price { get; set; }
    public string Rating { get; set; }
}
```

Because you've added a new field to the `Movie` class, you also need to update the binding whitelist so this new property will be included. In `MoviesController.cs`, update the `[Bind]` attribute for both the `Create` and `Edit` action methods to include the `Rating` property:

```
[Bind("ID,Title,ReleaseDate,Genre,Price,Rating")]
```

You also need to update the view templates in order to display, create, and edit the new `Rating` property in the browser view.

Edit the `/Views/Movies/Index.cshtml` file and add a `Rating` field:

```
<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Title)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].ReleaseDate)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Genre)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Price)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Rating)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
        @foreach (var item in Model.movies)
        {
            <tr>
                <td>
                    @Html.DisplayFor(modelItem => item.Title)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.ReleaseDate)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Genre)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Price)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Rating)
                </td>
                <td>
```

Update the `/Views/Movies/Create.cshtml` with a `Rating` field.

The app won't work until we update the DB to include the new field. If you run it now, you'll get the following `SqliteException`:

```
SqliteException: SQLite Error 1: 'no such column: m.Rating'.
```

You're seeing this error because the updated Movie model class is different than the schema of the Movie table of the existing database. (There's no `Rating` column in the database table.)

There are a few approaches to resolving the error:

1. Drop the database and have the Entity Framework automatically re-create the database based on the new model class schema. With this approach, you lose existing data in the database — so you can't do this with a production database! Using an initializer to automatically seed a database with test data is often a

productive way to develop an app.

2. Manually modify the schema of the existing database so that it matches the model classes. The advantage of this approach is that you keep your data. You can make this change either manually or by creating a database change script.
3. Use Code First Migrations to update the database schema.

For this tutorial, we'll drop and re-create the database when the schema changes. Run the following command from a terminal to drop the db:

```
dotnet ef database drop
```

Update the `SeedData` class so that it provides a value for the new column. A sample change is shown below, but you'll want to make this change for each `new Movie`.

```
new Movie
{
    Title = "When Harry Met Sally",
    ReleaseDate = DateTime.Parse("1989-1-11"),
    Genre = "Romantic Comedy",
    Rating = "R",
    Price = 7.99M
},
```

Add the `Rating` field to the `Edit`, `Details`, and `Delete` view.

Run the app and verify you can create/edit/display movies with a `Rating` field. templates.

PREVIOUS - ADD  
SEARCH

NEXT - ADD  
VALIDATION

# Add validation to an ASP.NET Core MVC app

6/26/2018 • 10 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section you'll add validation logic to the `Movie` model, and you'll ensure that the validation rules are enforced any time a user creates or edits a movie.

## Keeping things DRY

One of the design tenets of MVC is [DRY](#) ("Don't Repeat Yourself"). ASP.NET MVC encourages you to specify functionality or behavior only once, and then have it be reflected everywhere in an app. This reduces the amount of code you need to write and makes the code you do write less error prone, easier to test, and easier to maintain.

The validation support provided by MVC and Entity Framework Core Code First is a good example of the DRY principle in action. You can declaratively specify validation rules in one place (in the model class) and the rules are enforced everywhere in the app.

## Adding validation rules to the movie model

Open the `Movie.cs` file. DataAnnotations provides a built-in set of validation attributes that you apply declaratively to any class or property. (It also contains formatting attributes like `DataType` that help with formatting and don't provide any validation.)

Update the `Movie` class to take advantage of the built-in `Required`, `StringLength`, `RegularExpression`, and `Range` validation attributes.

```
public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3)]
    [Required]
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [Range(1, 100)]
    [DataType(DataType.Currency)]
    [Column(TypeName = "decimal(18, 2)")]
    public decimal Price { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z''"\s-]*$")]
    [Required]
    [StringLength(30)]
    public string Genre { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z0-9'''\s-]*$")]
    [StringLength(5)]
    [Required]
    public string Rating { get; set; }
}
```

```

public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3)]
    [Required]
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [Range(1, 100)]
    [DataType(DataType.Currency)]
    public decimal Price { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z\s-]*$")]
    [Required]
    [StringLength(30)]
    public string Genre { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z0-9\s-]*$")]
    [StringLength(5)]
    [Required]
    public string Rating { get; set; }
}

```

The validation attributes specify behavior that you want to enforce on the model properties they're applied to. The `Required` and `MinimumLength` attributes indicate that a property must have a value; but nothing prevents a user from entering white space to satisfy this validation. The `RegularExpression` attribute is used to limit what characters can be input. In the code above, `Genre` and `Rating` must use only letters (First letter uppercase, white space, numbers and special characters are not allowed). The `Range` attribute constrains a value to within a specified range. The `StringLength` attribute lets you set the maximum length of a string property, and optionally its minimum length. Value types (such as `decimal`, `int`, `float`, `DateTime`) are inherently required and don't need the `[Required]` attribute.

Having validation rules automatically enforced by ASP.NET helps make your app more robust. It also ensures that you can't forget to validate something and inadvertently let bad data into the database.

## Validation Error UI in MVC

Run the app and navigate to the Movies controller.

Tap the **Create New** link to add a new movie. Fill out the form with some invalid values. As soon as jQuery client side validation detects the error, it displays an error message.

The screenshot shows a browser window titled "Create - Movie App" with the URL "localhost:5000/Movies/Create". The page is titled "Create Movie". It contains a form with the following fields and validation errors:

- Title**: An input field with a red border and error message: "The field Title must be a string with a minimum length of 3 and a maximum length of 60."
- Release Date**: An input field with a red border and error message: "The field Release Date is required."
- Genre**: An input field with a red border and error message: "The field Genre is required."
- Price**: An input field with a red border and error message: "The field Price must be a number."
- Rating**: An input field with a red border and error message: "The field Rating must match the regular expression '^([A-Z]+[a-zA-Z-\s]\*)\$'."

At the bottom of the form are two buttons: "Create" and "Back to List".

#### NOTE

You may not be able to enter decimal commas in the `Price` field. To support [jQuery validation](#) for non-English locales that use a comma (",") for a decimal point, and non US-English date formats, you must take steps to globalize your app. This [GitHub issue 4076](#) for instructions on adding decimal comma.

Notice how the form has automatically rendered an appropriate validation error message in each field containing an invalid value. The errors are enforced both client-side (using JavaScript and jQuery) and server-side (in case a user has JavaScript disabled).

A significant benefit is that you didn't need to change a single line of code in the `MoviesController` class or in the `Create.cshtml` view in order to enable this validation UI. The controller and views you created earlier in this tutorial automatically picked up the validation rules that you specified by using validation attributes on the properties of the `Movie` model class. Test validation using the `Edit` action method, and the same validation is applied.

The form data isn't sent to the server until there are no client side validation errors. You can verify this by putting a break point in the `HTTP Post` method, by using the [Fiddler tool](#), or the [F12 Developer tools](#).

## How validation works

You might wonder how the validation UI was generated without any updates to the code in the controller or views. The following code shows the two `Create` methods.

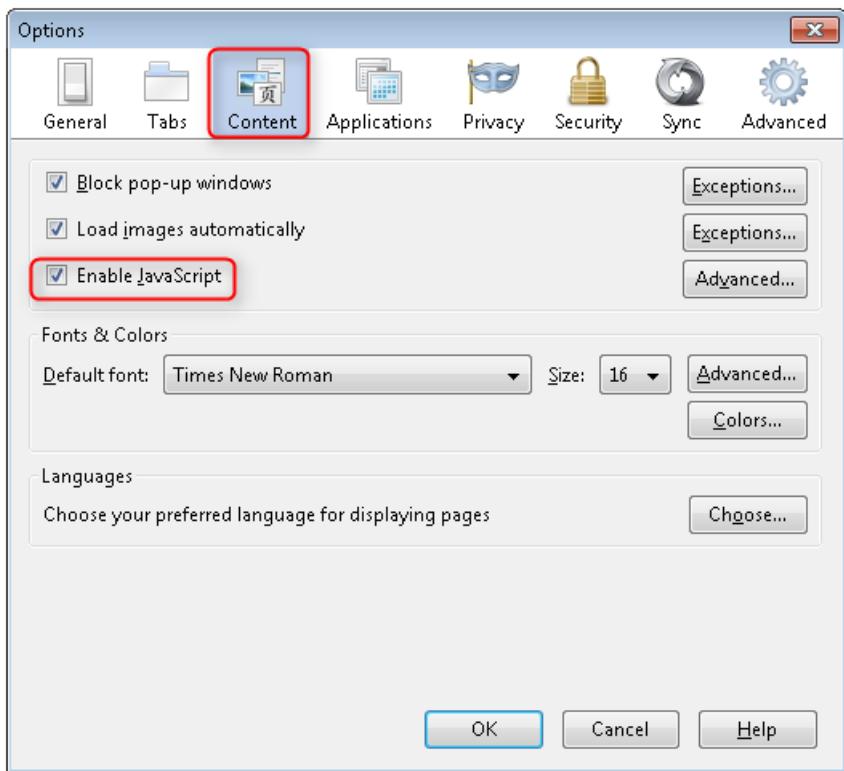

```
// GET: Movies/Create
public IActionResult Create()
{
    return View();
}

// POST: Movies/Create
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Create(
    [Bind("ID,Title,ReleaseDate,Genre,Price, Rating")] Movie movie)
{
    if (ModelState.IsValid)
    {
        _context.Add(movie);
        await _context.SaveChangesAsync();
        return RedirectToAction("Index");
    }
    return View(movie);
}
```

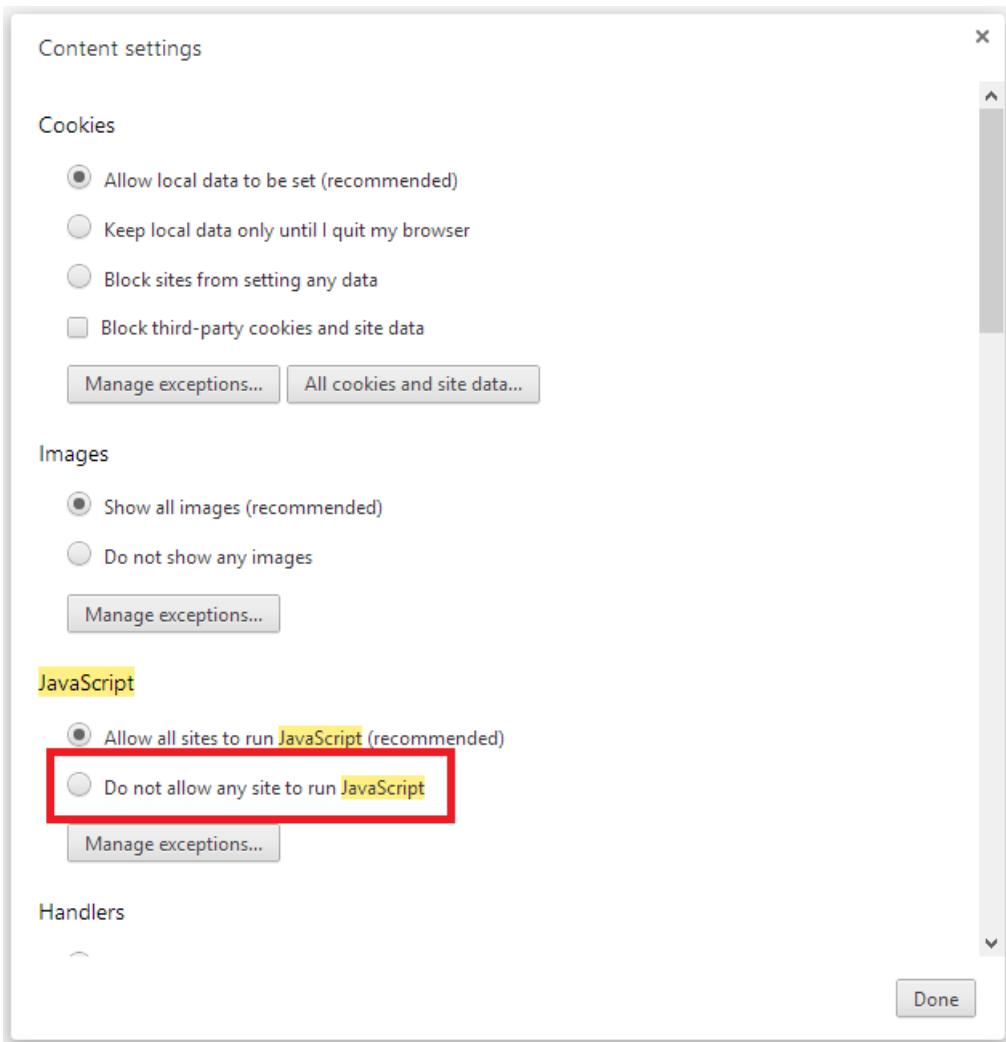

The first (HTTP GET) `Create` action method displays the initial Create form. The second (`[HttpPost]`) version handles the form post. The second `Create` method (The `[HttpPost]` version) calls `ModelState.IsValid` to check whether the movie has any validation errors. Calling this method evaluates any validation attributes that have been applied to the object. If the object has validation errors, the `Create` method re-displays the form. If there are no errors, the method saves the new movie in the database. In our movie example, the form isn't posted to the server when there are validation errors detected on the client side; the second `Create` method is never called when there are client side validation errors. If you disable JavaScript in your browser, client validation is disabled and you can test the HTTP POST `Create` method `ModelState.IsValid` detecting any validation errors.

You can set a break point in the `[HttpPost] Create` method and verify the method is never called, client side validation won't submit the form data when validation errors are detected. If you disable JavaScript in your browser, then submit the form with errors, the break point will be hit. You still get full validation without JavaScript.

The following image shows how to disable JavaScript in the FireFox browser.

The following image shows how to disable JavaScript in the Chrome browser.

After you disable JavaScript, post invalid data and step through the debugger.

```
74     // POST: Movies/Create
75     // To protect from overposting attacks, please enable t
76     // more details see http://go.microsoft.com/fwlink/?LinkID=142072
77     [HttpPost]
78     [ValidateAntiForgeryToken]
79     0 references
80     public async Task<IActionResult> Create([Bind("ID,Title")]
81     {
82         if (ModelState.IsValid)
83         {
84             _context.Add(movie);
85             await _context.SaveChangesAsync();
86             return RedirectToAction("Index");
87         }
88         return View(movie);
89     }

```

Below is portion of the `Create.cshtml` view template that you scaffolded earlier in the tutorial. It's used by the action methods shown above both to display the initial form and to redisplay it in the event of an error.

```
<form asp-action="Create">
    <div class="form-horizontal">
        <h4>Movie</h4>
        <hr />

        <div asp-validation-summary="ModelOnly" class="text-danger"></div>
        <div class="form-group">
            <label asp-for="Title" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Title" class="form-control" />
                <span asp-validation-for="Title" class="text-danger"></span>
            </div>
        </div>

        @*Markup removed for brevity.*@
    </div>
</form>
```

The [Input Tag Helper](#) uses the [DataAnnotations](#) attributes and produces HTML attributes needed for jQuery Validation on the client side. The [Validation Tag Helper](#) displays validation errors. See [Validation](#) for more information.

What's really nice about this approach is that neither the controller nor the `Create` view template knows anything about the actual validation rules being enforced or about the specific error messages displayed. The validation rules and the error strings are specified only in the `Movie` class. These same validation rules are automatically applied to the `Edit` view and any other views templates you might create that edit your model.

When you need to change validation logic, you can do so in exactly one place by adding validation attributes to the model (in this example, the `Movie` class). You won't have to worry about different parts of the application being inconsistent with how the rules are enforced — all validation logic will be defined in one place and used everywhere. This keeps the code very clean, and makes it easy to maintain and evolve. And it means that you'll be fully honoring the DRY principle.

## Using DataType Attributes

Open the `Movie.cs` file and examine the `Movie` class. The `System.ComponentModel.DataAnnotations` namespace provides formatting attributes in addition to the built-in set of validation attributes. We've already applied a `DataType` enumeration value to the release date and to the price fields. The following code shows the `ReleaseDate` and `Price` properties with the appropriate `DataType` attribute.

```
[Display(Name = "Release Date")]
[DataType(DataType.Date)]
public DateTime ReleaseDate { get; set; }

[Range(1, 100)]
[DataType(DataType.Currency)]
public decimal Price { get; set; }
```

The `DataType` attributes only provide hints for the view engine to format the data (and supplies elements/attributes such as `<a>` for URL's and `<a href="mailto:EmailAddress.com">` for email). You can use the `RegularExpression` attribute to validate the format of the data. The `DataType` attribute is used to specify a data type that's more specific than the database intrinsic type, they're not validation attributes. In this case we only want to keep track of the date, not the time. The `DataType` Enumeration provides for many data types, such as Date, Time, PhoneNumber, Currency, EmailAddress and more. The `DataType` attribute can also enable the application to automatically provide type-specific features. For example, a `mailto:` link can be created for `DataType.EmailAddress`, and a date selector can be provided for `DataType.Date` in browsers that support HTML5. The `DataType` attributes emits HTML 5 `data-` (pronounced data dash) attributes that HTML 5 browsers can understand. The `DataType` attributes do **not** provide any validation.

`DataType.Date` doesn't specify the format of the date that's displayed. By default, the data field is displayed according to the default formats based on the server's `CultureInfo`.

The `DisplayFormat` attribute is used to explicitly specify the date format:

```
[DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
public DateTime ReleaseDate { get; set; }
```

The `ApplyFormatInEditMode` setting specifies that the formatting should also be applied when the value is displayed in a text box for editing. (You might not want that for some fields — for example, for currency values, you probably don't want the currency symbol in the text box for editing.)

You can use the `DisplayFormat` attribute by itself, but it's generally a good idea to use the `DataType` attribute. The `DataType` attribute conveys the semantics of the data as opposed to how to render it on a screen, and provides the following benefits that you don't get with `DisplayFormat`:

- The browser can enable HTML5 features (for example to show a calendar control, the locale-appropriate currency symbol, email links, etc.)
- By default, the browser will render data using the correct format based on your locale.
- The `DataType` attribute can enable MVC to choose the right field template to render the data (the `DisplayFormat` if used by itself uses the string template).

#### NOTE

jQuery validation doesn't work with the `Range` attribute and `DateTime`. For example, the following code will always display a client side validation error, even when the date is in the specified range:

```
[Range(typeof(DateTime), "1/1/1966", "1/1/2020")]
```

You will need to disable jQuery date validation to use the `Range` attribute with `DateTime`. It's generally not a good practice to compile hard dates in your models, so using the `Range` attribute and `DateTime` is discouraged.

The following code shows combining attributes on one line:

```

public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3)]
    public string Title { get; set; }

    [Display(Name = "Release Date"), DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [RegularExpression(@"^([A-Z]+[a-zA-Z\s-]*)$"), Required, StringLength(30)]
    public string Genre { get; set; }

    [Range(1, 100), DataType(DataType.Currency)]
    [Column(TypeName = "decimal(18, 2)")]
    public decimal Price { get; set; }

    [RegularExpression(@"^([A-Z]+[a-zA-Z0-9\s-]*)$"), StringLength(5)]
    public string Rating { get; set; }
}

```

```

public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3), Required]
    public string Title { get; set; }

    [Display(Name = "Release Date"), DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [RegularExpression(@"^([A-Z]+[a-zA-Z\s-]*)$"), Required, StringLength(30)]
    public string Genre { get; set; }

    [Range(1, 100), DataType(DataType.Currency)]
    public decimal Price { get; set; }

    [RegularExpression(@"^([A-Z]+[a-zA-Z0-9\s-]*)$"), Required, StringLength(5)]
    public string Rating { get; set; }
}

```

In the next part of the series, we'll review the application and make some improvements to the automatically generated `Details` and `Delete` methods.

METHODS](#)

# Examine the Details and Delete methods of an ASP.NET Core app

6/21/2018 • 3 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

Open the Movie controller and examine the `Details` method:

```
// GET: Movies/Details/5
public async Task<IActionResult> Details(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .FirstOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}
```

```
// GET: Movies/Details/5
public async Task<IActionResult> Details(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .SingleOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}
```

The MVC scaffolding engine that created this action method adds a comment showing an HTTP request that invokes the method. In this case it's a GET request with three URL segments, the `Movies` controller, the `Details` method and an `id` value. Recall these segments are defined in *Startup.cs*.

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

EF makes it easy to search for data using the `SingleOrDefaultAsync` method. An important security feature built into the method is that the code verifies that the search method has found a movie before it tries to do anything with it. For example, a hacker could introduce errors into the site by changing the URL created by the links from `http://localhost:xxxx/Movies/Details/1` to something like `http://localhost:xxxx/Movies/Details/12345` (or some other value that doesn't represent an actual movie). If you didn't check for a null movie, the app would throw an exception.

Examine the `Delete` and `DeleteConfirmed` methods.

```
// GET: Movies/Delete/5
public async Task<IActionResult> Delete(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .FirstOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}

// POST: Movies/Delete/5
[HttpPost, ActionName("Delete")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> DeleteConfirmed(int id)
{
    var movie = await _context.Movie.FindAsync(id);
    _context.Movie.Remove(movie);
    await _context.SaveChangesAsync();
    return RedirectToAction(nameof(Index));
}
```

```

// GET: Movies/Delete/5
public async Task<IActionResult> Delete(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .SingleOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}

// POST: Movies/Delete/5
[HttpPost, ActionName("Delete")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> DeleteConfirmed(int id)
{
    var movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);
    _context.Movie.Remove(movie);
    await _context.SaveChangesAsync();
    return RedirectToAction("Index");
}

```

Note that the `HTTP GET Delete` method doesn't delete the specified movie, it returns a view of the movie where you can submit (`HttpPost`) the deletion. Performing a delete operation in response to a GET request (or for that matter, performing an edit operation, create operation, or any other operation that changes data) opens up a security hole.

The `[HttpPost]` method that deletes the data is named `DeleteConfirmed` to give the HTTP POST method a unique signature or name. The two method signatures are shown below:

```

// GET: Movies/Delete/5
public async Task<IActionResult> Delete(int? id)
{
```

```

// POST: Movies/Delete/5
[HttpPost, ActionName("Delete")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> DeleteConfirmed(int id)
{
```

The common language runtime (CLR) requires overloaded methods to have a unique parameter signature (same method name but different list of parameters). However, here you need two `Delete` methods -- one for GET and one for POST -- that both have the same parameter signature. (They both need to accept a single integer as a parameter.)

There are two approaches to this problem, one is to give the methods different names. That's what the scaffolding mechanism did in the preceding example. However, this introduces a small problem: ASP.NET maps segments of a URL to action methods by name, and if you rename a method, routing normally wouldn't be able to find that method. The solution is what you see in the example, which is to add the `ActionName("Delete")` attribute to the `DeleteConfirmed` method. That attribute performs mapping for the routing system so that a URL that includes `/Delete/` for a POST request will find the `DeleteConfirmed` method.

Another common work around for methods that have identical names and signatures is to artificially change the

signature of the POST method to include an extra (unused) parameter. That's what we did in a previous post when we added the `notUsed` parameter. You could do the same thing here for the `[HttpPost] Delete` method:

```
// POST: Movies/Delete/6
[ValidateAntiForgeryToken]
public async Task<IActionResult> Delete(int id, bool notUsed)
```

## Publish to Azure

See [Publish an ASP.NET Core web app to Azure App Service using Visual Studio](#) for instructions on how to publish this app to Azure using Visual Studio. The app can also be published from the [command line](#).

# Introduction to ASP.NET Core MVC on macOS, Linux, or Windows

6/21/2018 • 2 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

This tutorial will teach you the basics of building an ASP.NET Core MVC web app using [Visual Studio Code \(VS Code\)](#). The tutorial assumes familiarity with VS Code. See [Getting started with VS Code](#) and [Visual Studio Code help](#) for more information.

This tutorial teaches ASP.NET Core MVC web development with controllers and views. Razor Pages is a feature of the ASP.NET Core MVC framework that makes building and testing web UI easier and more productive. You can use Razor pages alongside controllers and views in the same project.

After using Razor pages, many developers prefer it over controllers and views. We recommend you try the [Razor Pages](#) tutorial before the MVC/Controller/Views version. The Razor Pages tutorial:

- Is the preferred approach for new application development.
- Is easier to follow.
- Covers more features.

If you choose this tutorial over the [Razor Pages](#) version, let us know why in [this GitHub issue](#).

There are 3 versions of this tutorial:

- macOS: [Create an ASP.NET Core MVC app with Visual Studio for Mac](#)
- Windows: [Create an ASP.NET Core MVC app with Visual Studio](#)
- macOS, Linux, and Windows: [Create an ASP.NET Core MVC app with Visual Studio Code](#)

## Prerequisites

Install the following:

- [.NET Core SDK 2.0 or later](#)
- [Visual Studio Code](#)
- [C# for Visual Studio Code](#)
- [.NET Core 2.1 SDK or later](#)
- [Visual Studio Code](#)
- [C# for Visual Studio Code](#)

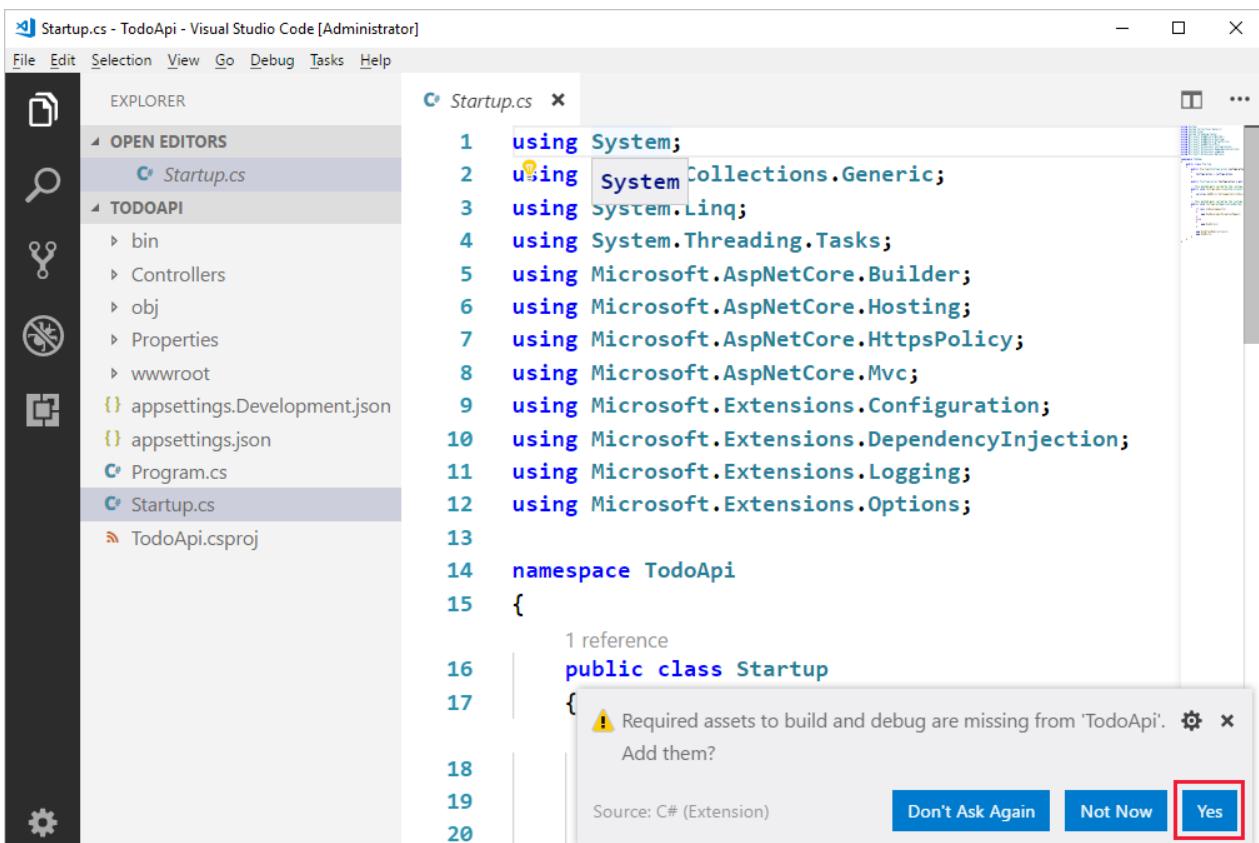

## Create a web app with dotnet

From a terminal, run the following commands:

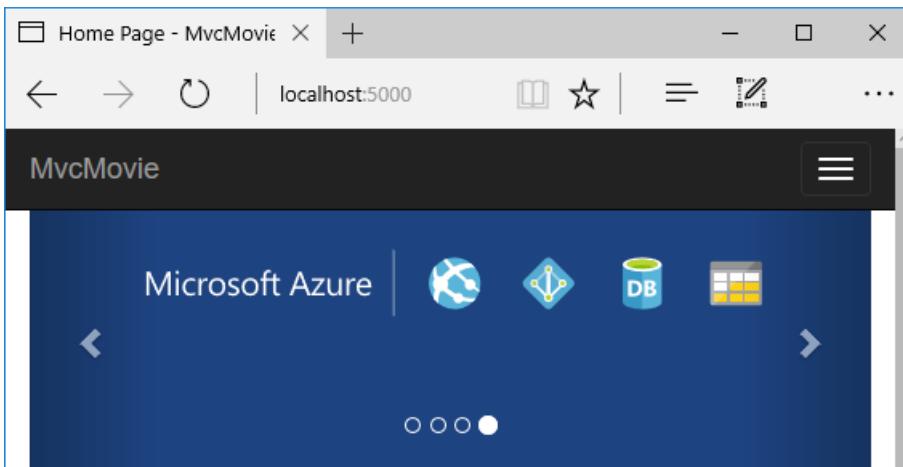

```
mkdir MvcMovie  
cd MvcMovie  
dotnet new mvc
```

Open the *MvcMovie* folder in Visual Studio Code (VS Code) and select the *Startup.cs* file.

- Select **Yes** to the **Warn** message "Required assets to build and debug are missing from 'MvcMovie'. Add them?"
- Select **Restore** to the **Info** message "There are unresolved dependencies".

Press **Debug** (F5) to build and run the program.

## Application uses

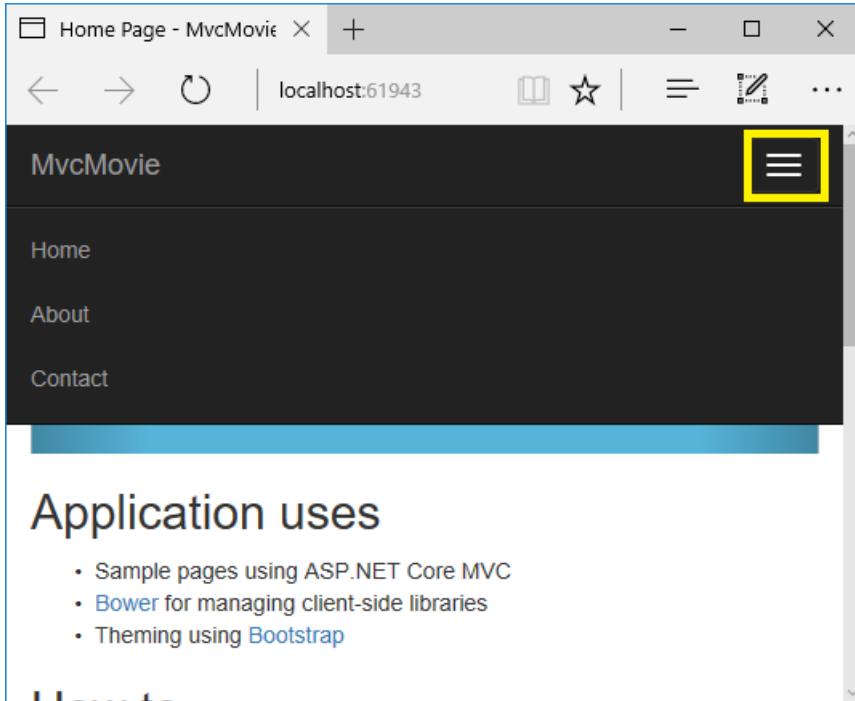

- Sample pages using ASP.NET Core MVC
- Bower for managing client-side libraries
- Theming using Bootstrap

## How to

- Add a Controller and View
- Manage User Secrets using Secret Manager
- Use logging to log a message
- Add packages using NuGet

VS Code starts the **Kestrel** web server and runs your app. Notice that the address bar shows `localhost:5000` and not something like `example.com`. That's because `localhost` is the standard hostname for your local computer.

The default template gives you working **Home**, **About** and **Contact** links. The browser image above doesn't show these links. Depending on the size of your browser, you might need to click the navigation icon to show them.

In the next part of this tutorial, we'll learn about MVC and start writing some code.

[CONTROLLER](#)

# Add a controller to an ASP.NET Core app

6/21/2018 • 5 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

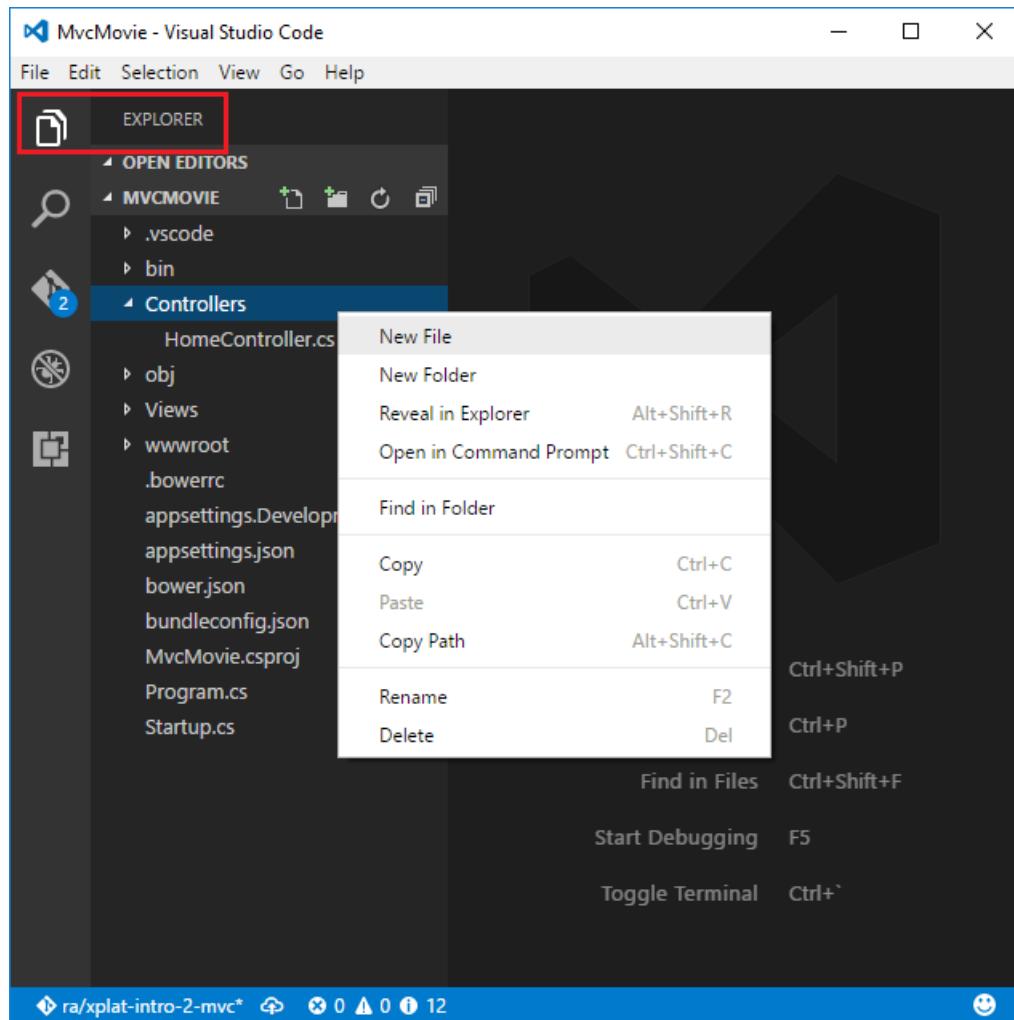

The Model-View-Controller (MVC) architectural pattern separates an app into three main components: **Model**, **View**, and **Controller**. The MVC pattern helps you create apps that are more testable and easier to update than traditional monolithic apps. MVC-based apps contain:

- **Models:** Classes that represent the data of the app. The model classes use validation logic to enforce business rules for that data. Typically, model objects retrieve and store model state in a database. In this tutorial, a `Movie` model retrieves movie data from a database, provides it to the view or updates it. Updated data is written to a database.
- **Views:** Views are the components that display the app's user interface (UI). Generally, this UI displays the model data.
- **Controllers:** Classes that handle browser requests. They retrieve model data and call view templates that return a response. In an MVC app, the view only displays information; the controller handles and responds to user input and interaction. For example, the controller handles route data and query-string values, and passes these values to the model. The model might use these values to query the database. For example,  
`http://localhost:1234/Home/About` has route data of `Home` (the controller) and `About` (the action method to call on the home controller). `http://localhost:1234/Movies/Edit/5` is a request to edit the movie with ID=5 using the movie controller. We'll talk about route data later in the tutorial.

The MVC pattern helps you create apps that separate the different aspects of the app (input logic, business logic, and UI logic), while providing a loose coupling between these elements. The pattern specifies where each kind of logic should be located in the app. The UI logic belongs in the view. Input logic belongs in the controller. Business logic belongs in the model. This separation helps you manage complexity when you build an app, because it enables you to work on one aspect of the implementation at a time without impacting the code of another. For example, you can work on the view code without depending on the business logic code.

We cover these concepts in this tutorial series and show you how to use them to build a movie app. The MVC project contains folders for the *Controllers* and *Views*.

- In **VS Code**, select the **EXPLORER** icon and then control-click (right-click) **Controllers > New File** and name the new file `HelloWorldController.cs`.

Replace the contents of *Controllers/HelloWorldController.cs* with the following:

```
using Microsoft.AspNetCore.Mvc;
using System.Text.Encodings.Web;

namespace MvcMovie.Controllers
{
    public class HelloWorldController : Controller
    {
        //
        // GET: /HelloWorld/

        public string Index()
        {
            return "This is my default action...";
        }

        //
        // GET: /HelloWorld/Welcome/

        public string Welcome()
        {
            return "This is the Welcome action method...";
        }
    }
}
```

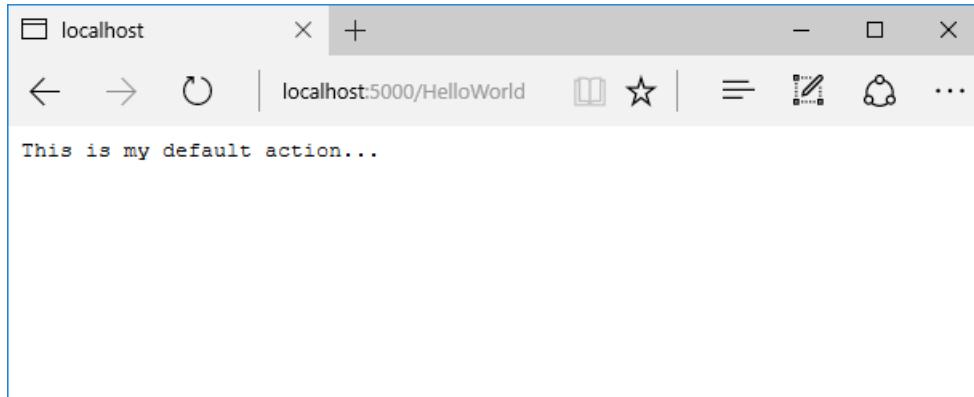

Every `public` method in a controller is callable as an HTTP endpoint. In the sample above, both methods return a string. Note the comments preceding each method.

An HTTP endpoint is a targetable URL in the web application, such as `http://localhost:1234/HelloWorld`, and

combines the protocol used: `HTTP`, the network location of the web server (including the TCP port): `localhost:1234` and the target URI `HelloWorld`.

The first comment states this is an `HTTP GET` method that's invoked by appending `/HelloWorld/` to the base URL. The second comment specifies an `HTTP GET` method that's invoked by appending `/HelloWorld/Welcome/` to the URL. Later on in the tutorial you'll use the scaffolding engine to generate `HTTP POST` methods.

Run the app in non-debug mode and append `"HelloWorld"` to the path in the address bar. The `Index` method returns a string.

MVC invokes controller classes (and the action methods within them) depending on the incoming URL. The [default URL routing logic](#) used by MVC uses a format like this to determine what code to invoke:

```
/[Controller]/[ActionName]/[Parameters]
```

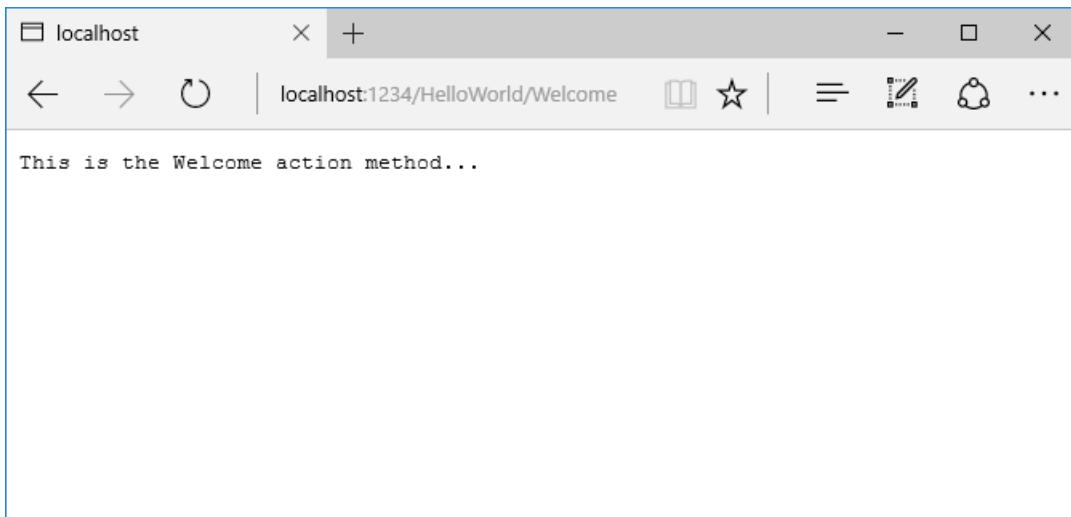

You set the format for routing in the `Configure` method in `Startup.cs` file.

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

When you run the app and don't supply any URL segments, it defaults to the "Home" controller and the "Index" method specified in the template line highlighted above.

The first URL segment determines the controller class to run. So `localhost:xxxx/HelloWorld` maps to the `HelloWorldController` class. The second part of the URL segment determines the action method on the class. So `localhost:xxxx/HelloWorld/Index` would cause the `Index` method of the `HelloWorldController` class to run. Notice that you only had to browse to `localhost:xxxx/HelloWorld` and the `Index` method was called by default. This is because `Index` is the default method that will be called on a controller if a method name isn't explicitly specified. The third part of the URL segment (`id`) is for route data. You'll see route data later on in this tutorial.

Browse to `http://localhost:xxxx/HelloWorld/Welcome`. The `Welcome` method runs and returns the string "This is the Welcome action method...". For this URL, the controller is `HelloWorld` and `Welcome` is the action method. You haven't used the `[Parameters]` part of the URL yet.

Modify the code to pass some parameter information from the URL to the controller. For example, `/HelloWorld/Welcome?name=Rick&numtimes=4`. Change the `Welcome` method to include two parameters as shown in the following code.

```
// GET: /HelloWorld/Welcome/
// Requires using System.Text.Encodings.Web;
public string Welcome(string name, int numTimes = 1)
{
    return HtmlEncoder.Default.Encode($"Hello {name}, NumTimes is: {numTimes}");
}
```

The preceding code:

- Uses the C# optional-parameter feature to indicate that the `numTimes` parameter defaults to 1 if no value is passed for that parameter.
- Uses `HtmlEncoder.Default.Encode` to protect the app from malicious input (namely JavaScript).
- Uses [Interpolated Strings](#).

Run your app and browse to:

```
http://localhost:xxxx>HelloWorld/Welcome?name=Rick&numtimes=4
```

(Replace xxxx with your port number.) You can try different values for `name` and `numtimes` in the URL. The MVC [model binding](#) system automatically maps the named parameters from the query string in the address bar to parameters in your method. See [Model Binding](#) for more information.

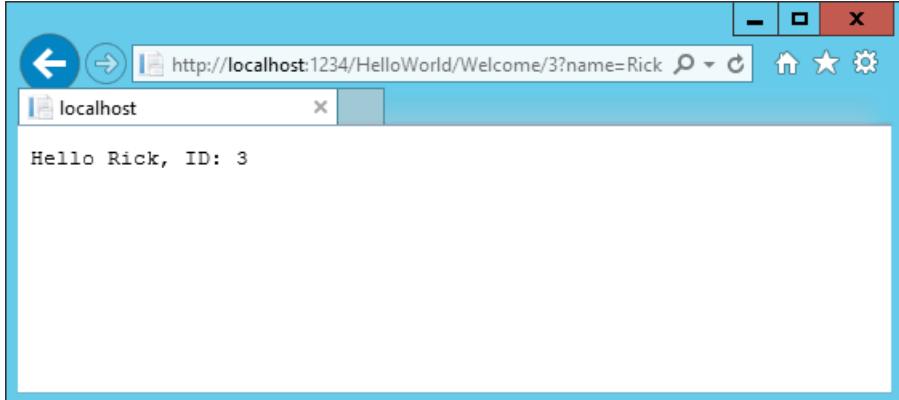

In the image above, the URL segment (`Parameters`) isn't used, the `name` and `numTimes` parameters are passed as [query strings](#). The `?` (question mark) in the above URL is a separator, and the query strings follow. The `&` character separates query strings.

Replace the `Welcome` method with the following code:

```
public string Welcome(string name, int ID = 1)
{
    return HtmlEncoder.Default.Encode($"Hello {name}, ID: {ID}");
}
```

Run the app and enter the following URL: `http://localhost:xxx/HelloWorld/Welcome/3?name=Rick`

This time the third URL segment matched the route parameter `id`. The `Welcome` method contains a parameter `id` that matched the URL template in the `MapRoute` method. The trailing `?` (in `id?`) indicates the `id` parameter is optional.

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

In these examples the controller has been doing the "VC" portion of MVC - that is, the view and controller work. The controller is returning HTML directly. Generally you don't want controllers returning HTML directly, since that becomes very cumbersome to code and maintain. Instead you typically use a separate Razor view template file to help generate the HTML response. You do that in the next tutorial.

[PREVIOUS - ADD A](#)

[CONTROLLER](#)

[NEXT - ADD A](#)

[VIEW](#)

# Add a view to an ASP.NET Core MVC app

6/26/2018 • 8 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section you modify the `HelloWorldController` class to use Razor view template files to cleanly encapsulate the process of generating HTML responses to a client.

You create a view template file using Razor. Razor-based view templates have a `.cshtml` file extension. They provide an elegant way to create HTML output using C#.

Currently the `Index` method returns a string with a message that's hard-coded in the controller class. In the `HelloWorldController` class, replace the `Index` method with the following code:

```
public IActionResult Index()
{
    return View();
}
```

The preceding code returns a `View` object. It uses a view template to generate an HTML response to the browser. Controller methods (also known as action methods) such as the `Index` method above, generally return an `IActionResult` (or a class derived from `ActionResult`), not a type like `string`.

Add an `Index` view for the `HelloWorldController`.

- Add a new folder named `Views/HelloWorld`.
- Add a new file to the `Views/HelloWorld` folder name `Index.cshtml`.

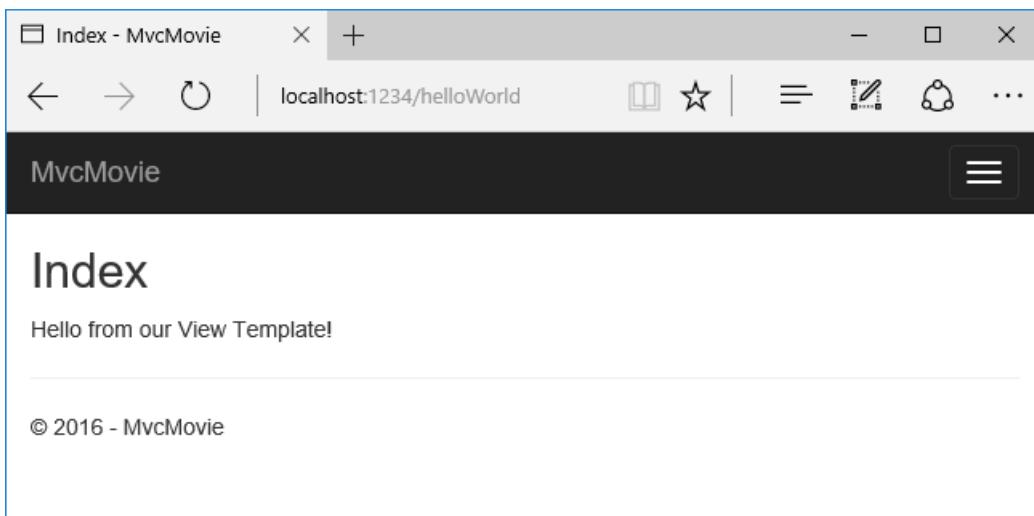

Replace the contents of the `Views/HelloWorld/Index.cshtml` Razor view file with the following:

```
@{
    ViewData["Title"] = "Index";
}

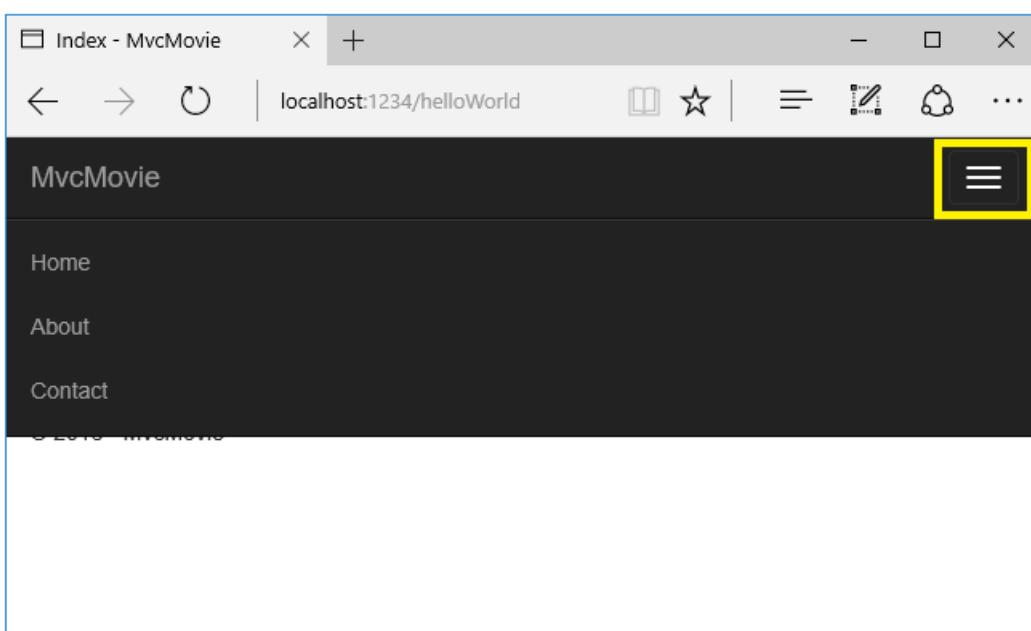

<h2>Index</h2>

<p>Hello from our View Template!</p>
```

Navigate to `http://localhost:xxxx>HelloWorld`. The `Index` method in the `HelloWorldController` didn't do much; it ran the statement `return View();`, which specified that the method should use a view template file to render a response to the browser. Because you didn't explicitly specify the name of the view template file, MVC defaulted to using the `Index.cshtml` view file in the `/Views/HelloWorld` folder. The image below shows the string "Hello from our View Template!" hard-coded in the view.

If your browser window is small (for example on a mobile device), you might need to toggle (tap) the [Bootstrap navigation button](#) in the upper right to see the **Home**, **About**, and **Contact** links.

## Changing views and layout pages

Tap the menu links (**MvcMovie**, **Home**, **About**). Each page shows the same menu layout. The menu layout is implemented in the *Views/Shared/\_Layout.cshtml* file. Open the *Views/Shared/\_Layout.cshtml* file.

[Layout](#) templates allow you to specify the HTML container layout of your site in one place and then apply it across multiple pages in your site. Find the `@RenderBody()` line. `RenderBody` is a placeholder where all the view-specific pages you create show up, *wrapped* in the layout page. For example, if you select the **About** link, the **Views/Home/About.cshtml** view is rendered inside the `RenderBody` method.

## Change the title and menu link in the layout file

In the title element, change `MvcMovie` to `Movie App`. Change the anchor text in the layout template from `MvcMovie` to `Movie App` and the controller from `Home` to `Movies` as highlighted below:

```
@inject Microsoft.ApplicationInsights.AspNetCore.JavaScriptSnippet JavaScriptSnippet
<!DOCTYPE html>
<html>
<head>
    <meta charset="utf-8" />
    <meta name="viewport" content="width=device-width, initial-scale=1.0" />
```

```

<meta name="viewport" content="width=device-width, initial-scale=1.0" />
<title>@ ViewData["Title"] - Movie App</title>

### WARNING

We haven't implemented the `Movies` controller yet, so if you click on that link, you'll get a 404 (Not found) error.

Save your changes and tap the **About** link. Notice how the title on the browser tab now displays **About - Movie App** instead of **About - Mvc Movie**:

Tap the **Contact** link and notice that the title and anchor text also display **Movie App**. We were able to make the change once in the layout template and have all pages on the site reflect the new link text and new title.

Examine the `Views/_ViewStart.cshtml` file:

```

@{
    Layout = "_Layout";
}

```

The `Views/_ViewStart.cshtml` file brings in the `Views/Shared/_Layout.cshtml` file to each view. You can use the `Layout` property to set a different layout view, or set it to `null` so no layout file will be used.

Change the title of the `Index` view.

Open `Views/HelloWorld/Index.cshtml`. There are two places to make a change:

- The text that appears in the title of the browser.
- The secondary header (`<h2>` element).

You'll make them slightly different so you can see which bit of code changes which part of the app.

```
@{
    ViewData["Title"] = "Movie List";
}

<h2>My Movie List</h2>

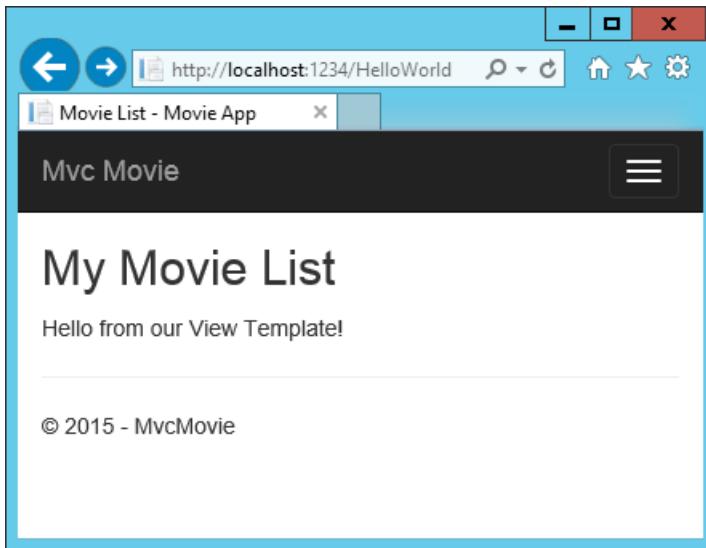

<p>Hello from our View Template!</p>
```

`ViewData["Title"] = "Movie List";` in the code above sets the `Title` property of the `ViewData` dictionary to "Movie List". The `Title` property is used in the `<title>` HTML element in the layout page:

```
<title>@ViewData["Title"] - Movie App</title>
```

Save your change and navigate to `http://localhost:xxxx/HelloWorld`. Notice that the browser title, the primary heading, and the secondary headings have changed. (If you don't see changes in the browser, you might be viewing cached content. Press `Ctrl+F5` in your browser to force the response from the server to be loaded.) The browser title is created with `ViewData["Title"]` we set in the `Index.cshtml` view template and the additional "- Movie App" added in the layout file.

Also notice how the content in the `Index.cshtml` view template was merged with the `Views/Shared/_Layout.cshtml` view template and a single HTML response was sent to the browser. Layout templates make it really easy to make changes that apply across all of the pages in your application. To learn more see [Layout](#).

Our little bit of "data" (in this case the "Hello from our View Template!" message) is hard-coded, though. The MVC application has a "V" (view) and you've got a "C" (controller), but no "M" (model) yet.

## Passing Data from the Controller to the View

Controller actions are invoked in response to an incoming URL request. A controller class is where you write the code that handles the incoming browser requests. The controller retrieves data from a data source and decides what type of response to send back to the browser. View templates can be used from a controller to generate and format an HTML response to the browser.

Controllers are responsible for providing the data required in order for a view template to render a response. A

best practice: View templates should **not** perform business logic or interact with a database directly. Rather, a view template should work only with the data that's provided to it by the controller. Maintaining this "separation of concerns" helps keep your code clean, testable, and maintainable.

Currently, the `Welcome` method in the `HelloWorldController` class takes a `name` and a `ID` parameter and then outputs the values directly to the browser. Rather than have the controller render this response as a string, change the controller to use a view template instead. The view template generates a dynamic response, which means that appropriate bits of data must be passed from the controller to the view in order to generate the response. Do this by having the controller put the dynamic data (parameters) that the view template needs in a `ViewData` dictionary that the view template can then access.

Return to the `HelloWorldController.cs` file and change the `Welcome` method to add a `Message` and `NumTimes` value to the `ViewData` dictionary. The `ViewData` dictionary is a dynamic object, which means you can put whatever you want in to it; the `ViewData` object has no defined properties until you put something inside it. The [MVC model binding system](#) automatically maps the named parameters (`name` and `numTimes`) from the query string in the address bar to parameters in your method. The complete `HelloWorldController.cs` file looks like this:

```
using Microsoft.AspNetCore.Mvc;
using System.Text.Encodings.Web;

namespace MvcMovie.Controllers
{
    public class HelloWorldController : Controller
    {
        public IActionResult Index()
        {
            return View();
        }

        public IActionResult Welcome(string name, int numTimes = 1)
        {
            ViewData["Message"] = "Hello " + name;
            ViewData["NumTimes"] = numTimes;

            return View();
        }
    }
}
```

The `ViewData` dictionary object contains data that will be passed to the view.

Create a `Welcome` view template named `Views/HelloWorld/Welcome.cshtml`.

You'll create a loop in the `Welcome.cshtml` view template that displays "Hello" `NumTimes`. Replace the contents of `Views/HelloWorld/Welcome.cshtml` with the following:

```
@{
    ViewData["Title"] = "Welcome";
}

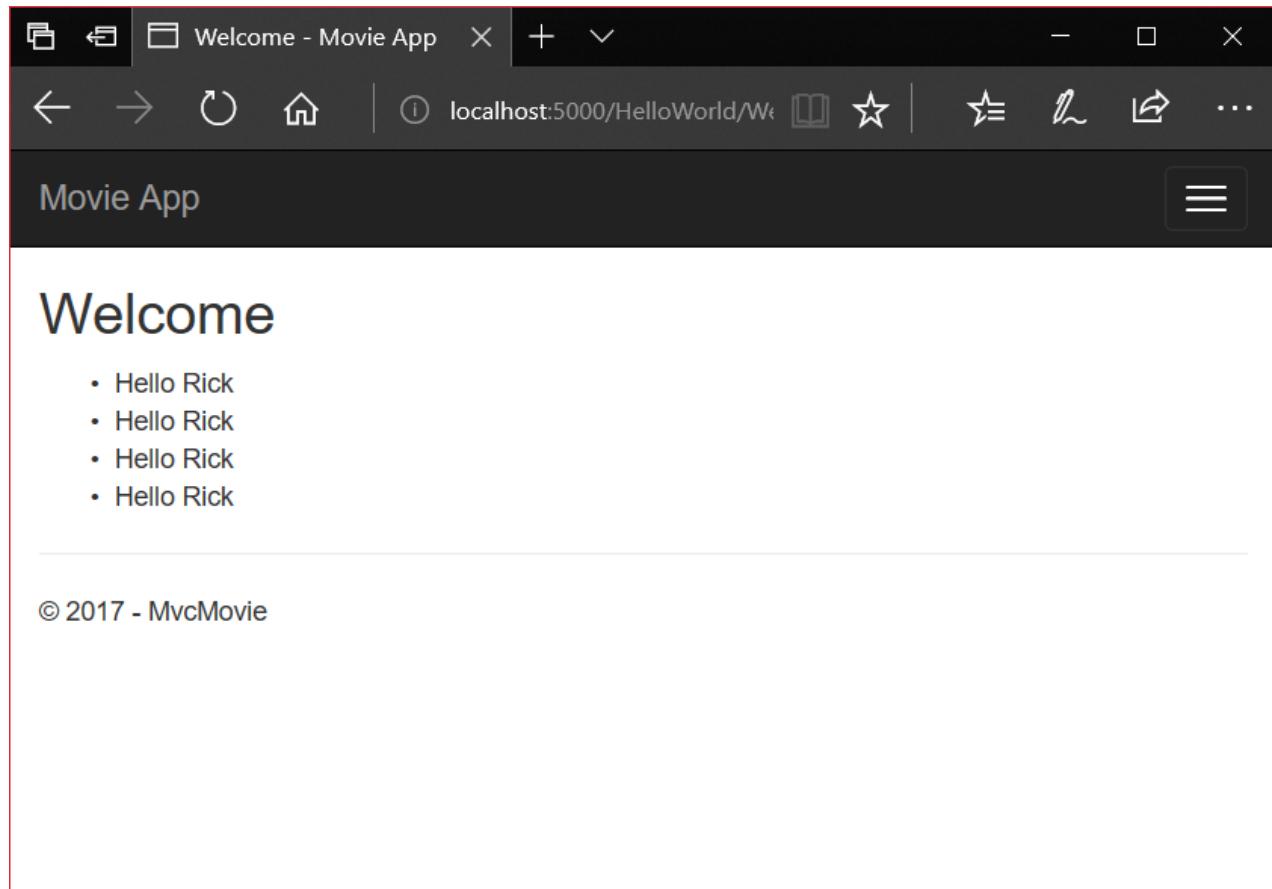

<h2>Welcome</h2>

<ul>
    @for (int i = 0; i < (int)ViewData["NumTimes"]; i++)
    {
        <li>@ViewData["Message"]</li>
    }
</ul>
```

Save your changes and browse to the following URL:

<http://localhost:xxxx/HelloWorld/Welcome?name=Rick&numtimes=4>

Data is taken from the URL and passed to the controller using the [MVC model binder](#). The controller packages the data into a `viewData` dictionary and passes that object to the view. The view then renders the data as HTML to the browser.

In the sample above, we used the `ViewData` dictionary to pass data from the controller to a view. Later in the tutorial, we will use a view model to pass data from a controller to a view. The view model approach to passing data is generally much preferred over the `ViewData` dictionary approach. See [ViewModel vs ViewData vs ViewBag vs TempData vs Session in MVC](#) for more information.

Well, that was a kind of an "M" for model, but not the database kind. Let's take what we've learned and create a database of movies.

[PREVIOUS - ADD A  
CONTROLLER](#)

[NEXT - ADD A  
MODEL](#)

# Add a model to an ASP.NET Core MVC app

6/26/2018 • 4 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Tom Dykstra](#)

In this section, you'll add some classes for managing movies in a database. These classes will be the "Model" part of the **MVC** app.

You use these classes with [Entity Framework Core](#) (EF Core) to work with a database. EF Core is an object-relational mapping (ORM) framework that simplifies the data access code that you have to write. [EF Core supports many database engines](#).

The model classes you'll create are known as POCO classes (from "plain-old CLR objects") because they don't have any dependency on EF Core. They just define the properties of the data that will be stored in the database.

In this tutorial you'll write the model classes first, and EF Core will create the database. An alternate approach not covered here is to generate model classes from an already-existing database. For information about that approach, see [ASP.NET Core - Existing Database](#).

## Add a data model class

- Add a class to the *Models* folder named *Movie.cs*.
- Add the following code to the *Models/Movie.cs* file:

```
using System;

namespace MvcMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

The `ID` field is required by the database for the primary key.

Build the app to verify you don't have any errors, and you've finally added a **Model** to your **MVC** app.

## Prepare the project for scaffolding

- Add the following highlighted NuGet packages to the *MvcMovie.csproj* file:

```

<Project Sdk="Microsoft.NET.Sdk.Web">
  <PropertyGroup>
    <TargetFramework>netcoreapp2.0</TargetFramework>
  </PropertyGroup>
  <ItemGroup>
    <PackageReference Include="Microsoft.AspNetCore.All" Version="2.0.0" />
    <PackageReference Include="Microsoft.VisualStudio.Web.CodeGeneration.Design" Version="2.0.0" />
  </ItemGroup>
  <ItemGroup>
    <DotNetCliToolReference Include="Microsoft.EntityFrameworkCore.Tools.DotNet" Version="2.0.0" />
    <DotNetCliToolReference Include="Microsoft.VisualStudio.Web.CodeGeneration.Tools" Version="2.0.0" />
  </ItemGroup>
</Project>

```

- Save the file and select **Restore** to the **Info** message "There are unresolved dependencies".
- Create a *Models/MvcMovieContext.cs* file and add the following `MvcMovieContext` class:

```

using Microsoft.EntityFrameworkCore;

namespace MvcMovie.Models
{
    public class MvcMovieContext : DbContext
    {
        public MvcMovieContext (DbContextOptions<MvcMovieContext> options)
            : base(options)
        {
        }

        public DbSet<MvcMovie.Models.Movie> Movie { get; set; }
    }
}

```

- Open the *Startup.cs* file and add two usings:

```

using Microsoft.EntityFrameworkCore;
using MvcMovie.Models;

namespace MvcMovie
{
    public class Startup
    {

```

- Add the database context to the *Startup.cs* file:

```

        public void ConfigureServices(IServiceCollection services)
        {
            // Add framework services.
            services.AddMvc();

            services.AddDbContext<MvcMovieContext>(options =>
                options.UseSqlite("Data Source=MvcMovie.db"));
        }

```

This tells Entity Framework which model classes are included in the data model. You're defining one *entity set* of Movie objects, which will be represented in the database as a Movie table.

- Build the project to verify there are no errors.

## Scaffold the MovieController

Open a terminal window in the project folder and run the following commands:

```
dotnet restore  
dotnet aspnet-codegenerator controller -name MoviesController -m Movie -dc MvcMovieContext --  
relativeFolderPath Controllers --useDefaultLayout --referenceScriptLibraries
```

The scaffolding engine creates the following:

- A movies controller (*Controllers/MoviesController.cs*)
- Razor view files for Create, Delete, Details, Edit and Index pages (*Views/Movies/\*.cshtml*)

The automatic creation of **CRUD** (create, read, update, and delete) action methods and views is known as *scaffolding*. You'll soon have a fully functional web application that lets you manage a movie database.

## Perform initial migration

From the command line, run the following .NET Core CLI commands:

```
dotnet ef migrations add InitialCreate  
dotnet ef database update
```

The `dotnet ef migrations add InitialCreate` command generates code to create the initial database schema. The schema is based on the model specified in the `DbContext` (In the *Models/MvcMovieContext.cs* file). The `Initial` argument is used to name the migrations. You can use any name, but by convention you choose a name that describes the migration. See [Introduction to migrations](#) for more information.

The `dotnet ef database update` command runs the `Up` method in the *Migrations/<time-stamp>\_InitialCreate.cs* file, which creates the database.

## Test the app

- Run the app and tap the **Mvc Movie** link.
- Tap the **Create New** link and create a movie.

The screenshot shows a browser window titled "Create - Movie App" with the URL "localhost:1234/Movies/". The page is titled "MvcMovie" and has a header "Create". The form is for creating a "Movie" with fields: "Title" (Conan), "Release Date" (3/3/2017), "Genre" (Comedy), and "Price" (1.99). A "Create" button is at the bottom.

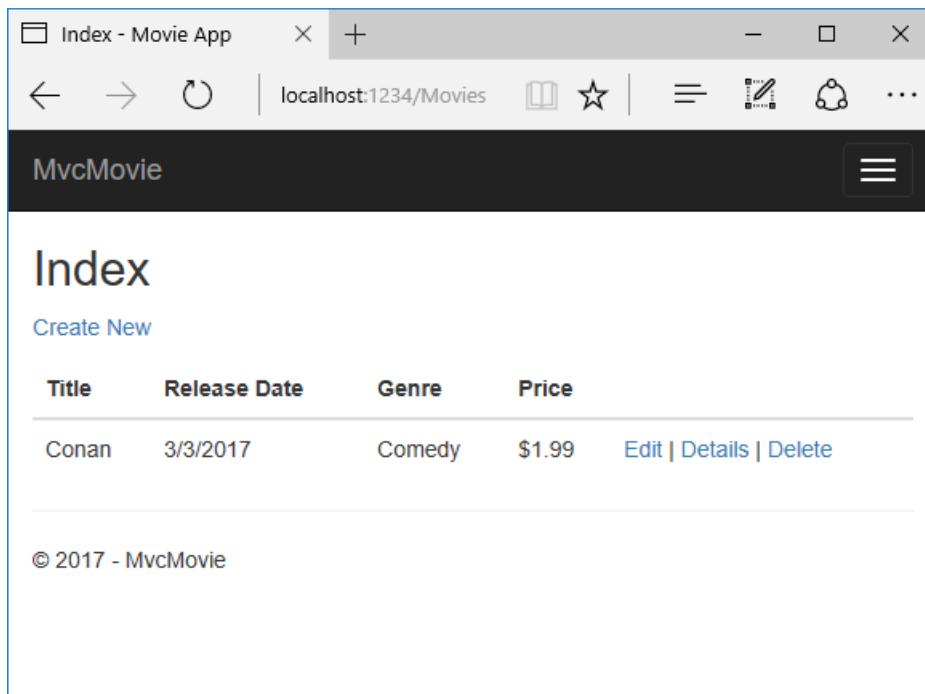

- You may not be able to enter decimal points or commas in the `Price` field. To support [jQuery validation](#) for non-English locales that use a comma (",") for a decimal point, and non US-English date formats, you must take steps to globalize your app. See <https://github.com/aspnet/Docs/issues/4076> and [Additional resources](#) for more information. For now, just enter whole numbers like 10.
- In some locales you need to specify the date format. See the highlighted code below.

```
using System;
using System.ComponentModel.DataAnnotations;

namespace MvcMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }
        [DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

We'll talk about `DataAnnotations` later in the tutorial.

Tapping **Create** causes the form to be posted to the server, where the movie information is saved in a database. The app redirects to the /Movies URL, where the newly created movie information is displayed.

The screenshot shows a mobile browser window titled "Index - Movie App". The address bar indicates the URL is "localhost:1234/Movies". The main content area is titled "MvcMovie" and contains the word "Index". Below this, there is a link "Create New". A table lists a single movie entry:

Title	Release Date	Genre	Price	Action
Conan	3/3/2017	Comedy	\$1.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

At the bottom of the page, there is a copyright notice: "© 2017 - MvcMovie".

Create a couple more movie entries. Try the **Edit**, **Details**, and **Delete** links, which are all functional.

You now have a database and pages to display, edit, update and delete data. In the next tutorial, we'll work with the database.

SQLITE](#)

# Work with SQLite in an ASP.NET Core MVC app

6/26/2018 • 2 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

The `MvcMovieContext` object handles the task of connecting to the database and mapping `Movie` objects to database records. The database context is registered with the [Dependency Injection](#) container in the `ConfigureServices` method in the `Startup.cs` file:

```
public void ConfigureServices(IServiceCollection services)
{
    // Add framework services.
    services.AddMvc();

    services.AddDbContext<MvcMovieContext>(options =>
        options.UseSqlite("Data Source=MvcMovie.db"));

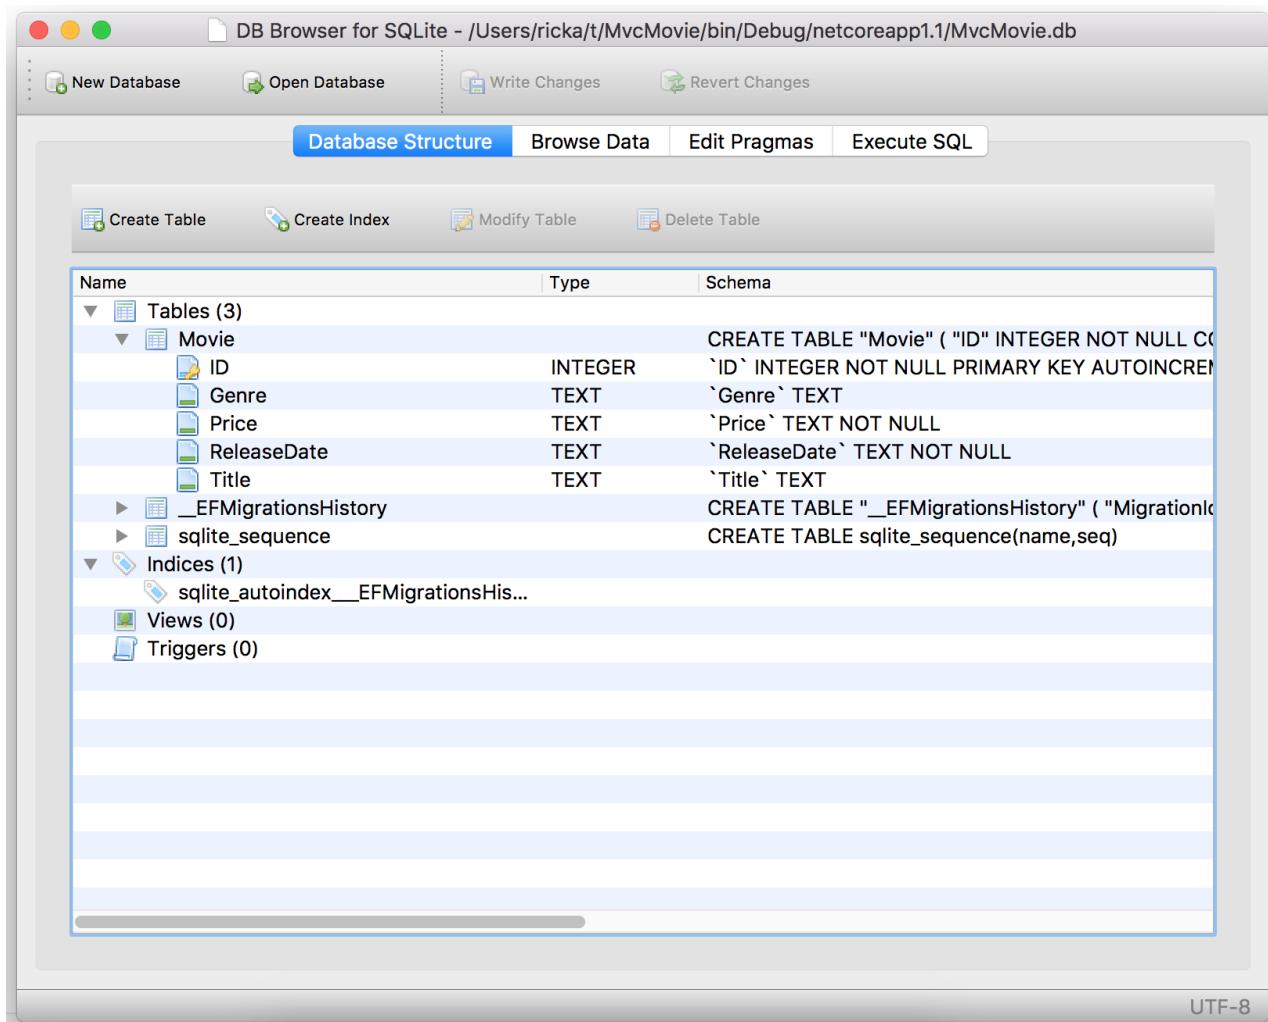

}
```

## SQLite

The [SQLite](#) website states:

SQLite is a self-contained, high-reliability, embedded, full-featured, public-domain, SQL database engine. SQLite is the most used database engine in the world.

There are many third party tools you can download to manage and view a SQLite database. The image below is from [DB Browser for SQLite](#). If you have a favorite SQLite tool, leave a comment on what you like about it.

## Seed the database

Create a new class named `SeedData` in the *Models* folder. Replace the generated code with the following:

```

using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using System;
using System.Linq;

namespace MvcMovie.Models
{
    public static class SeedData
    {
        public static void Initialize(IServiceProvider serviceProvider)
        {
            using (var context = new MvcMovieContext(
                serviceProvider.GetRequiredService<DbContextOptions<MvcMovieContext>>()))
            {
                // Look for any movies.
                if (context.Movie.Any())
                {
                    return; // DB has been seeded
                }

                context.Movie.AddRange(
                    new Movie
                    {
                        Title = "When Harry Met Sally",
                        ReleaseDate = DateTime.Parse("1989-1-11"),
                        Genre = "Romantic Comedy",
                        Price = 7.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters ",
                        ReleaseDate = DateTime.Parse("1984-3-13"),
                        Genre = "Comedy",
                        Price = 8.99M
                    },
                    new Movie
                    {
                        Title = "Ghostbusters 2",
                        ReleaseDate = DateTime.Parse("1986-2-23"),
                        Genre = "Comedy",
                        Price = 9.99M
                    },
                    new Movie
                    {
                        Title = "Rio Bravo",
                        ReleaseDate = DateTime.Parse("1959-4-15"),
                        Genre = "Western",
                        Price = 3.99M
                    }
                );
                context.SaveChanges();
            }
        }
    }
}

```

If there are any movies in the DB, the seed initializer returns.

```
if (context.Movie.Any())
{
    return; // DB has been seeded.
}
```

## Add the seed initializer

Add the seed initializer to the `Main` method in the `Program.cs` file:

```
using Microsoft.AspNetCore;
using Microsoft.AspNetCore.Hosting;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Logging;
using System;
using Microsoft.EntityFrameworkCore;
using MvcMovie.Models;
using MvcMovie;

namespace MvcMovie
{
    public class Program
    {
        public static void Main(string[] args)
        {
            var host = CreateWebHostBuilder(args).Build();

            using (var scope = host.Services.CreateScope())
            {
                var services = scope.ServiceProvider;

                try
                {
                    var context = services.GetRequiredService<MvcMovieContext>();
                    context.Database.Migrate();
                    SeedData.Initialize(services);
                }
                catch (Exception ex)
                {
                    var logger = services.GetRequiredService<ILogger<Program>>();
                    logger.LogError(ex, "An error occurred seeding the DB.");
                }
            }

            host.Run();
        }

        public static IWebHostBuilder CreateWebHostBuilder(string[] args) =>
            WebHost.CreateDefaultBuilder(args)
                .UseStartup<Startup>();
    }
}
```

```

using Microsoft.AspNetCore;
using Microsoft.AspNetCore.Hosting;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Logging;
using MvcMovie.Models;
using System;

namespace MvcMovie
{
    public class Program
    {
        public static void Main(string[] args)
        {
            var host = BuildWebHost(args);

            using (var scope = host.Services.CreateScope())
            {
                var services = scope.ServiceProvider;

                try
                {
                    // Requires using MvcMovie.Models;
                    SeedData.Initialize(services);
                }
                catch (Exception ex)
                {
                    var logger = services.GetRequiredService<ILogger<Program>>();
                    logger.LogError(ex, "An error occurred seeding the DB.");
                }
            }

            host.Run();
        }

        public static IWebHost BuildWebHost(string[] args) =>
            WebHost.CreateDefaultBuilder(args)
                .UseStartup<Startup>()
                .Build();
    }
}

```

## Test the app

Delete all the records in the DB (So the seed method will run). Stop and start the app to seed the database.

The app shows the seeded data.

A screenshot of a Microsoft Edge browser window. The title bar says "Ricka - Movie App". The address bar shows "localhost:5000/Movies". The main content area is titled "MvcMovie" with a "Create New" link. Below is a table listing four movies:

Title	ReleaseDate	Genre	Price	
When Harry Met Sally	1/11/1989 12:00:00 AM	Romantic Comedy	7.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Ghostbusters	3/13/1984 12:00:00 AM	Comedy	8.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Ghostbusters 2	2/23/1986 12:00:00 AM	Comedy	9.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Rio Bravo	4/15/1959 12:00:00 AM	Western	3.99	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

At the bottom left, it says "© 2017 - MvcMovie".

MODEL

NEXT - CONTROLLER METHODS AND  
VIEWS

# Controller methods and views in ASP.NET Core

6/21/2018 • 10 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

We have a good start to the movie app, but the presentation isn't ideal. We don't want to see the time (12:00:00 AM in the image below) and **ReleaseDate** should be two words.

Title	ReleaseDate	Genre	Price
When Harry Met Sally	1/11/1989 12:00:00 AM	Romantic Comedy	7.99
Ghostbusters	3/13/1984 12:00:00 AM	Comedy	8.99
Ghostbusters 2	2/23/1986 12:00:00 AM	Comedy	9.99
Rio Bravo	4/15/1959 12:00:00 AM	Western	3.99

© 2017 - MvcMovie

Open the *Models/Movie.cs* file and add the highlighted lines shown below:

```
using System;
using System.ComponentModel.DataAnnotations;

namespace MvcMovie.Models
{
    public class Movie
    {
        public int ID { get; set; }
        public string Title { get; set; }

        [Display(Name = "Release Date")]
        [DataType(DataType.Date)]
        public DateTime ReleaseDate { get; set; }
        public string Genre { get; set; }
        public decimal Price { get; set; }
    }
}
```

Build and run the app.

We cover [DataAnnotations](#) in the next tutorial. The [Display](#) attribute specifies what to display for the name of a

field (in this case "Release Date" instead of "ReleaseDate"). The `DataType` attribute specifies the type of the data (Date), so the time information stored in the field isn't displayed.

The `[Column(TypeName = "decimal(18, 2)")]` data annotation is required so Entity Framework Core can correctly map `Price` to currency in the database. For more information, see [Data Types](#).

Browse to the `Movies` controller and hold the mouse pointer over an **Edit** link to see the target URL.

Genre	Price	Release Date	Title	
Romantic Comedy	7.99	1/11/1989	When Harry Met Sally	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	8.99	3/13/1984	Ghostbusters	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	9.99	2/23/1986	Ghostbusters 2	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Western	3.99	4/15/1959	Rio Bravo	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

© 2016 - MvcMovie

<http://localhost:1234/Movies/Edit/5>

The **Edit**, **Details**, and **Delete** links are generated by the Core MVC Anchor Tag Helper in the `Views/Movies/Index.cshtml` file.

```
<a asp-action="Edit" asp-route-id="@item.ID">Edit</a> |
<a asp-action="Details" asp-route-id="@item.ID">Details</a> |
<a asp-action="Delete" asp-route-id="@item.ID">Delete</a>
</td>
</tr>
```

[Tag Helpers](#) enable server-side code to participate in creating and rendering HTML elements in Razor files. In the code above, the `AnchorTagHelper` dynamically generates the HTML `href` attribute value from the controller action method and route id. You use **View Source** from your favorite browser or use the developer tools to examine the generated markup. A portion of the generated HTML is shown below:

```
<td>
<a href="/Movies/Edit/4"> Edit </a> |
<a href="/Movies/Details/4"> Details </a> |
<a href="/Movies/Delete/4"> Delete </a>
</td>
```

Recall the format for [routing](#) set in the `Startup.cs` file:

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

ASP.NET Core translates `http://localhost:1234/Movies/Edit/4` into a request to the `Edit` action method of the `Movies` controller with the parameter `Id` of 4. (Controller methods are also known as action methods.)

[Tag Helpers](#) are one of the most popular new features in ASP.NET Core. See [Additional resources](#) for more information.

Open the `Movies` controller and examine the two `Edit` action methods. The following code shows the `HTTP GET Edit` method, which fetches the movie and populates the edit form generated by the `Edit.cshtml` Razor file.

```
// GET: Movies/Edit/5
public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie.FindAsync(id);
    if (movie == null)
    {
        return NotFound();
    }
    return View(movie);
}
```

The following code shows the `HTTP POST Edit` method, which processes the posted movie values:

```

// POST: Movies/Edit/5
// To protect from overposting attacks, please enable the specific properties you want to bind to, for
// more details see http://go.microsoft.com/fwlink/?LinkId=317598.
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction("Index");
    }
    return View(movie);
}

```

```

// GET: Movies/Edit/5
public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }
    return View(movie);
}

```

The following code shows the `HTTP POST Edit` method, which processes the posted movie values:

```
// POST: Movies/Edit/5
// To protect from overposting attacks, please enable the specific properties you want to bind to, for
// more details see http://go.microsoft.com/fwlink/?LinkId=317598.
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction("Index");
    }
    return View(movie);
}
```

The `[Bind]` attribute is one way to protect against [over-posting](#). You should only include properties in the `[Bind]` attribute that you want to change. See [Protect your controller from over-posting](#) for more information.

[ViewModels](#) provide an alternative approach to prevent over-posting.

Notice the second `Edit` action method is preceded by the `[HttpPost]` attribute.

```
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction(nameof(Index));
    }
    return View(movie);
}
```

```

// POST: Movies/Edit/5
// To protect from overposting attacks, please enable the specific properties you want to bind to, for
// more details see http://go.microsoft.com/fwlink/?LinkId=317598.
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction("Index");
    }
    return View(movie);
}

```

The `[HttpPost]` attribute specifies that this `Edit` method can be invoked *only* for `POST` requests. You could apply the `[HttpGet]` attribute to the first edit method, but that's not necessary because `[HttpGet]` is the default.

The `[ValidateAntiForgeryToken]` attribute is used to [prevent forgery of a request](#) and is paired up with an anti-forgery token generated in the edit view file (`Views/Movies/Edit.cshtml`). The edit view file generates the anti-forgery token with the [Form Tag Helper](#).

```
<form asp-action="Edit">
```

The [Form Tag Helper](#) generates a hidden anti-forgery token that must match the `[ValidateAntiForgeryToken]` generated anti-forgery token in the `Edit` method of the Movies controller. For more information, see [Anti-Request Forgery](#).

The `[HttpGet Edit]` method takes the movie `ID` parameter, looks up the movie using the Entity Framework `SingleOrDefaultAsync` method, and returns the selected movie to the Edit view. If a movie cannot be found, `NotFound` (HTTP 404) is returned.

```
// GET: Movies/Edit/5
public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie.FindAsync(id);
    if (movie == null)
    {
        return NotFound();
    }
    return View(movie);
}
```

```
// GET: Movies/Edit/5
public async Task<IActionResult> Edit(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }
    return View(movie);
}
```

When the scaffolding system created the Edit view, it examined the `Movie` class and created code to render `<label>` and `<input>` elements for each property of the class. The following example shows the Edit view that was generated by the Visual Studio scaffolding system:

```

@model MvcMovie.Models.Movie

 @{
     ViewData["Title"] = "Edit";
 }

<h2>Edit</h2>

<form asp-action="Edit">
    <div class="form-horizontal">
        <h4>Movie</h4>
        <hr />
        <div asp-validation-summary="ModelOnly" class="text-danger"></div>
        <input type="hidden" asp-for="ID" />
        <div class="form-group">
            <label asp-for="Title" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Title" class="form-control" />
                <span asp-validation-for="Title" class="text-danger"></span>
            </div>
        </div>
        <div class="form-group">
            <label asp-for="ReleaseDate" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="ReleaseDate" class="form-control" />
                <span asp-validation-for="ReleaseDate" class="text-danger"></span>
            </div>
        </div>
        <div class="form-group">
            <label asp-for="Genre" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Genre" class="form-control" />
                <span asp-validation-for="Genre" class="text-danger"></span>
            </div>
        </div>
        <div class="form-group">
            <label asp-for="Price" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Price" class="form-control" />
                <span asp-validation-for="Price" class="text-danger"></span>
            </div>
        </div>
        <div class="form-group">
            <div class="col-md-offset-2 col-md-10">
                <input type="submit" value="Save" class="btn btn-default" />
            </div>
        </div>
    </div>
</form>

<div>
    <a asp-action="Index">Back to List</a>
</div>

@section Scripts {
    @{await Html.RenderPartialAsync("_ValidationScriptsPartial");}
}

```

Notice how the view template has a `@model MvcMovie.Models.Movie` statement at the top of the file.

`@model MvcMovie.Models.Movie` specifies that the view expects the model for the view template to be of type `Movie`.

The scaffolded code uses several Tag Helper methods to streamline the HTML markup. The - [Label Tag Helper](#) displays the name of the field ("Title", "ReleaseDate", "Genre", or "Price"). The [Input Tag Helper](#) renders an HTML `<input>` element. The [Validation Tag Helper](#) displays any validation messages associated with that property.

Run the application and navigate to the `/Movies` URL. Click an **Edit** link. In the browser, view the source for the page. The generated HTML for the `<form>` element is shown below.

```
<form action="/Movies/Edit/7" method="post">
    <div class="form-horizontal">
        <h4>Movie</h4>
        <hr />
        <div class="text-danger" />
        <input type="hidden" data-val="true" data-val-required="The ID field is required." id="ID" name="ID" value="7" />
        <div class="form-group">
            <label class="control-label col-md-2" for="Genre" />
            <div class="col-md-10">
                <input class="form-control" type="text" id="Genre" name="Genre" value="Western" />
                <span class="text-danger field-validation-valid" data-valmsg-for="Genre" data-valmsg-replace="true"></span>
            </div>
        </div>
        <div class="form-group">
            <label class="control-label col-md-2" for="Price" />
            <div class="col-md-10">
                <input class="form-control" type="text" data-val="true" data-val-number="The field Price must be a number." data-val-required="The Price field is required." id="Price" name="Price" value="3.99" />
                <span class="text-danger field-validation-valid" data-valmsg-for="Price" data-valmsg-replace="true"></span>
            </div>
        </div>
        <!-- Markup removed for brevity -->
        <div class="form-group">
            <div class="col-md-offset-2 col-md-10">
                <input type="submit" value="Save" class="btn btn-default" />
            </div>
        </div>
    </div>
    <input name="__RequestVerificationToken" type="hidden" value="CfDJ8Inyxp63fRFqUePGvuI5jGZsloJu1L7X9le1gy7NCI1SduCRx9jDQC1rV9pOTTmqUyXnJBXhmrjcUVDJyDUMm7-MF_9rK8aAZdRdl0ri7FmKVkRe_2v5LIHGKFcTjPrWPYnc9AdSbomki0SaTEg7RU" />
</form>
```

The `<input>` elements are in an `HTML <form>` element whose `action` attribute is set to post to the `/Movies/Edit/id` URL. The form data will be posted to the server when the `Save` button is clicked. The last line before the closing `</form>` element shows the hidden **XSRF** token generated by the [Form Tag Helper](#).

## Processing the POST Request

The following listing shows the `[HttpPost]` version of the `Edit` action method.

```
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction(nameof(Index));
    }
    return View(movie);
}
```

```

// POST: Movies/Edit/5
// To protect from overposting attacks, please enable the specific properties you want to bind to, for
// more details see http://go.microsoft.com/fwlink/?LinkId=317598.
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Edit(int id, [Bind("ID,Title,ReleaseDate,Genre,Price")] Movie movie)
{
    if (id != movie.ID)
    {
        return NotFound();
    }

    if (ModelState.IsValid)
    {
        try
        {
            _context.Update(movie);
            await _context.SaveChangesAsync();
        }
        catch (DbUpdateConcurrencyException)
        {
            if (!MovieExists(movie.ID))
            {
                return NotFound();
            }
            else
            {
                throw;
            }
        }
        return RedirectToAction("Index");
    }
    return View(movie);
}

```

The `[ValidateAntiForgeryToken]` attribute validates the hidden [XSRF](#) token generated by the anti-forgery token generator in the [Form Tag Helper](#)

The [model binding](#) system takes the posted form values and creates a `Movie` object that's passed as the `movie` parameter. The `ModelState.IsValid` method verifies that the data submitted in the form can be used to modify (edit or update) a `Movie` object. If the data is valid it's saved. The updated (edited) movie data is saved to the database by calling the `SaveChangesAsync` method of database context. After saving the data, the code redirects the user to the `Index` action method of the `MoviesController` class, which displays the movie collection, including the changes just made.

Before the form is posted to the server, client side validation checks any validation rules on the fields. If there are any validation errors, an error message is displayed and the form isn't posted. If JavaScript is disabled, you won't have client side validation but the server will detect the posted values that are not valid, and the form values will be redisplayed with error messages. Later in the tutorial we examine [Model Validation](#) in more detail. The [Validation Tag Helper](#) in the `Views/Movies/Edit.cshtml` view template takes care of displaying appropriate error messages.

All the `[HttpGet]` methods in the movie controller follow a similar pattern. They get a movie object (or list of objects, in the case of `Index`), and pass the object (model) to the view. The `Create` method passes an empty movie object to the `Create` view. All the methods that create, edit, delete, or otherwise modify data do so in the `[HttpPost]` overload of the method. Modifying data in an `HTTP GET` method is a security risk. Modifying data in an `HTTP GET` method also violates HTTP best practices and the architectural `REST` pattern, which specifies that GET requests shouldn't change the state of your application. In other words, performing a GET operation should be a safe operation that has no side effects and doesn't modify your persisted data.

[PREVIOUS - WORKING WITH  
SQLITE](#)

[NEXT - ADD  
SEARCH](#)

# Add search to an ASP.NET Core MVC app

6/26/2018 • 7 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section you add search capability to the `Index` action method that lets you search movies by *genre* or *name*.

Update the `Index` method with the following code:

```
public async Task<IActionResult> Index(string searchString)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    return View(await movies.ToListAsync());
}
```

The first line of the `Index` action method creates a [LINQ](#) query to select the movies:

```
var movies = from m in _context.Movie
             select m;
```

The query is *only* defined at this point, it has **not** been run against the database.

If the `searchString` parameter contains a string, the movies query is modified to filter on the value of the search string:

```
if (!String.IsNullOrEmpty(searchString))
{
    movies = movies.Where(s => s.Title.Contains(searchString));
}
```

The `s => s.Title.Contains()` code above is a [Lambda Expression](#). Lambdas are used in method-based [LINQ](#) queries as arguments to standard query operator methods such as the `Where` method or `Contains` (used in the code above). LINQ queries are not executed when they're defined or when they're modified by calling a method such as `Where`, `Contains` or `OrderBy`. Rather, query execution is deferred. That means that the evaluation of an expression is delayed until its realized value is actually iterated over or the `ToListAsync` method is called. For more information about deferred query execution, see [Query Execution](#).

Note: The `Contains` method is run on the database, not in the c# code shown above. The case sensitivity on the query depends on the database and the collation. On SQL Server, `Contains` maps to [SQL LIKE](#), which is case insensitive. In SQLite, with the default collation, it's case sensitive.

Navigate to `/Movies/Index`. Append a query string such as `?searchString=Ghost` to the URL. The filtered movies are displayed.

Title	Release Date	Genre	Price
Ghostbusters	3/13/1984	Comedy	8.99
Ghostbusters 2	2/23/1986	Comedy	9.99

If you change the signature of the `Index` method to have a parameter named `id`, the `id` parameter will match the optional `{id}` placeholder for the default routes set in `Startup.cs`.

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

Note: SQLite is case sensitive, so you'll need to search for "Ghost" and not "ghost".

The previous `Index` method:

```
public async Task<IActionResult> Index(string searchString)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    return View(await movies.ToListAsync());
}
```

The updated `Index` method with `id` parameter:

```
public async Task<IActionResult> Index(string id)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(id))
    {
        movies = movies.Where(s => s.Title.Contains(id));
    }

    return View(await movies.ToListAsync());
}
```

You can now pass the search title as route data (a URL segment) instead of as a query string value.

Mvc Movie

# Index

Create New

Genre	Price	Release Date	Title	
Comedy	8.99	3/13/1984	Ghostbusters	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	9.99	2/23/1986	Ghostbusters 2	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

© 2015 - MvcMovie

However, you can't expect users to modify the URL every time they want to search for a movie. So now you'll add UI elements to help them filter movies. If you changed the signature of the `Index` method to test how to pass the route-bound `ID` parameter, change it back so that it takes a parameter named `searchString`:

```
public async Task<IActionResult> Index(string searchString)
{
    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    return View(await movies.ToListAsync());
}
```

Open the `Views/Movies/Index.cshtml` file, and add the `<form>` markup highlighted below:

```
ViewData["Title"] = "Index";
}

<h2>Index</h2>

<p>
    <a asp-action="Create">Create New</a>
</p>

<form asp-controller="Movies" asp-action="Index">
    <p>
        Title: <input type="text" name="SearchString">
        <input type="submit" value="Filter" />
    </p>
</form>

<table class="table">
    <thead>
```

The HTML `<form>` tag uses the [Form Tag Helper](#), so when you submit the form, the filter string is posted to the `Index` action of the movies controller. Save your changes and then test the filter.

Genre	Price	Release Date	Title	
Romantic Comedy	7.99	1/11/1989	When Harry Met Sally	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	8.99	3/13/1984	Ghostbusters	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	9.99	2/23/1986	Ghostbusters 2	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Western	3.99	4/15/1959	Rio Bravo	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

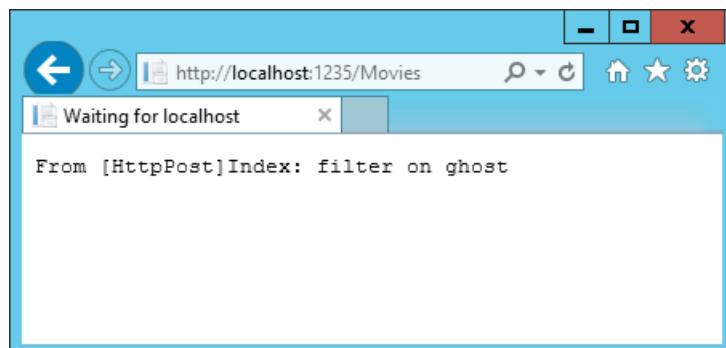

There's no `[HttpPost]` overload of the `Index` method as you might expect. You don't need it, because the method isn't changing the state of the app, just filtering data.

You could add the following `[HttpPost] Index` method.

```
[HttpPost]
public string Index(string searchString, bool notUsed)
{
    return "From [HttpPost]Index: filter on " + searchString;
}
```

The `notUsed` parameter is used to create an overload for the `Index` method. We'll talk about that later in the tutorial.

If you add this method, the action invoker would match the `[HttpPost] Index` method, and the `[HttpPost] Index` method would run as shown in the image below.

However, even if you add this `[HttpPost]` version of the `Index` method, there's a limitation in how this has all been implemented. Imagine that you want to bookmark a particular search or you want to send a link to friends that they can click in order to see the same filtered list of movies. Notice that the URL for the HTTP POST request is the same as the URL for the GET request (`localhost:xxxx/Movies/Index`) -- there's no search information in the

URL. The search string information is sent to the server as a [form field value](#). You can verify that with the browser Developer tools or the excellent [Fiddler tool](#). The image below shows the Chrome browser Developer tools:

The screenshot shows the Chrome Developer Tools Network tab with a red box highlighting the 'Network' tab itself. Below it, another red box highlights the 'Movies' entry in the list of requests. The 'General' section of the request details is also highlighted with a red box, showing the Request URL, Method, Status Code (200 OK), and other headers like Cache-Control, Content-Type, Date, Pragma, Server, and Transfer-Encoding. The 'Form Data' section is also highlighted with a red box, showing the 'SearchString' parameter with the value 'Ghost' and a long 'RequestVerificationToken' parameter.

You can see the search parameter and [XSRF](#) token in the request body. Note, as mentioned in the previous tutorial, the [Form Tag Helper](#) generates an [XSRF](#) anti-forgery token. We're not modifying data, so we don't need to validate the token in the controller method.

Because the search parameter is in the request body and not the URL, you can't capture that search information to bookmark or share with others. We'll fix this by specifying the request should be [HTTP GET](#).

Change the `<form>` tag in the `Views\movie\Index.cshtml` Razor view to specify `method="get"`:

```
<form asp-controller="Movies" asp-action="Index" method="get">
```

Now when you submit a search, the URL contains the search query string. Searching will also go to the `HttpGet Index` action method, even if you have a `HttpPost Index` method.

Genre	Price	Release Date	Title	
Comedy	8.99	3/13/1984	Ghostbusters	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>
Comedy	9.99	2/23/1986	Ghostbusters 2	<a href="#">Edit</a>   <a href="#">Details</a>   <a href="#">Delete</a>

The following markup shows the change to the `form` tag:

```
<form asp-controller="Movies" asp-action="Index" method="get">
```

## Adding Search by genre

Add the following `MovieGenreViewModel` class to the *Models* folder:

```
using Microsoft.AspNetCore.Mvc.Rendering;
using System.Collections.Generic;

namespace MvcMovie.Models
{
    public class MovieGenreViewModel
    {
        public List<Movie> movies;
        public SelectList genres;
        public string movieGenre { get; set; }
    }
}
```

The movie-genre view model will contain:

- A list of movies.
- A `selectList` containing the list of genres. This will allow the user to select a genre from the list.
- `movieGenre`, which contains the selected genre.

Replace the `Index` method in `MoviesController.cs` with the following code:

```

// Requires using Microsoft.AspNetCore.Mvc.Rendering;
public async Task<IActionResult> Index(string movieGenre, string searchString)
{
    // Use LINQ to get list of genres.
    IQueryable<string> genreQuery = from m in _context.Movie
                                         orderby m.Genre
                                         select m.Genre;

    var movies = from m in _context.Movie
                 select m;

    if (!String.IsNullOrEmpty(searchString))
    {
        movies = movies.Where(s => s.Title.Contains(searchString));
    }

    if (!String.IsNullOrEmpty(movieGenre))
    {
        movies = movies.Where(x => x.Genre == movieGenre);
    }

    var movieGenreVM = new MovieGenreViewModel();
    movieGenreVM.genres = new SelectList(await genreQuery.Distinct().ToListAsync());
    movieGenreVM.movies = await movies.ToListAsync();

    return View(movieGenreVM);
}

```

The following code is a `LINQ` query that retrieves all the genres from the database.

```

// Use LINQ to get list of genres.
IQueryable<string> genreQuery = from m in _context.Movie
                                         orderby m.Genre
                                         select m.Genre;

```

The `SelectList` of genres is created by projecting the distinct genres (we don't want our select list to have duplicate genres).

```
movieGenreVM.genres = new SelectList(await genreQuery.Distinct().ToListAsync())
```

## Adding search by genre to the Index view

Update `Index.cshtml` as follows:

```

@model MvcMovie.Models.MovieGenreViewModel

 @{
     ViewData["Title"] = "Index";
 }

<h2>Index</h2>

<p>
    <a asp-action="Create">Create New</a>
</p>

<form asp-controller="Movies" asp-action="Index" method="get">
    <p>
        <select asp-for="movieGenre" asp-items="Model.genres">
            <option value="">All</option>
        </select>

        Title: <input type="text" name="SearchString">
        <input type="submit" value="Filter" />
    </p>
</form>

<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Title)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].ReleaseDate)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Genre)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Price)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
        @foreach (var item in Model.movies)
        {
            <tr>
                <td>
                    @Html.DisplayFor(modelItem => item.Title)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.ReleaseDate)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Genre)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Price)
                </td>
                <td>
                    <a asp-action="Edit" asp-route-id="@item.ID">Edit</a> |
                    <a asp-action="Details" asp-route-id="@item.ID">Details</a> |
                    <a asp-action="Delete" asp-route-id="@item.ID">Delete</a>
                </td>
            </tr>
        }
    </tbody>
</table>

```

Examine the lambda expression used in the following HTML Helper:

```
@Html.DisplayNameFor(model => model.movies[0].Title)
```

In the preceding code, the `DisplayNameFor` HTML Helper inspects the `Title` property referenced in the lambda expression to determine the display name. Since the lambda expression is inspected rather than evaluated, you don't receive an access violation when `model`, `model.movies`, or `model.movies[0]` are `null` or empty. When the lambda expression is evaluated (for example, `@Html.DisplayFor(modelItem => item.Title)`), the model's property values are evaluated.

Test the app by searching by genre, by movie title, and by both.

[PREVIOUS - CONTROLLER METHODS AND  
VIEWS](#)

[NEXT - ADD A  
FIELD](#)

# Add a new field to an ASP.NET Core MVC app

6/26/2018 • 3 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

This tutorial will add a new field to the `Movies` table. We'll drop the database and create a new one when we change the schema (add a new field). This workflow works well early in development when we don't have any production data to preserve.

Once your app is deployed and you have data that you need to preserve, you can't drop your DB when you need to change the schema. Entity Framework [Code First Migrations](#) allows you to update your schema and migrate the database without losing data. Migrations is a popular feature when using SQL Server, but SQLite doesn't support many migration schema operations, so only very simple migrations are possible. See [SQLite Limitations](#) for more information.

## Adding a Rating Property to the Movie Model

Open the `Models/Movie.cs` file and add a `Rating` property:

```
public class Movie
{
    public int ID { get; set; }
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }
    public string Genre { get; set; }

    [Column(TypeName = "decimal(18, 2)")]
    public decimal Price { get; set; }
    public string Rating { get; set; }
}
```

```
public class Movie
{
    public int ID { get; set; }
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }
    public string Genre { get; set; }
    public decimal Price { get; set; }
    public string Rating { get; set; }
}
```

Because you've added a new field to the `Movie` class, you also need to update the binding whitelist so this new property will be included. In `MoviesController.cs`, update the `[Bind]` attribute for both the `Create` and `Edit` action methods to include the `Rating` property:

```
[Bind("ID,Title,ReleaseDate,Genre,Price,Rating")]
```

You also need to update the view templates in order to display, create, and edit the new `Rating` property in the browser view.

Edit the `/Views/Movies/Index.cshtml` file and add a `Rating` field:

```
<table class="table">
    <thead>
        <tr>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Title)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].ReleaseDate)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Genre)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Price)
            </th>
            <th>
                @Html.DisplayNameFor(model => model.movies[0].Rating)
            </th>
            <th></th>
        </tr>
    </thead>
    <tbody>
        @foreach (var item in Model.movies)
        {
            <tr>
                <td>
                    @Html.DisplayFor(modelItem => item.Title)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.ReleaseDate)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Genre)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Price)
                </td>
                <td>
                    @Html.DisplayFor(modelItem => item.Rating)
                </td>
                <td>
```

Update the `/Views/Movies/Create.cshtml` with a `Rating` field.

The app won't work until we update the DB to include the new field. If you run it now, you'll get the following `SqliteException`:

```
SqliteException: SQLite Error 1: 'no such column: m.Rating'.
```

You're seeing this error because the updated Movie model class is different than the schema of the Movie table of the existing database. (There's no `Rating` column in the database table.)

There are a few approaches to resolving the error:

1. Drop the database and have the Entity Framework automatically re-create the database based on the new model class schema. With this approach, you lose existing data in the database — so you can't do this with a production database! Using an initializer to automatically seed a database with test data is often a

productive way to develop an app.

2. Manually modify the schema of the existing database so that it matches the model classes. The advantage of this approach is that you keep your data. You can make this change either manually or by creating a database change script.
3. Use Code First Migrations to update the database schema.

For this tutorial, we'll drop and re-create the database when the schema changes. Run the following command from a terminal to drop the db:

```
dotnet ef database drop
```

Update the `SeedData` class so that it provides a value for the new column. A sample change is shown below, but you'll want to make this change for each `new Movie`.

```
new Movie
{
    Title = "When Harry Met Sally",
    ReleaseDate = DateTime.Parse("1989-1-11"),
    Genre = "Romantic Comedy",
    Rating = "R",
    Price = 7.99M
},
```

Add the `Rating` field to the `Edit`, `Details`, and `Delete` view.

Run the app and verify you can create/edit/display movies with a `Rating` field. templates.

SEARCH

NEXT - ADD  
VALIDATION

# Add validation to an ASP.NET Core MVC app

6/26/2018 • 10 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

In this section you'll add validation logic to the `Movie` model, and you'll ensure that the validation rules are enforced any time a user creates or edits a movie.

## Keeping things DRY

One of the design tenets of MVC is [DRY](#) ("Don't Repeat Yourself"). ASP.NET MVC encourages you to specify functionality or behavior only once, and then have it be reflected everywhere in an app. This reduces the amount of code you need to write and makes the code you do write less error prone, easier to test, and easier to maintain.

The validation support provided by MVC and Entity Framework Core Code First is a good example of the DRY principle in action. You can declaratively specify validation rules in one place (in the model class) and the rules are enforced everywhere in the app.

## Adding validation rules to the movie model

Open the `Movie.cs` file. DataAnnotations provides a built-in set of validation attributes that you apply declaratively to any class or property. (It also contains formatting attributes like `DataType` that help with formatting and don't provide any validation.)

Update the `Movie` class to take advantage of the built-in `Required`, `StringLength`, `RegularExpression`, and `Range` validation attributes.

```
public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3)]
    [Required]
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [Range(1, 100)]
    [DataType(DataType.Currency)]
    [Column(TypeName = "decimal(18, 2)")]
    public decimal Price { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z''"\s-]*$")]
    [Required]
    [StringLength(30)]
    public string Genre { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z0-9'''\s-]*$")]
    [StringLength(5)]
    [Required]
    public string Rating { get; set; }
}
```

```

public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3)]
    [Required]
    public string Title { get; set; }

    [Display(Name = "Release Date")]
    [DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [Range(1, 100)]
    [DataType(DataType.Currency)]
    public decimal Price { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z\s-]*$")]
    [Required]
    [StringLength(30)]
    public string Genre { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z0-9\s-]*$")]
    [StringLength(5)]
    [Required]
    public string Rating { get; set; }
}

```

The validation attributes specify behavior that you want to enforce on the model properties they're applied to. The `Required` and `MinimumLength` attributes indicate that a property must have a value; but nothing prevents a user from entering white space to satisfy this validation. The `RegularExpression` attribute is used to limit what characters can be input. In the code above, `Genre` and `Rating` must use only letters (First letter uppercase, white space, numbers and special characters are not allowed). The `Range` attribute constrains a value to within a specified range. The `StringLength` attribute lets you set the maximum length of a string property, and optionally its minimum length. Value types (such as `decimal`, `int`, `float`, `DateTime`) are inherently required and don't need the `[Required]` attribute.

Having validation rules automatically enforced by ASP.NET helps make your app more robust. It also ensures that you can't forget to validate something and inadvertently let bad data into the database.

## Validation Error UI in MVC

Run the app and navigate to the Movies controller.

Tap the **Create New** link to add a new movie. Fill out the form with some invalid values. As soon as jQuery client side validation detects the error, it displays an error message.

The screenshot shows a browser window titled "Create - Movie App" with the URL "localhost:5000/Movies/Create". The page is titled "Create Movie". It contains a form with the following fields and validation errors:

- Title**: An input field with a placeholder icon. Error message: "The field Title must be a string with a minimum length of 3 and a maximum length of 60."
- Release Date**: An input field with a placeholder "mm/dd/yyyy".
- Genre**: An input field. Error message: "The Genre field is required."
- Price**: An input field containing "z". Error message: "The field Price must be a number."
- Rating**: An input field. Error message: "The field Rating must match the regular expression '^([A-Z]+[a-zA-Z-\s]\*)\$'."

At the bottom of the form are two buttons: "Create" and "Back to List".

#### NOTE

You may not be able to enter decimal commas in the `Price` field. To support [jQuery validation](#) for non-US English locales that use a comma (",") for a decimal point, and non US-English date formats, you must take steps to globalize your app. This [GitHub issue 4076](#) for instructions on adding decimal comma.

Notice how the form has automatically rendered an appropriate validation error message in each field containing an invalid value. The errors are enforced both client-side (using JavaScript and jQuery) and server-side (in case a user has JavaScript disabled).

A significant benefit is that you didn't need to change a single line of code in the `MoviesController` class or in the `Create.cshtml` view in order to enable this validation UI. The controller and views you created earlier in this tutorial automatically picked up the validation rules that you specified by using validation attributes on the properties of the `Movie` model class. Test validation using the `Edit` action method, and the same validation is applied.

The form data isn't sent to the server until there are no client side validation errors. You can verify this by putting a break point in the `HTTP Post` method, by using the [Fiddler tool](#), or the [F12 Developer tools](#).

## How validation works

You might wonder how the validation UI was generated without any updates to the code in the controller or views. The following code shows the two `Create` methods.

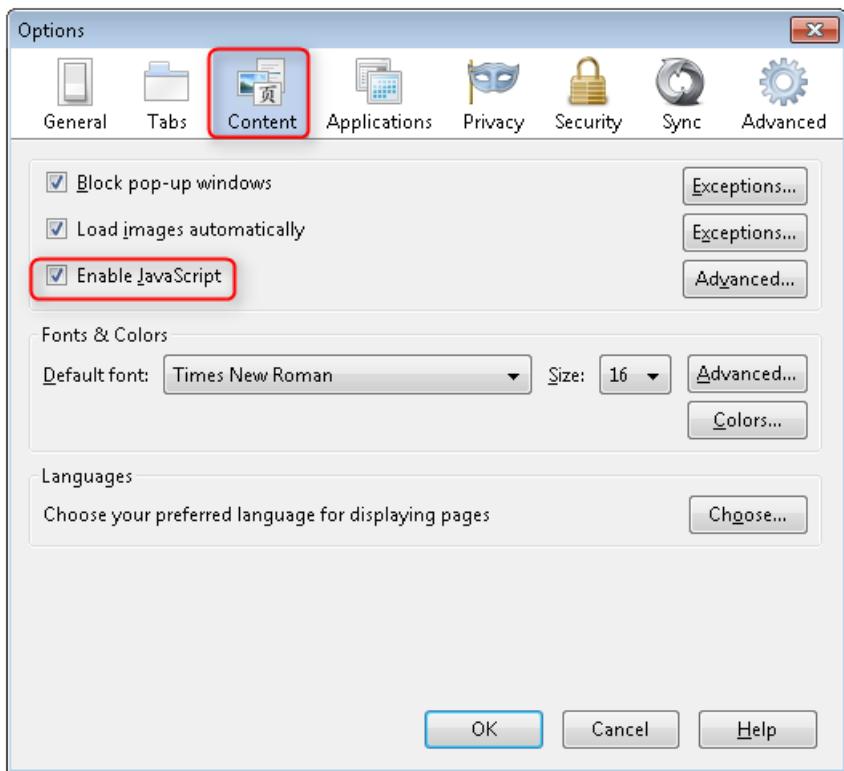

```
// GET: Movies/Create
public IActionResult Create()
{
    return View();
}

// POST: Movies/Create
[HttpPost]
[ValidateAntiForgeryToken]
public async Task<IActionResult> Create(
    [Bind("ID,Title,ReleaseDate,Genre,Price, Rating")] Movie movie)
{
    if (ModelState.IsValid)
    {
        _context.Add(movie);
        await _context.SaveChangesAsync();
        return RedirectToAction("Index");
    }
    return View(movie);
}
```

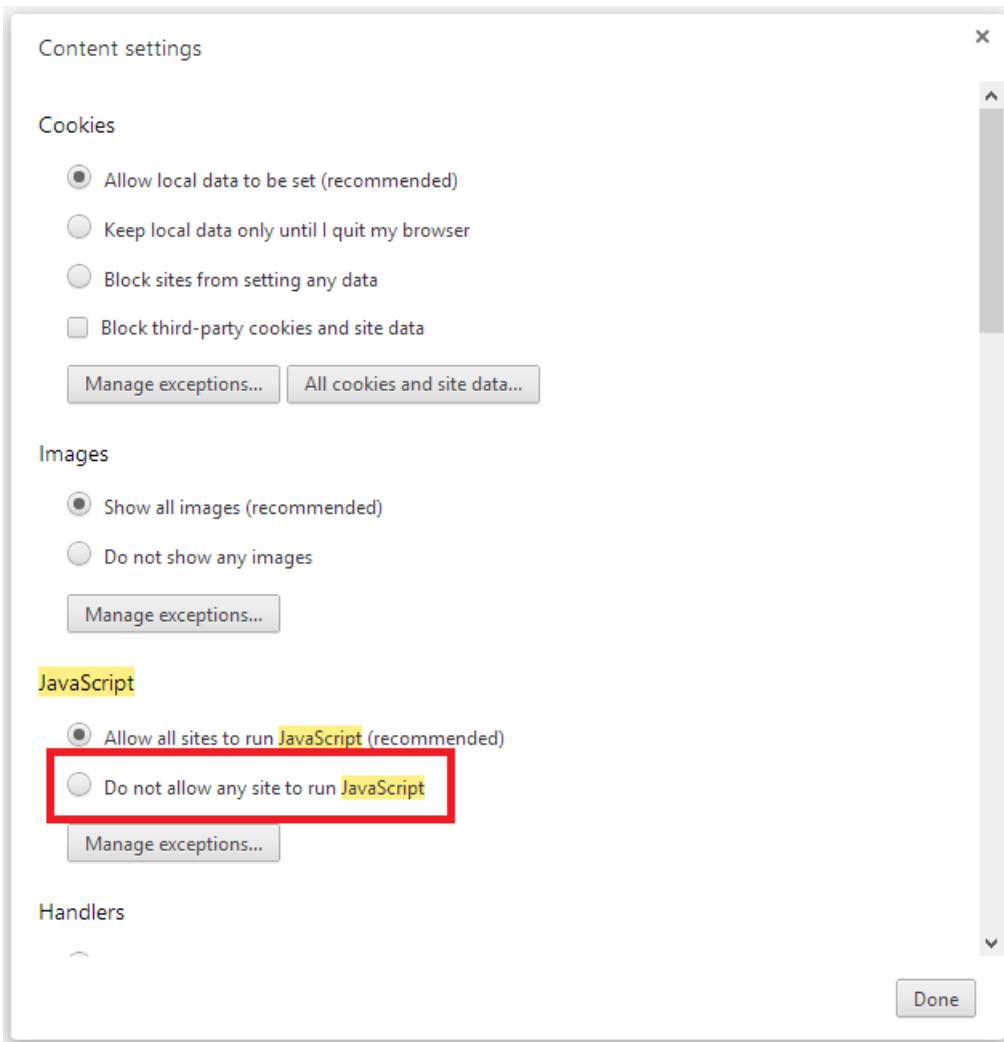

The first (HTTP GET) `Create` action method displays the initial Create form. The second (`[HttpPost]`) version handles the form post. The second `Create` method (The `[HttpPost]` version) calls `ModelState.IsValid` to check whether the movie has any validation errors. Calling this method evaluates any validation attributes that have been applied to the object. If the object has validation errors, the `Create` method re-displays the form. If there are no errors, the method saves the new movie in the database. In our movie example, the form isn't posted to the server when there are validation errors detected on the client side; the second `Create` method is never called when there are client side validation errors. If you disable JavaScript in your browser, client validation is disabled and you can test the HTTP POST `Create` method `ModelState.IsValid` detecting any validation errors.

You can set a break point in the `[HttpPost] Create` method and verify the method is never called, client side validation won't submit the form data when validation errors are detected. If you disable JavaScript in your browser, then submit the form with errors, the break point will be hit. You still get full validation without JavaScript.

The following image shows how to disable JavaScript in the FireFox browser.

The following image shows how to disable JavaScript in the Chrome browser.

After you disable JavaScript, post invalid data and step through the debugger.

```
74     // POST: Movies/Create
75     // To protect from overposting attacks, please enable t
76     // more details see http://go.microsoft.com/fwlink/?LinkID=142072
77     [HttpPost]
78     [ValidateAntiForgeryToken]
79     0 references
80     public async Task<IActionResult> Create([Bind("ID,Title")]
81     {
82         if (ModelState.IsValid)
83         {
84             _context.Add(movie);
85             await _context.SaveChangesAsync();
86             return RedirectToAction("Index");
87         }
88         return View(movie);
89     }

```

Below is portion of the `Create.cshtml` view template that you scaffolded earlier in the tutorial. It's used by the action methods shown above both to display the initial form and to redisplay it in the event of an error.

```
<form asp-action="Create">
    <div class="form-horizontal">
        <h4>Movie</h4>
        <hr />

        <div asp-validation-summary="ModelOnly" class="text-danger"></div>
        <div class="form-group">
            <label asp-for="Title" class="col-md-2 control-label"></label>
            <div class="col-md-10">
                <input asp-for="Title" class="form-control" />
                <span asp-validation-for="Title" class="text-danger"></span>
            </div>
        </div>

        @*Markup removed for brevity.*@
    </div>
</form>
```

The [Input Tag Helper](#) uses the [DataAnnotations](#) attributes and produces HTML attributes needed for jQuery Validation on the client side. The [Validation Tag Helper](#) displays validation errors. See [Validation](#) for more information.

What's really nice about this approach is that neither the controller nor the `Create` view template knows anything about the actual validation rules being enforced or about the specific error messages displayed. The validation rules and the error strings are specified only in the `Movie` class. These same validation rules are automatically applied to the `Edit` view and any other views templates you might create that edit your model.

When you need to change validation logic, you can do so in exactly one place by adding validation attributes to the model (in this example, the `Movie` class). You won't have to worry about different parts of the application being inconsistent with how the rules are enforced — all validation logic will be defined in one place and used everywhere. This keeps the code very clean, and makes it easy to maintain and evolve. And it means that you'll be fully honoring the DRY principle.

## Using DataType Attributes

Open the `Movie.cs` file and examine the `Movie` class. The `System.ComponentModel.DataAnnotations` namespace provides formatting attributes in addition to the built-in set of validation attributes. We've already applied a `DataType` enumeration value to the release date and to the price fields. The following code shows the `ReleaseDate` and `Price` properties with the appropriate `DataType` attribute.

```
[Display(Name = "Release Date")]
[DataType(DataType.Date)]
public DateTime ReleaseDate { get; set; }

[Range(1, 100)]
[DataType(DataType.Currency)]
public decimal Price { get; set; }
```

The `DataType` attributes only provide hints for the view engine to format the data (and supplies elements/attributes such as `<a>` for URL's and `<a href="mailto:EmailAddress.com">` for email). You can use the `RegularExpression` attribute to validate the format of the data. The `DataType` attribute is used to specify a data type that's more specific than the database intrinsic type, they're not validation attributes. In this case we only want to keep track of the date, not the time. The `DataType` Enumeration provides for many data types, such as Date, Time, PhoneNumber, Currency, EmailAddress and more. The `DataType` attribute can also enable the application to automatically provide type-specific features. For example, a `mailto:` link can be created for `DataType.EmailAddress`, and a date selector can be provided for `DataType.Date` in browsers that support HTML5. The `DataType` attributes emits HTML 5 `data-` (pronounced data dash) attributes that HTML 5 browsers can understand. The `DataType` attributes do **not** provide any validation.

`DataType.Date` doesn't specify the format of the date that's displayed. By default, the data field is displayed according to the default formats based on the server's `CultureInfo`.

The `DisplayFormat` attribute is used to explicitly specify the date format:

```
[DisplayFormat(DataFormatString = "{0:yyyy-MM-dd}", ApplyFormatInEditMode = true)]
public DateTime ReleaseDate { get; set; }
```

The `ApplyFormatInEditMode` setting specifies that the formatting should also be applied when the value is displayed in a text box for editing. (You might not want that for some fields — for example, for currency values, you probably don't want the currency symbol in the text box for editing.)

You can use the `DisplayFormat` attribute by itself, but it's generally a good idea to use the `DataType` attribute. The `DataType` attribute conveys the semantics of the data as opposed to how to render it on a screen, and provides the following benefits that you don't get with `DisplayFormat`:

- The browser can enable HTML5 features (for example to show a calendar control, the locale-appropriate currency symbol, email links, etc.)
- By default, the browser will render data using the correct format based on your locale.
- The `DataType` attribute can enable MVC to choose the right field template to render the data (the `DisplayFormat` if used by itself uses the string template).

#### NOTE

jQuery validation doesn't work with the `Range` attribute and `DateTime`. For example, the following code will always display a client side validation error, even when the date is in the specified range:

```
[Range(typeof(DateTime), "1/1/1966", "1/1/2020")]
```

You will need to disable jQuery date validation to use the `Range` attribute with `DateTime`. It's generally not a good practice to compile hard dates in your models, so using the `Range` attribute and `DateTime` is discouraged.

The following code shows combining attributes on one line:

```

public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3)]
    public string Title { get; set; }

    [Display(Name = "Release Date"), DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z\s-]*$"), Required, StringLength(30)]
    public string Genre { get; set; }

    [Range(1, 100), DataType(DataType.Currency)]
    [Column(TypeName = "decimal(18, 2)")]
    public decimal Price { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z0-9\s-]*$"), StringLength(5)]
    public string Rating { get; set; }
}

```

```

public class Movie
{
    public int ID { get; set; }

    [StringLength(60, MinimumLength = 3), Required]
    public string Title { get; set; }

    [Display(Name = "Release Date"), DataType(DataType.Date)]
    public DateTime ReleaseDate { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z\s-]*$"), Required, StringLength(30)]
    public string Genre { get; set; }

    [Range(1, 100), DataType(DataType.Currency)]
    public decimal Price { get; set; }

    [RegularExpression(@"^[A-Z]+[a-zA-Z0-9\s-]*$"), Required, StringLength(5)]
    public string Rating { get; set; }
}

```

In the next part of the series, we'll review the application and make some improvements to the automatically generated `Details` and `Delete` methods.

METHODS

# Examine the Details and Delete methods of an ASP.NET Core app

6/21/2018 • 3 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

Open the Movie controller and examine the `Details` method:

```
// GET: Movies/Details/5
public async Task<IActionResult> Details(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .FirstOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}
```

```
// GET: Movies/Details/5
public async Task<IActionResult> Details(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .SingleOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}
```

The MVC scaffolding engine that created this action method adds a comment showing an HTTP request that invokes the method. In this case it's a GET request with three URL segments, the `Movies` controller, the `Details` method and an `id` value. Recall these segments are defined in *Startup.cs*.

```
app.UseMvc(routes =>
{
    routes.MapRoute(
        name: "default",
        template: "{controller=Home}/{action=Index}/{id?}");
});
```

EF makes it easy to search for data using the `SingleOrDefaultAsync` method. An important security feature built into the method is that the code verifies that the search method has found a movie before it tries to do anything with it. For example, a hacker could introduce errors into the site by changing the URL created by the links from `http://localhost:xxxx/Movies/Details/1` to something like `http://localhost:xxxx/Movies/Details/12345` (or some other value that doesn't represent an actual movie). If you didn't check for a null movie, the app would throw an exception.

Examine the `Delete` and `DeleteConfirmed` methods.

```
// GET: Movies/Delete/5
public async Task<IActionResult> Delete(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .FirstOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}

// POST: Movies/Delete/5
[HttpPost, ActionName("Delete")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> DeleteConfirmed(int id)
{
    var movie = await _context.Movie.FindAsync(id);
    _context.Movie.Remove(movie);
    await _context.SaveChangesAsync();
    return RedirectToAction(nameof(Index));
}
```

```

// GET: Movies/Delete/5
public async Task<IActionResult> Delete(int? id)
{
    if (id == null)
    {
        return NotFound();
    }

    var movie = await _context.Movie
        .SingleOrDefaultAsync(m => m.ID == id);
    if (movie == null)
    {
        return NotFound();
    }

    return View(movie);
}

// POST: Movies/Delete/5
[HttpPost, ActionName("Delete")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> DeleteConfirmed(int id)
{
    var movie = await _context.Movie.SingleOrDefaultAsync(m => m.ID == id);
    _context.Movie.Remove(movie);
    await _context.SaveChangesAsync();
    return RedirectToAction("Index");
}

```

Note that the `HTTP GET Delete` method doesn't delete the specified movie, it returns a view of the movie where you can submit (`HttpPost`) the deletion. Performing a delete operation in response to a GET request (or for that matter, performing an edit operation, create operation, or any other operation that changes data) opens up a security hole.

The `[HttpPost]` method that deletes the data is named `DeleteConfirmed` to give the HTTP POST method a unique signature or name. The two method signatures are shown below:

```

// GET: Movies/Delete/5
public async Task<IActionResult> Delete(int? id)
{
```

```

// POST: Movies/Delete/5
[HttpPost, ActionName("Delete")]
[ValidateAntiForgeryToken]
public async Task<IActionResult> DeleteConfirmed(int id)
{
```

The common language runtime (CLR) requires overloaded methods to have a unique parameter signature (same method name but different list of parameters). However, here you need two `Delete` methods -- one for GET and one for POST -- that both have the same parameter signature. (They both need to accept a single integer as a parameter.)

There are two approaches to this problem, one is to give the methods different names. That's what the scaffolding mechanism did in the preceding example. However, this introduces a small problem: ASP.NET maps segments of a URL to action methods by name, and if you rename a method, routing normally wouldn't be able to find that method. The solution is what you see in the example, which is to add the `ActionName("Delete")` attribute to the `DeleteConfirmed` method. That attribute performs mapping for the routing system so that a URL that includes `/Delete/` for a POST request will find the `DeleteConfirmed` method.

Another common work around for methods that have identical names and signatures is to artificially change the signature of the POST method to include an extra (unused) parameter. That's what we did in a previous post when we added the `notUsed` parameter. You could do the same thing here for the `[HttpPost] Delete` method:

```
// POST: Movies/Delete/6
[ValidateAntiForgeryToken]
public async Task<IActionResult> Delete(int id, bool notUsed)
```

## Publish to Azure

See [Publish an ASP.NET Core web app to Azure App Service using Visual Studio](#) for instructions on how to publish this app to Azure using Visual Studio. The app can also be published from the [command line](#).

[PREVIOUS](#)

# Create a Web API with ASP.NET Core and Visual Studio for Mac

6/21/2018 • 15 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Mike Wasson](#)

In this tutorial, build a web API for managing a list of "to-do" items. The UI isn't constructed.

There are three versions of this tutorial:

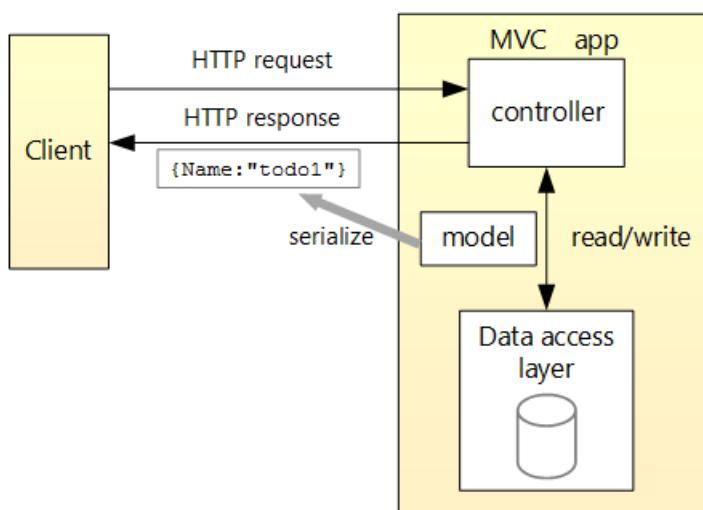

- macOS: Web API with Visual Studio for Mac (This tutorial)
- Windows: [Web API with Visual Studio for Windows](#)
- macOS, Linux, Windows: [Web API with Visual Studio Code](#)

## Overview

This tutorial creates the following API:

API	DESCRIPTION	REQUEST BODY	RESPONSE BODY
GET /api/todo	Get all to-do items	None	Array of to-do items
GET /api/todo/{id}	Get an item by ID	None	To-do item
POST /api/todo	Add a new item	To-do item	To-do item
PUT /api/todo/{id}	Update an existing item	To-do item	None
DELETE /api/todo/{id}	Delete an item	None	None

The following diagram shows the basic design of the app.

- The client is whatever consumes the web API (mobile app, browser, etc.). This tutorial doesn't create a client. [Postman](#) or [curl](#) is used as the client to test the app.
- A *model* is an object that represents the data in the app. In this case, the only model is a to-do item. Models are represented as C# classes, also known as **Plain Old ClR Object** (POCOs).

- A *controller* is an object that handles HTTP requests and creates the HTTP response. This app has a single controller.
- To keep the tutorial simple, the app doesn't use a persistent database. The sample app stores to-do items in an in-memory database.

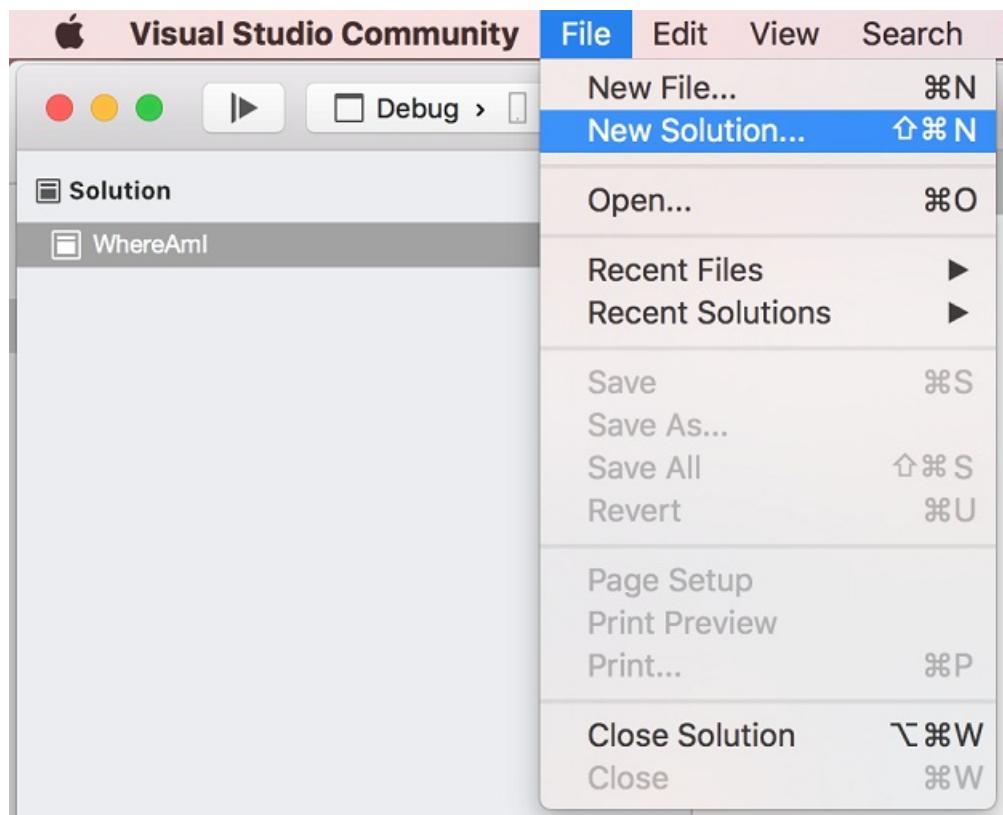

See [Introduction to ASP.NET Core MVC on macOS or Linux](#) for an example that uses a persistent database.

## Prerequisites

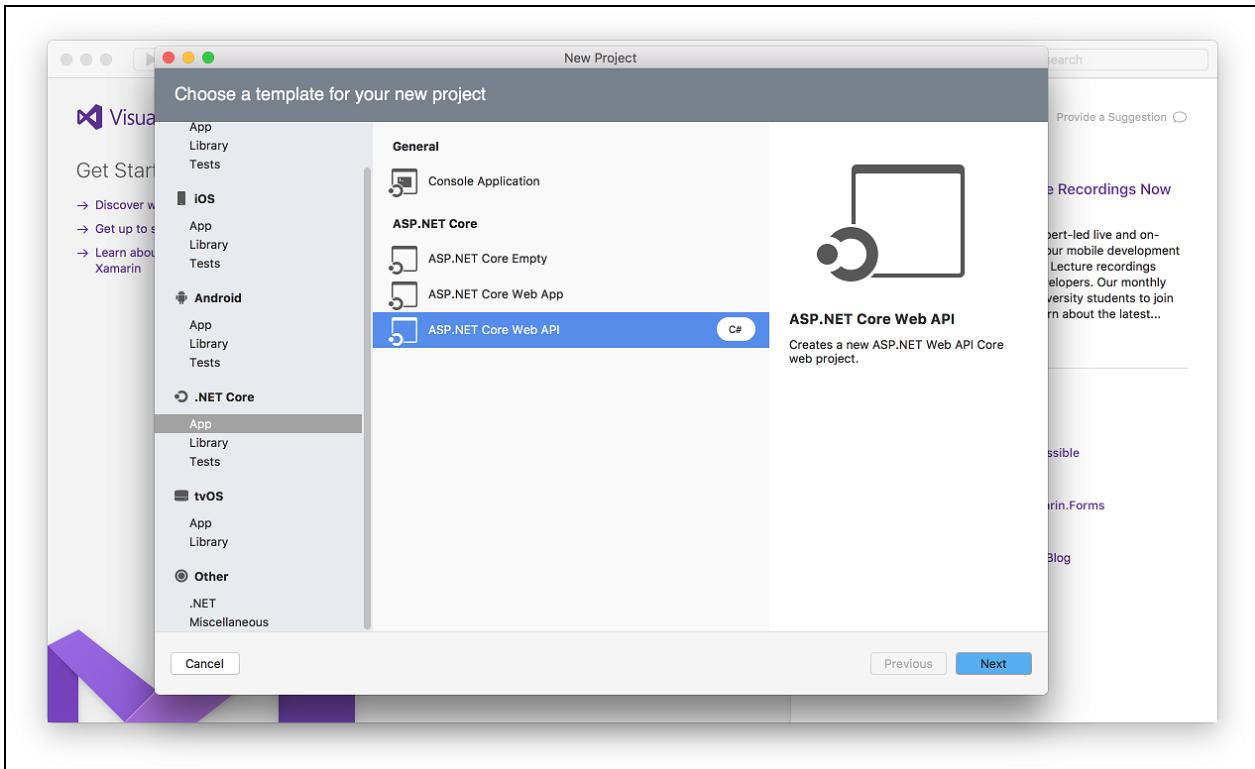

[Visual Studio for Mac](#)

## Create the project

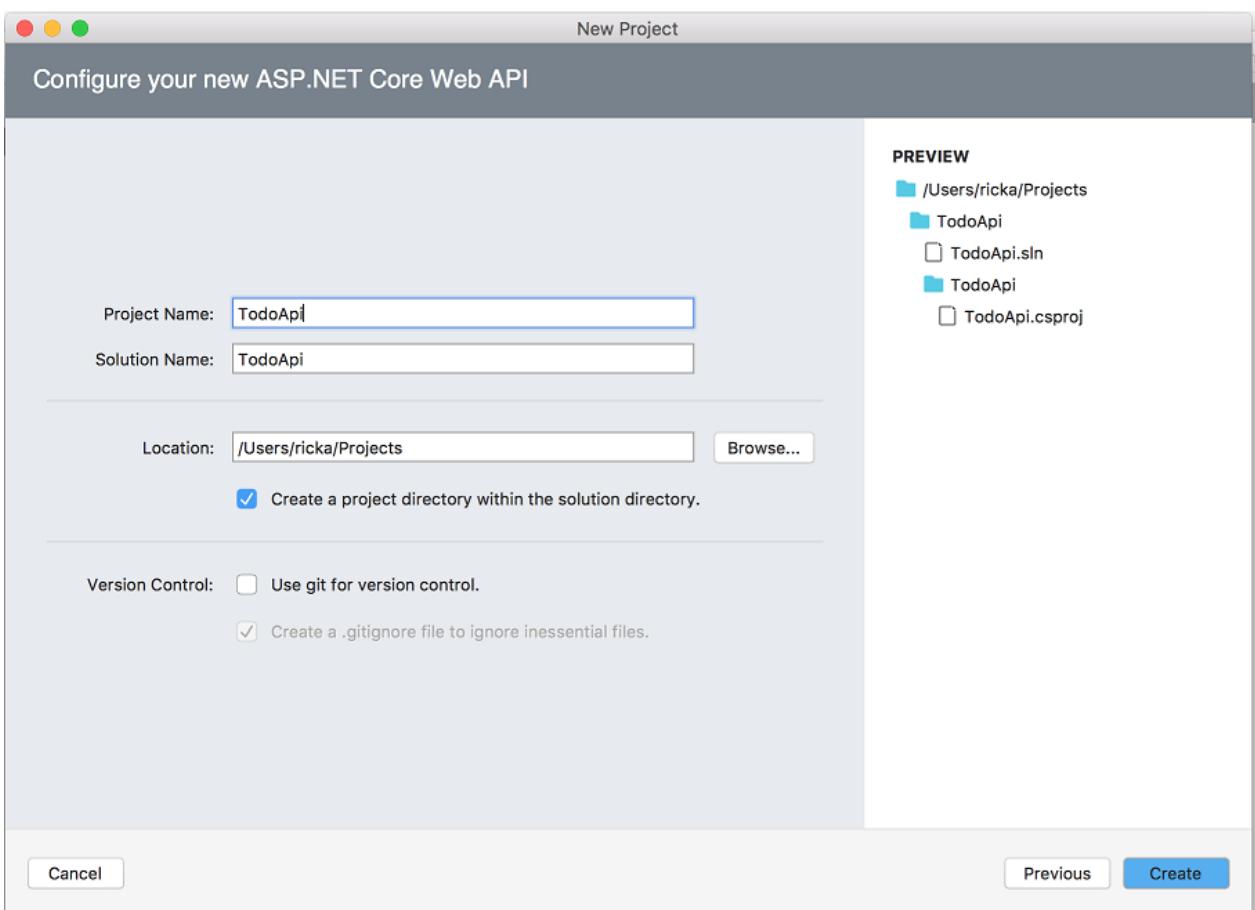

From Visual Studio, select **File > New Solution**.

Select **.NET Core App > ASP.NET Core Web API > Next**.

Enter `TodoApi` for the **Project Name**, and then click **Create**.

## Launch the app

In Visual Studio, select **Run > Start With Debugging** to launch the app. Visual Studio launches a browser and navigates to `http://localhost:5000`. You get an HTTP 404 (Not Found) error. Change the URL to `http://localhost:<port>/api/values`. The `ValuesController` data is displayed:

```
["value1","value2"]
```

## Add support for Entity Framework Core

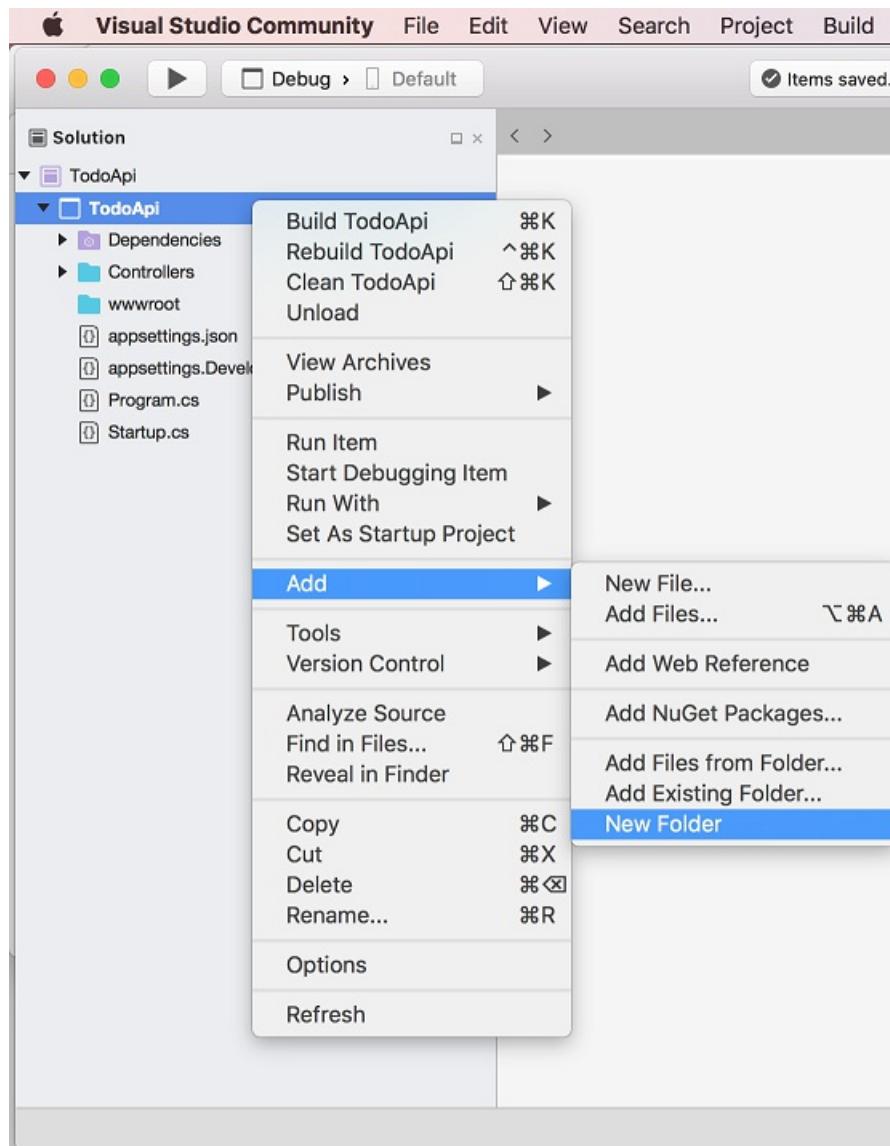

Install the [Entity Framework Core InMemory](#) database provider. This database provider allows Entity Framework Core to be used with an in-memory database.

- From the **Project** menu, select **Add NuGet Packages**.
  - Alternatively, you can right-click **Dependencies**, and then select **Add Packages**.
- Enter `EntityFrameworkCore.InMemory` in the search box.
- Select `Microsoft.EntityFrameworkCore.InMemory`, and then select **Add Package**.

## Add a model class

A model is an object representing the data in your app. In this case, the only model is a to-do item.

In Solution Explorer, right-click the project. Select **Add > New Folder**. Name the folder *Models*.

### NOTE

You can put model classes anywhere in your project, but the *Models* folder is used by convention.

Right-click the *Models* folder, and select **Add > New File > General > Empty Class**. Name the class *TodoItem*,

and then click **New**.

Replace the generated code with:

```
namespace TodoApi.Models
{
    public class TodoItem
    {
        public long Id { get; set; }
        public string Name { get; set; }
        public bool IsComplete { get; set; }
    }
}
```

The database generates the `Id` when a `TodoItem` is created.

### Create the database context

The *database context* is the main class that coordinates Entity Framework functionality for a given data model.

You create this class by deriving from the `Microsoft.EntityFrameworkCore.DbContext` class.

Add a `TodoContext` class to the *Models* folder.

```
using Microsoft.EntityFrameworkCore;

namespace TodoApi.Models
{
    public class TodoContext : DbContext
    {
        public TodoContext(DbContextOptions<TodoContext> options)
            : base(options)
        {

        }

        public DbSet<TodoItem> TodoItems { get; set; }
    }
}
```

## Register the database context

In this step, the database context is registered with the [dependency injection](#) container. Services (such as the DB context) that are registered with the dependency injection (DI) container are available to the controllers.

Register the DB context with the service container using the built-in support for [dependency injection](#). Replace the contents of the *Startup.cs* file with the following code:

```

using Microsoft.AspNetCore.Builder;
using Microsoft.AspNetCore.Mvc;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using TodoApi.Models;

namespace TodoApi
{
    public class Startup
    {
        public void ConfigureServices(IServiceCollection services)
        {
            services.AddDbContext<TodoContext>(opt =>
                opt.UseInMemoryDatabase("TodoList"));
            services.AddMvc()
                .SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
        }

        public void Configure(IApplicationBuilder app)
        {
            app.UseMvc();
        }
    }
}

```

```

using Microsoft.AspNetCore.Builder;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using TodoApi.Models;

namespace TodoApi
{
    public class Startup
    {
        public void ConfigureServices(IServiceCollection services)
        {
            services.AddDbContext<TodoContext>(opt =>
                opt.UseInMemoryDatabase("TodoList"));
            services.AddMvc();
        }

        public void Configure(IApplicationBuilder app)
        {
            app.UseMvc();
        }
    }
}

```

The preceding code:

- Removes the unused code.
- Specifies an in-memory database is injected into the service container.

## Add a controller

In Solution Explorer, in the *Controllers* folder, add the class `TodoController`.

Replace the generated code with the following:

```

using Microsoft.AspNetCore.Mvc;
using System.Collections.Generic;
using System.Linq;
using TodoApi.Models;

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

        public TodoController(TodoContext context)
        {
            _context = context;

            if (_context.TodoItems.Count() == 0)
            {
                _context.TodoItems.Add(new TodoItem { Name = "Item1" });
                _context.SaveChanges();
            }
        }
    }
}

```

The preceding code defines an API controller class without methods. In the next sections, methods are added to implement the API.

```

using Microsoft.AspNetCore.Mvc;
using System.Collections.Generic;
using System.Linq;
using TodoApi.Models;

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    [ApiController]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

        public TodoController(TodoContext context)
        {
            _context = context;

            if (_context.TodoItems.Count() == 0)
            {
                _context.TodoItems.Add(new TodoItem { Name = "Item1" });
                _context.SaveChanges();
            }
        }
    }
}

```

The preceding code defines an API controller class without methods. In the next sections, methods are added to implement the API. The class is annotated with an `[ApiController]` attribute to enable some convenient features. For information on features enabled by the attribute, see [Annotate class with ApiControllerAttribute](#).

The controller's constructor uses [Dependency Injection](#) to inject the database context (`TodoContext`) into the controller. The database context is used in each of the [CRUD](#) methods in the controller. The constructor adds an item to the in-memory database if one doesn't exist.

## Get to-do items

To get to-do items, add the following methods to the `TodoController` class:

```
[HttpGet]
public List<TodoItem> GetAll()
{
    return _context.TodoItems.ToList();
}

[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}
```

```
[HttpGet]
public ActionResult<List<TodoItem>> GetAll()
{
    return _context.TodoItems.ToList();
}

[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}
```

These methods implement the two GET methods:

- `GET /api/todo`
- `GET /api/todo/{id}`

Here's a sample HTTP response for the `GetAll` method:

```
[
{
    "id": 1,
    "name": "Item1",
    "isComplete": false
}]
```

Later in the tutorial, I'll show how the HTTP response can be viewed with [Postman](#) or [curl](#).

### Routing and URL paths

The `[HttpGet]` attribute denotes a method that responds to an HTTP GET request. The URL path for each method is constructed as follows:

- Take the template string in the controller's `Route` attribute:

```

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

```

```

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    [ApiController]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

```

- Replace `[controller]` with the name of the controller, which is the controller class name minus the "Controller" suffix. For this sample, the controller class name is **TodoController** and the root name is "todo". ASP.NET Core [routing](#) is case insensitive.
- If the `[HttpGet]` attribute has a route template (such as `[HttpGet("/products")]`), append that to the path. This sample doesn't use a template. For more information, see [Attribute routing with Http\[Verb\] attributes](#).

In the following  `GetById` method, `"{id}"` is a placeholder variable for the unique identifier of the to-do item. When  `GetById` is invoked, it assigns the value of `"{id}"` in the URL to the method's `id` parameter.

```

[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}

```

```

[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}

```

`Name = "GetTodo"` creates a named route. Named routes:

- Enable the app to create an HTTP link using the route name.
- Are explained later in the tutorial.

## Return values

The  `GetAll` method returns a collection of  `TodoItem` objects. MVC automatically serializes the object to [JSON](#) and writes the JSON into the body of the response message. The response code for this method is 200, assuming there are no unhandled exceptions. Unhandled exceptions are translated into 5xx errors.

In contrast, the  `GetById` method returns the more general [IActionResult type](#), which represents a wide range of

return types.  `GetById` has two different return types:

- If no item matches the requested ID, the method returns a 404 error. Returning `NotFound` returns an HTTP 404 response.
- Otherwise, the method returns 200 with a JSON response body. Returning `Ok` results in an HTTP 200 response.

In contrast, the  `GetById` method returns the `ActionResult<T>` type, which represents a wide range of return types.  `GetById` has two different return types:

- If no item matches the requested ID, the method returns a 404 error. Returning `NotFound` returns an HTTP 404 response.
- Otherwise, the method returns 200 with a JSON response body. Returning `item` results in an HTTP 200 response.

## Launch the app

In Visual Studio, select **Run > Start With Debugging** to launch the app. Visual Studio launches a browser and navigates to `http://localhost:<port>`, where `<port>` is a randomly chosen port number. You get an HTTP 404 (Not Found) error. Change the URL to `http://localhost:<port>/api/values`. The `ValuesController` data is displayed:

```
["value1","value2"]
```

Navigate to the  `Todo` controller at `http://localhost:<port>/api/todo`. The following JSON is returned:

```
[{"key":1,"name":"Item1","isComplete":false}]
```

## Implement the other CRUD operations

We'll add `Create`, `Update`, and `Delete` methods to the controller. These methods are variations on a theme, so I'll just show the code and highlight the main differences. Build the project after adding or changing code.

### Create

```
[HttpPost]
public IActionResult Create([FromBody] TodoItem item)
{
    if (item == null)
    {
        return BadRequest();
    }

    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}
```

The preceding method responds to an HTTP POST, as indicated by the `[HttpPost]` attribute. The `[FromBody]` attribute tells MVC to get the value of the to-do item from the body of the HTTP request.

```
[HttpPost]
public IActionResult Create(TodoItem item)
{
    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}
```

The preceding method responds to an HTTP POST, as indicated by the `[HttpPost]` attribute. MVC gets the value of the to-do item from the body of the HTTP request.

The `CreatedAtRoute` method returns a 201 response. It's the standard response for an HTTP POST method that creates a new resource on the server. `CreatedAtRoute` also adds a Location header to the response. The Location header specifies the URI of the newly created to-do item. See [10.2.2 201 Created](#).

### Use Postman to send a Create request

- Start the app (**Run > Start With Debugging**).
- Open Postman.

- Update the port number in the localhost URL.
- Set the HTTP method to *POST*.
- Click the **Body** tab.
- Select the **raw** radio button.
- Set the type to *JSON (application/json)*.
- Enter a request body with a to-do item resembling the following JSON:

```
{  
    "name": "walk dog",  
    "isComplete": true  
}
```

- Click the **Send** button.

#### TIP

If no response displays after clicking **Send**, disable the **SSL certification verification** option. This is found under **File > Settings**. Click the **Send** button again after disabling the setting.

Click the **Headers** tab in the **Response** pane and copy the **Location** header value:

The screenshot shows the Postman application interface. A POST request is being made to `https://localhost:44375/api/todo`. The request body is set to raw JSON, containing the object defined at the top of the page. The 'Headers' tab is selected in the response pane, which displays several headers, including the 'Location' header which is highlighted with a red box. The status of the request is 201 Created, and it took 148 ms.

You can use the Location header URI to access the resource you created. The `Create` method returns `CreatedAtRoute`. The first parameter passed to `CreatedAtRoute` represents the named route to use for generating the URL. Recall that the  `GetById` method created the `"GetTodo"` named route:

```
[HttpGet("{id}", Name = "GetTodo")]
```

## Update

```
[HttpPut("{id}")]
public IActionResult Update(long id, [FromBody] TodoItem item)
{
    if (item == null || item.Id != id)
    {
        return BadRequest();
    }

    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    todo.IsComplete = item.IsComplete;
    todo.Name = item.Name;

    _context.TodoItems.Update(todo);
    _context.SaveChanges();
    return NoContent();
}
```

```
[HttpPut("{id}")]
public IActionResult Update(long id, TodoItem item)
{
    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    todo.IsComplete = item.IsComplete;
    todo.Name = item.Name;

    _context.TodoItems.Update(todo);
    _context.SaveChanges();
    return NoContent();
}
```

`Update` is similar to `Create`, but uses HTTP PUT. The response is [204 \(No Content\)](#). According to the HTTP spec, a PUT request requires the client to send the entire updated entity, not just the deltas. To support partial updates, use HTTP PATCH.

```
{
    "key": 1,
    "name": "walk dog",
    "isComplete": true
}
```

The screenshot shows the Postman application interface. A red box highlights the 'PUT' method in the top left. The URL 'https://localhost:44375/api/todo/1' is entered in the main input field. To the right are buttons for 'Params' and a large blue 'Send' button. Below the URL, tabs for 'Authorization', 'Headers (3)', 'Body (●)', 'Pre-request Script', and 'Tests' are visible, with 'Body' being the active tab. A red box highlights the 'Body' tab. Under 'Body', there are four options: 'form-data', 'x-www-form-urlencoded', 'raw', and 'binary'. 'raw' is selected and highlighted with a red box. To its right is a dropdown set to 'JSON (application/json)'. The 'Body' content area contains the following JSON:

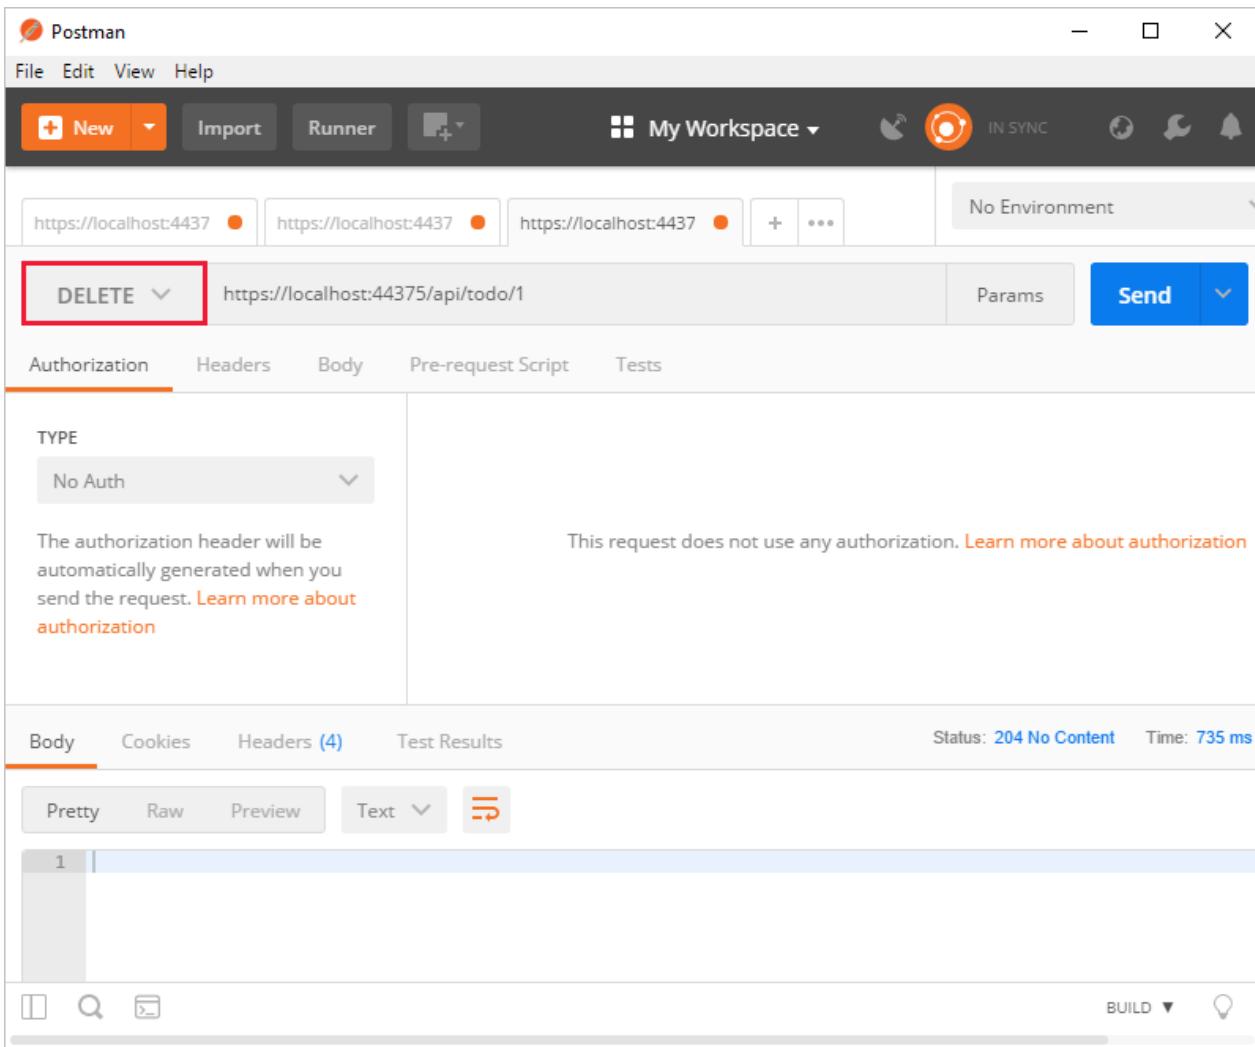

```
1 {  
2   "name": "walk cat",  
3   "isComplete": true  
4 }
```

## Delete

```
[HttpDelete("{id}")]
public IActionResult Delete(long id)
{
    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    _context.TodoItems.Remove(todo);
    _context.SaveChanges();
    return NoContent();
}
```

The response is 204 (No Content).

## Call the Web API with jQuery

In this section, an HTML page is added that uses jQuery to call the Web API. jQuery initiates the request and updates the page with the details from the API's response.

Configure the project to serve static files and to enable default file mapping. This is accomplished by invoking the [UseStaticFiles](#) and [UseDefaultFiles](#) extension methods in *Startup.Configure*. For more information, see [Static files](#).

```
public void Configure(IApplicationBuilder app)
{
    app.UseDefaultFiles();
    app.UseStaticFiles();
    app.UseMvc();
}
```

Add an HTML file, named *index.html*, to the project's *wwwroot* directory. Replace its contents with the following markup:

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="UTF-8">
    <title>To-do CRUD</title>
    <style>
        input[type='submit'], button, [aria-label] {
            cursor: pointer;
        }
    </style>

```

```

    #spoiler {
        display: none;
    }

    table {
        font-family: Arial, sans-serif;
        border: 1px solid;
        border-collapse: collapse;
    }

    th {
        background-color: #0066CC;
        color: white;
    }

    td {
        border: 1px solid;
        padding: 5px;
    }

```

</style>

</head>

<body>

<h1>To-do CRUD</h1>

<h3>Add</h3>

<form action="javascript:void(0);" method="POST" onsubmit="addItem()">

<input type="text" id="add-name" placeholder="New to-do">

<input type="submit" value="Add">

</form>

<div id="spoiler">

<h3>Edit</h3>

<form class="my-form">

<input type="hidden" id="edit-id">

<input type="checkbox" id="edit-isComplete">

<input type="text" id="edit-name">

<input type="submit" value="Edit">

<a onclick="closeInput()" aria-label="Close" href="#">Close</a>

</form>

</div>

<p id="counter"></p>

<table>

<tr>

<th>Is Complete</th>

<th>Name</th>

<th></th>

<th></th>

</tr>

<tbody id="todos"></tbody>

</table>

<script src="https://code.jquery.com/jquery-3.3.1.min.js"
 integrity="sha256-FgpCb/KJQlLNfOu91ta32o/NMZxltwRo8QtmkMRdAu8="
 crossorigin="anonymous"></script>

<script src="site.js"></script>

</body>

</html>

Add a JavaScript file, named *site.js*, to the project's *wwwroot* directory. Replace its contents with the following code:

```

const uri = 'api/todo';
let todos = null;
function getCount(data) {
    const el = $('#counter');

```

```

let name = 'to-do';
if (data) {
    if (data > 1) {
        name = 'to-dos';
    }
    el.text(data + ' ' + name);
} else {
    el.html('No ' + name);
}

$(document).ready(function () {
    getData();
});

function getData() {
    $.ajax({
        type: 'GET',
        url: uri,
        success: function (data) {
            $('#todos').empty();
            getCount(data.length);
            $.each(data, function (key, item) {
                const checked = item.isComplete ? 'checked' : '';
                $(`<tr><td><input disabled="true" type="checkbox" ${checked}></td>' +
                    '<td>' + item.name + '</td>' +
                    '<td><button onclick="editItem(' + item.id + ')">Edit</button></td>' +
                    '<td><button onclick="deleteItem(' + item.id + ')">Delete</button></td>' +
                    '</tr>').appendTo($('#todos'));
            });
            todos = data;
        }
    });
}

function addItem() {
    const item = {
        'name': $('#add-name').val(),
        'isComplete': false
    };

    $.ajax({
        type: 'POST',
        accepts: 'application/json',
        url: uri,
        contentType: 'application/json',
        data: JSON.stringify(item),
        error: function (jqXHR, textStatus, errorThrown) {
            alert('here');
        },
        success: function (result) {
            getData();
            $('#add-name').val('');
        }
    });
}

function deleteItem(id) {
    $.ajax({
        url: uri + '/' + id,
        type: 'DELETE',
        success: function (result) {
            getData();
        }
    });
}

```

```

function editItem(id) {
    $.each(todos, function (key, item) {
        if (item.id === id) {
            $('#edit-name').val(item.name);
            $('#edit-id').val(item.id);
            $('#edit-isComplete').val(item.isComplete);
        }
    });
    $('#spoiler').css({ 'display': 'block' });
}

$('.my-form').on('submit', function () {
    const item = {
        'name': $('#edit-name').val(),
        'isComplete': $('#edit-isComplete').is(':checked'),
        'id': $('#edit-id').val()
    };

    $.ajax({
        url: uri + '/' + $('#edit-id').val(),
        type: 'PUT',
        accepts: 'application/json',
        contentType: 'application/json',
        data: JSON.stringify(item),
        success: function (result) {
            getData();
        }
    });
    closeInput();
    return false;
});

function closeInput() {
    $('#spoiler').css({ 'display': 'none' });
}

```

A change to the ASP.NET Core project's launch settings may be required to test the HTML page locally. Open `launchSettings.json` in the *Properties* directory of the project. Remove the `launchUrl` property to force the app to open at `index.html`—the project's default file.

There are several ways to get jQuery. In the preceding snippet, the library is loaded from a CDN. This sample is a complete CRUD example of calling the API with jQuery. There are additional features in this sample to make the experience richer. Below are explanations around the calls to the API.

### Get a list of to-do items

To get a list of to-do items, send an HTTP GET request to `/api/todo`.

The jQuery `ajax` function sends an AJAX request to the API, which returns JSON representing an object or array. This function can handle all forms of HTTP interaction, sending an HTTP request to the specified `url`. `GET` is used as the `type`. The `success` callback function is invoked if the request succeeds. In the callback, the DOM is updated with the to-do information.

```

$(document).ready(function () {
    getData();
});

function getData() {
    $.ajax({
        type: 'GET',
        url: uri,
        success: function (data) {
            $('#todos').empty();
            getCount(data.length);
            $.each(data, function (key, item) {
                const checked = item.isComplete ? 'checked' : '';
                $('<tr><td><input disabled="true" type="checkbox" ' + checked + '></td>' +
                    '<td>' + item.name + '</td>' +
                    '<td><button onclick="editItem(' + item.id + ')>Edit</button></td>' +
                    '<td><button onclick="deleteItem(' + item.id + ')>Delete</button></td>' +
                    '</tr>').appendTo($('#todos'));
            });
            todos = data;
        }
    });
}

```

## Add a to-do item

To add a to-do item, send an HTTP POST request to `/api/todo/`. The request body should contain a to-do object. The `ajax` function is using `POST` to call the API. For `POST` and `PUT` requests, the request body represents the data sent to the API. The API is expecting a JSON request body. The `accepts` and `contentType` options are set to `application/json` to classify the media type being received and sent, respectively. The data is converted to a JSON object using `JSON.stringify`. When the API returns a successful status code, the `getData` function is invoked to update the HTML table.

```

function addItem() {
    const item = {
        'name': $('#add-name').val(),
        'isComplete': false
    };

    $.ajax({
        type: 'POST',
        accepts: 'application/json',
        url: uri,
        contentType: 'application/json',
        data: JSON.stringify(item),
        error: function (jqXHR, textStatus, errorThrown) {
            alert('here');
        },
        success: function (result) {
            getData();
            $('#add-name').val('');
        }
    });
}

```

## Update a to-do item

Updating a to-do item is very similar to adding one, since both rely on a request body. The only real difference between the two in this case is that the `url` changes to add the unique identifier of the item, and the `type` is `PUT`.

```
$.ajax({
    url: uri + '/' + $('#edit-id').val(),
    type: 'PUT',
    accepts: 'application/json',
    contentType: 'application/json',
    data: JSON.stringify(item),
    success: function (result) {
        getData();
    }
});
```

## Delete a to-do item

Deleting a to-do item is accomplished by setting the `type` on the AJAX call to `DELETE` and specifying the item's unique identifier in the URL.

```
$.ajax({
    url: uri + '/' + id,
    type: 'DELETE',
    success: function (result) {
        getData();
    }
});
```

## Next steps

- For information on using a persistent database, see:
  - [Create a Razor Pages web app with ASP.NET Core](#)
  - [Work with data in ASP.NET Core](#)

# Create a Web API with ASP.NET Core and Visual Studio Code

6/21/2018 • 15 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Mike Wasson](#)

In this tutorial, build a web API for managing a list of "to-do" items. A UI isn't constructed.

There are three versions of this tutorial:

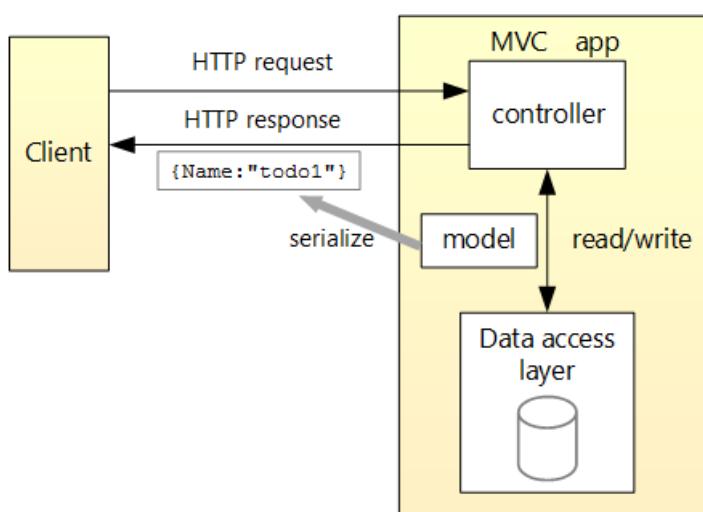

- macOS, Linux, Windows: Web API with Visual Studio Code (This tutorial)
- macOS: [Web API with Visual Studio for Mac](#)
- Windows: [Web API with Visual Studio for Windows](#)

## Overview

This tutorial creates the following API:

API	DESCRIPTION	REQUEST BODY	RESPONSE BODY
GET /api/todo	Get all to-do items	None	Array of to-do items
GET /api/todo/{id}	Get an item by ID	None	To-do item
POST /api/todo	Add a new item	To-do item	To-do item
PUT /api/todo/{id}	Update an existing item	To-do item	None
DELETE /api/todo/{id}	Delete an item	None	None

The following diagram shows the basic design of the app.

- The client is whatever consumes the web API (mobile app, browser, etc.). This tutorial doesn't create a client. [Postman](#) or [curl](#) is used as the client to test the app.
- A *model* is an object that represents the data in the app. In this case, the only model is a to-do item. Models are represented as C# classes, also known as **Plain Old CLR Object** (POCOs).

- A *controller* is an object that handles HTTP requests and creates the HTTP response. This app has a single controller.
- To keep the tutorial simple, the app doesn't use a persistent database. The sample app stores to-do items in an in-memory database.

## Prerequisites

Install the following:

- .NET Core SDK 2.0 or later
- Visual Studio Code
- C# for Visual Studio Code
- .NET Core 2.1 SDK or later
- Visual Studio Code
- C# for Visual Studio Code

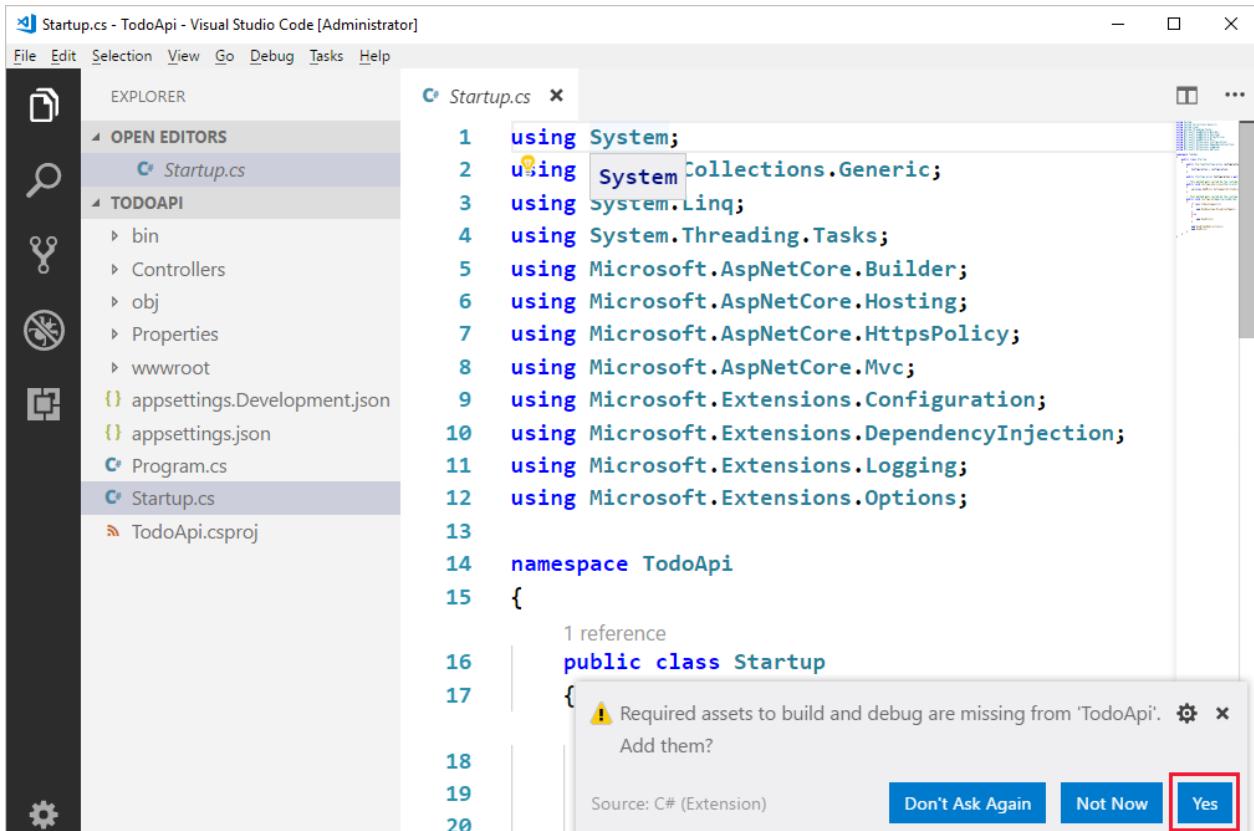

## Create the project

From a console, run the following commands:

```
dotnet new webapi -o TodoApi
code TodoApi
```

The *TodoApi* folder opens in Visual Studio Code (VS Code). Select the *Startup.cs* file.

- Select **Yes** to the **Warn** message "Required assets to build and debug are missing from 'TodoApi'. Add them?"
- Select **Restore** to the **Info** message "There are unresolved dependencies".

Press **Debug** (F5) to build and run the program. In a browser, navigate to <http://localhost:5000/api/values>. The

following output is displayed:

```
[ "value1", "value2" ]
```

See [Visual Studio Code help](#) for tips on using VS Code.

## Add support for Entity Framework Core

Creating a new project in ASP.NET Core 2.0 adds the [Microsoft.AspNetCore.All](#) package reference to the *TodoApi.csproj* file:

```
<ItemGroup>
  <PackageReference Include="Microsoft.AspNetCore.All" Version="2.0.3" />
</ItemGroup>
```

Creating a new project in ASP.NET Core 2.1 or later adds the [Microsoft.AspNetCore.App](#) package reference to the *TodoApi.csproj* file:

```
<ItemGroup>
  <PackageReference Include="Microsoft.AspNetCore.App" Version="2.1.1" />
</ItemGroup>
```

There's no need to install the [Entity Framework Core InMemory](#) database provider separately. This database provider allows Entity Framework Core to be used with an in-memory database.

## Add a model class

A model is an object representing the data in your app. In this case, the only model is a to-do item.

Add a folder named *Models*. You can put model classes anywhere in your project, but the *Models* folder is used by convention.

Add a `TodoItem` class with the following code:

```
namespace TodoApi.Models
{
    public class TodoItem
    {
        public long Id { get; set; }
        public string Name { get; set; }
        public bool IsComplete { get; set; }
    }
}
```

The database generates the `Id` when a `TodoItem` is created.

## Create the database context

The *database context* is the main class that coordinates Entity Framework functionality for a given data model. You create this class by deriving from the [Microsoft.EntityFrameworkCore.DbContext](#) class.

Add a `TodoContext` class in the *Models* folder:

```
using Microsoft.EntityFrameworkCore;

namespace TodoApi.Models
{
    public class TodoContext : DbContext
    {
        public TodoContext(DbContextOptions<TodoContext> options)
            : base(options)
        {
        }

        public DbSet<TodoItem> TodoItems { get; set; }
    }
}
```

## Register the database context

In this step, the database context is registered with the [dependency injection](#) container. Services (such as the DB context) that are registered with the dependency injection (DI) container are available to the controllers.

Register the DB context with the service container using the built-in support for [dependency injection](#). Replace the contents of the *Startup.cs* file with the following code:

```
using Microsoft.AspNetCore.Builder;
using Microsoft.AspNetCore.Mvc;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using TodoApi.Models;

namespace TodoApi
{
    public class Startup
    {
        public void ConfigureServices(IServiceCollection services)
        {
            services.AddDbContext<TodoContext>(opt =>
                opt.UseInMemoryDatabase("TodoList"));
            services.AddMvc()
                .SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
        }

        public void Configure(IApplicationBuilder app)
        {
            app.UseMvc();
        }
    }
}
```

```

using Microsoft.AspNetCore.Builder;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.DependencyInjection;
using TodoApi.Models;

namespace TodoApi
{
    public class Startup
    {
        public void ConfigureServices(IServiceCollection services)
        {
            services.AddDbContext<TodoContext>(opt =>
                opt.UseInMemoryDatabase("TodoList"));
            services.AddMvc();
        }

        public void Configure(IApplicationBuilder app)
        {
            app.UseMvc();
        }
    }
}

```

The preceding code:

- Removes the unused code.
- Specifies an in-memory database is injected into the service container.

## Add a controller

In the *Controllers* folder, create a class named `| TodoController |`. Replace its contents with the following code:

```

using Microsoft.AspNetCore.Mvc;
using System.Collections.Generic;
using System.Linq;
using TodoApi.Models;

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

        public TodoController(TodoContext context)
        {
            _context = context;

            if (_context.TodoItems.Count() == 0)
            {
                _context.TodoItems.Add(new TodoItem { Name = "Item1" });
                _context.SaveChanges();
            }
        }
    }
}

```

The preceding code defines an API controller class without methods. In the next sections, methods are added to implement the API.

```

using Microsoft.AspNetCore.Mvc;
using System.Collections.Generic;
using System.Linq;
using TodoApi.Models;

namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    [ApiController]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;

        public TodoController(TodoContext context)
        {
            _context = context;

            if (_context.TodoItems.Count() == 0)
            {
                _context.TodoItems.Add(new TodoItem { Name = "Item1" });
                _context.SaveChanges();
            }
        }
    }
}

```

The preceding code defines an API controller class without methods. In the next sections, methods are added to implement the API. The class is annotated with an `[ApiController]` attribute to enable some convenient features. For information on features enabled by the attribute, see [Annotate class with ApiControllerAttribute](#).

The controller's constructor uses [Dependency Injection](#) to inject the database context (`TodoContext`) into the controller. The database context is used in each of the [CRUD](#) methods in the controller. The constructor adds an item to the in-memory database if one doesn't exist.

## Get to-do items

To get to-do items, add the following methods to the `TodoController` class:

```

[HttpGet]
public List<TodoItem> GetAll()
{
    return _context.TodoItems.ToList();
}

[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}

```

```
[HttpGet]
public ActionResult<List<TodoItem>> GetAll()
{
    return _context.TodoItems.ToList();
}

[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}
```

These methods implement the two GET methods:

- `GET /api/todo`
- `GET /api/todo/{id}`

Here's a sample HTTP response for the `GetAll` method:

```
[
{
    "id": 1,
    "name": "Item1",
    "isComplete": false
}]
```

Later in the tutorial, I'll show how the HTTP response can be viewed with [Postman](#) or [curl](#).

## Routing and URL paths

The `[HttpGet]` attribute denotes a method that responds to an HTTP GET request. The URL path for each method is constructed as follows:

- Take the template string in the controller's `Route` attribute:

```
namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;
```

```
namespace TodoApi.Controllers
{
    [Route("api/[controller]")]
    [ApiController]
    public class TodoController : ControllerBase
    {
        private readonly TodoContext _context;
```

- Replace `[controller]` with the name of the controller, which is the controller class name minus the "Controller" suffix. For this sample, the controller class name is **TodoController** and the root name is "todo". ASP.NET Core [routing](#) is case insensitive.

- If the `[HttpGet]` attribute has a route template (such as `[HttpGet("/products")]`), append that to the path. This sample doesn't use a template. For more information, see [Attribute routing with Http\[Verb\] attributes](#).

In the following  `GetById` method, `"{id}"` is a placeholder variable for the unique identifier of the to-do item. When  `GetById` is invoked, it assigns the value of `"{id}"` in the URL to the method's `id` parameter.

```
[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}
```

```
[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}
```

`Name = "GetTodo"` creates a named route. Named routes:

- Enable the app to create an HTTP link using the route name.
- Are explained later in the tutorial.

## Return values

The  `GetAll` method returns a collection of  `TodoItem` objects. MVC automatically serializes the object to  `JSON` and writes the JSON into the body of the response message. The response code for this method is 200, assuming there are no unhandled exceptions. Unhandled exceptions are translated into 5xx errors.

In contrast, the  `GetById` method returns the more general `IActionResult type`, which represents a wide range of return types.  `GetById` has two different return types:

- If no item matches the requested ID, the method returns a 404 error. Returning `NotFound` returns an HTTP 404 response.
- Otherwise, the method returns 200 with a JSON response body. Returning `Ok` results in an HTTP 200 response.

In contrast, the  `GetById` method returns the  `ActionResult<T> type`, which represents a wide range of return types.  `GetById` has two different return types:

- If no item matches the requested ID, the method returns a 404 error. Returning `NotFound` returns an HTTP 404 response.
- Otherwise, the method returns 200 with a JSON response body. Returning  `item` results in an HTTP 200 response.

## Launch the app

In VS Code, press F5 to launch the app. Navigate to `http://localhost:5000/api/todo` (the  `Todo` controller we created).

## Call the Web API with jQuery

In this section, an HTML page is added that uses jQuery to call the Web API. jQuery initiates the request and updates the page with the details from the API's response.

Configure the project to serve static files and to enable default file mapping. This is accomplished by invoking the [UseStaticFiles](#) and [UseDefaultFiles](#) extension methods in *Startup.Configure*. For more information, see [Static files](#).

```
public void Configure(IApplicationBuilder app)
{
    app.UseDefaultFiles();
    app.UseStaticFiles();
    app.UseMvc();
}
```

Add an HTML file, named *index.html*, to the project's *wwwroot* directory. Replace its contents with the following markup:

```
<!DOCTYPE html>
<html>
<head>
    <meta charset="UTF-8">
    <title>To-do CRUD</title>
    <style>
        input[type='submit'], button, [aria-label] {
            cursor: pointer;
        }

        #spoiler {
            display: none;
        }

        table {
            font-family: Arial, sans-serif;
            border: 1px solid;
            border-collapse: collapse;
        }

        th {
            background-color: #0066CC;
            color: white;
        }

        td {
            border: 1px solid;
            padding: 5px;
        }
    </style>
</head>
<body>
    <h1>To-do CRUD</h1>
    <h3>Add</h3>
    <form action="javascript:void(0);" method="POST" onsubmit="addItem()">
        <input type="text" id="add-name" placeholder="New to-do">
        <input type="submit" value="Add">
    </form>

    <div id="spoiler">
        <h3>Edit</h3>
        <form class="my-form">
            <input type="hidden" id="edit-id">
            <input type="checkbox" id="edit-isComplete">
            <input type="text" id="edit-name">
        </form>
    </div>
</body>
```

```

        <input type="submit" value="Edit">
        <a onclick="closeInput()" aria-label="Close">✖</a>
    </form>
</div>

<p id="counter"></p>

<table>
    <tr>
        <th>Is Complete</th>
        <th>Name</th>
        <th></th>
        <th></th>
    </tr>
    <tbody id="todos"></tbody>
</table>

<script src="https://code.jquery.com/jquery-3.3.1.min.js"
    integrity="sha256-FgpCb/KJQlLNfOu91ta32o/NMZxltwRo8QtmkMRdAu8="
    crossorigin="anonymous"></script>
<script src="site.js"></script>
</body>
</html>

```

Add a JavaScript file, named *site.js*, to the project's *wwwroot* directory. Replace its contents with the following code:

```

const uri = 'api/todo';
let todos = null;
function getCount(data) {
    const el = $('#counter');
    let name = 'to-do';
    if (data) {
        if (data > 1) {
            name = 'to-dos';
        }
        el.text(data + ' ' + name);
    } else {
        el.html('No ' + name);
    }
}

$(document).ready(function () {
    getData();
});

function getData() {
    $.ajax({
        type: 'GET',
        url: uri,
        success: function (data) {
            $('#todos').empty();
            getCount(data.length);
            $.each(data, function (key, item) {
                const checked = item.isComplete ? 'checked' : '';
                $('<tr><td><input disabled="true" type="checkbox" ' + checked + '></td>' +
                    '<td>' + item.name + '</td>' +
                    '<td><button onclick="editItem(' + item.id + ')">Edit</button></td>' +
                    '<td><button onclick="deleteItem(' + item.id + ')">Delete</button></td>' +
                    '</tr>').appendTo($('#todos'));
            });
            todos = data;
        }
    });
}

```

```

function addItem() {
  const item = {
    'name': $('#add-name').val(),
    'isComplete': false
  };

  $.ajax({
    type: 'POST',
    accepts: 'application/json',
    url: uri,
    contentType: 'application/json',
    data: JSON.stringify(item),
    error: function (jqXHR, textStatus, errorThrown) {
      alert('here');
    },
    success: function (result) {
      getData();
      $('#add-name').val('');
    }
  });
}

function deleteItem(id) {
  $.ajax({
    url: uri + '/' + id,
    type: 'DELETE',
    success: function (result) {
      getData();
    }
  });
}

function editItem(id) {
  $.each(todos, function (key, item) {
    if (item.id === id) {
      $('#edit-name').val(item.name);
      $('#edit-id').val(item.id);
      $('#edit-isComplete').val(item.isComplete);
    }
  });
  $('#spoiler').css({ 'display': 'block' });
}

$('.my-form').on('submit', function () {
  const item = {
    'name': $('#edit-name').val(),
    'isComplete': $('#edit-isComplete').is(':checked'),
    'id': $('#edit-id').val()
  };

  $.ajax({
    url: uri + '/' + $('#edit-id').val(),
    type: 'PUT',
    accepts: 'application/json',
    contentType: 'application/json',
    data: JSON.stringify(item),
    success: function (result) {
      getData();
    }
  });

  closeInput();
  return false;
});

function closeInput() {
  $('#spoiler').css({ 'display': 'none' });
}

```

A change to the ASP.NET Core project's launch settings may be required to test the HTML page locally. Open `launchSettings.json` in the `Properties` directory of the project. Remove the `launchUrl` property to force the app to open at `index.html`—the project's default file.

There are several ways to get jQuery. In the preceding snippet, the library is loaded from a CDN. This sample is a complete CRUD example of calling the API with jQuery. There are additional features in this sample to make the experience richer. Below are explanations around the calls to the API.

### Get a list of to-do items

To get a list of to-do items, send an HTTP GET request to `/api/todo`.

The jQuery `ajax` function sends an AJAX request to the API, which returns JSON representing an object or array. This function can handle all forms of HTTP interaction, sending an HTTP request to the specified `url`. `GET` is used as the `type`. The `success` callback function is invoked if the request succeeds. In the callback, the DOM is updated with the to-do information.

```
$(document).ready(function () {
    getData();
});

function getData() {
    $.ajax({
        type: 'GET',
        url: uri,
        success: function (data) {
            $('#todos').empty();
            getCount(data.length);
            $.each(data, function (key, item) {
                const checked = item.isComplete ? 'checked' : '';

                $('<tr><td><input disabled="true" type="checkbox" ' + checked + '></td>' +
                    '<td>' + item.name + '</td>' +
                    '<td><button onclick="editItem(' + item.id + ')">Edit</button></td>' +
                    '<td><button onclick="deleteItem(' + item.id + ')">Delete</button></td>' +
                    '</tr>').appendTo($('#todos'));
            });
            todos = data;
        }
    });
}
```

### Add a to-do item

To add a to-do item, send an HTTP POST request to `/api/todo/`. The request body should contain a to-do object. The `ajax` function is using `POST` to call the API. For `POST` and `PUT` requests, the request body represents the data sent to the API. The API is expecting a JSON request body. The `accepts` and `contentType` options are set to `application/json` to classify the media type being received and sent, respectively. The data is converted to a JSON object using `JSON.stringify`. When the API returns a successful status code, the `getData` function is invoked to update the HTML table.

```

function addItem() {
  const item = {
    'name': $('#add-name').val(),
    'isComplete': false
  };

  $.ajax({
    type: 'POST',
    accepts: 'application/json',
    url: uri,
    contentType: 'application/json',
    data: JSON.stringify(item),
    error: function (jqXHR, textStatus, errorThrown) {
      alert('here');
    },
    success: function (result) {
      getData();
      $('#add-name').val('');
    }
  });
}

```

## Update a to-do item

Updating a to-do item is very similar to adding one, since both rely on a request body. The only real difference between the two in this case is that the `url` changes to add the unique identifier of the item, and the `type` is `PUT`.

```

$.ajax({
  url: uri + '/' + $('#edit-id').val(),
  type: 'PUT',
  accepts: 'application/json',
  contentType: 'application/json',
  data: JSON.stringify(item),
  success: function (result) {
    getData();
  }
});

```

## Delete a to-do item

Deleting a to-do item is accomplished by setting the `type` on the AJAX call to `DELETE` and specifying the item's unique identifier in the URL.

```

$.ajax({
  url: uri + '/' + id,
  type: 'DELETE',
  success: function (result) {
    getData();
  }
});

```

# Implement the other CRUD operations

In the following sections, `Create`, `Update`, and `Delete` methods are added to the controller.

## Create

Add the following `Create` method:

```
[HttpPost]
public IActionResult Create([FromBody] TodoItem item)
{
    if (item == null)
    {
        return BadRequest();
    }

    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}
```

The preceding code is an HTTP POST method, as indicated by the `[HttpPost]` attribute. The `[FromBody]` attribute tells MVC to get the value of the to-do item from the body of the HTTP request.

```
[HttpPost]
public IActionResult Create(TodoItem item)
{
    _context.TodoItems.Add(item);
    _context.SaveChanges();

    return CreatedAtRoute("GetTodo", new { id = item.Id }, item);
}
```

The preceding code is an HTTP POST method, as indicated by the `[HttpPost]` attribute. MVC gets the value of the to-do item from the body of the HTTP request.

The `CreatedAtRoute` method:

- Returns a 201 response. HTTP 201 is the standard response for an HTTP POST method that creates a new resource on the server.
- Adds a Location header to the response. The Location header specifies the URI of the newly created to-do item. See [10.2.2 201 Created](#).
- Uses the "GetTodo" named route to create the URL. The "GetTodo" named route is defined in  `GetById`:

```
[HttpGet("{id}", Name = "GetTodo")]
public IActionResult GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return Ok(item);
}
```

```
[HttpGet("{id}", Name = "GetTodo")]
public ActionResult<TodoItem> GetById(long id)
{
    var item = _context.TodoItems.Find(id);
    if (item == null)
    {
        return NotFound();
    }
    return item;
}
```

## Use Postman to send a Create request

- Start the app.
- Open Postman.

The screenshot shows the Postman application window. At the top, the URL is set to `https://localhost:44375/api/todo`. The **Body** tab is selected, and the **raw** radio button is chosen. The JSON input field contains the following code:

```
1 {  
2   "name": "walk dog",  
3   "isComplete": true  
4 }
```

The response pane shows the result of the POST request:

```
1 {  
2   "id": 6,  
3   "name": "walk dog",  
4   "isComplete": true  
5 }
```

- Update the port number in the localhost URL.
- Set the HTTP method to *POST*.
- Click the **Body** tab.
- Select the **raw** radio button.
- Set the type to *JSON (application/json)*.
- Enter a request body with a to-do item resembling the following JSON:

```
{  
  "name": "walk dog",  
  "isComplete": true  
}
```

- Click the **Send** button.

### TIP

If no response displays after clicking **Send**, disable the **SSL certification verification** option. This is found under **File > Settings**. Click the **Send** button again after disabling the setting.

Click the **Headers** tab in the **Response** pane and copy the **Location** header value:

The screenshot shows the Postman application interface. At the top, there's a navigation bar with File, Edit, View, Help, and workspace-related buttons like New, Import, Runner, and My Workspace (IN SYNC). Below the bar, the URL is set to https://localhost:4437 and the method is POST. The target endpoint is https://localhost:44375/api/todo. The Headers tab is selected, showing a red box around it. The Body tab is also visible. The JSON body is defined as follows:

```
1 {  
2     "name": "walk dog",  
3     "isComplete": true  
4 }
```

Below the request details, the response section is shown with a red box around the Headers tab. It displays the following headers:

- Content-Type → application/json; charset=utf-8
- Date → Fri, 27 Apr 2018 18:32:32 GMT
- Location → https://localhost/api/Todo/6

The status is 201 Created and the time taken was 148 ms.

The Location header URI can be used to access the new item.

## Update

Add the following `Update` method:

```
[HttpPut("{id}")]
public IActionResult Update(long id, [FromBody] TodoItem item)
{
    if (item == null || item.Id != id)
    {
        return BadRequest();
    }

    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    todo.IsComplete = item.IsComplete;
    todo.Name = item.Name;

    _context.TodoItems.Update(todo);
    _context.SaveChanges();
    return NoContent();
}
```

```
[HttpPut("{id}")]
public IActionResult Update(long id, TodoItem item)
{
    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    todo.IsComplete = item.IsComplete;
    todo.Name = item.Name;

    _context.TodoItems.Update(todo);
    _context.SaveChanges();
    return NoContent();
}
```

`Update` is similar to `Create`, except it uses HTTP PUT. The response is [204 \(No Content\)](#). According to the HTTP specification, a PUT request requires the client to send the entire updated entity, not just the deltas. To support partial updates, use HTTP PATCH.

Use Postman to update the to-do item's name to "walk cat":

The screenshot shows the Postman application interface. The request method is set to `PUT` and the URL is `https://localhost:44375/api/todo/1`. The `Body` tab is selected, showing the raw JSON payload:

```
{
  "name": "walk cat",
  "isComplete": true
}
```

The `Content-Type` is set to `JSON (application/json)`. The response status is `204 No Content` with a response time of `70 ms`.

## Delete

Add the following `Delete` method:

```
[HttpDelete("{id}")]
public IActionResult Delete(long id)
{
    var todo = _context.TodoItems.Find(id);
    if (todo == null)
    {
        return NotFound();
    }

    _context.TodoItems.Remove(todo);
    _context.SaveChanges();
    return NoContent();
}
```

The `Delete` response is [204 \(No Content\)](#).

Use Postman to delete the to-do item:

The screenshot shows the Postman application window. At the top, there's a menu bar with File, Edit, View, Help, and a toolbar with New, Import, Runner, and a search bar labeled "My Workspace". Below the toolbar, there are three tabs for environments: "https://localhost:4437" (selected), "https://localhost:4437" (disabled), and "https://localhost:4437" (disabled). To the right of the tabs, it says "No Environment".

In the main area, a red box highlights the "DELETE" dropdown menu. Next to it is the URL "https://localhost:44375/api/todo/1". To the right of the URL are "Params" and a "Send" button. Below the URL, there are tabs for Authorization, Headers, Body, Pre-request Script, and Tests. The "Authorization" tab is selected, showing "No Auth" selected in a dropdown. A note below says: "The authorization header will be automatically generated when you send the request. [Learn more about authorization](#)". To the right of this note, another note says: "This request does not use any authorization. [Learn more about authorization](#)".

At the bottom of the main area, there are tabs for Body, Cookies, Headers (4), and Test Results. The "Body" tab is selected. It has sub-options for Pretty, Raw, Preview, and Text (which is currently selected). Below these options is a large text input area containing the number "1".

At the very bottom of the window, there are icons for refresh, search, and file operations, along with a "BUILD" dropdown.

# Develop ASP.NET Core apps using a file watcher

7/14/2018 • 3 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Victor Hurdugaci](#)

`dotnet watch` is a tool that runs a [.NET Core CLI](#) command when source files change. For example, a file change can trigger compilation, test execution, or deployment.

This tutorial uses an existing web API with two endpoints: one that returns a sum and one that returns a product. The product method has a bug, which is fixed in this tutorial.

Download the [sample app](#). It consists of two projects: *WebApp* (an ASP.NET Core web API) and *WebAppTests* (unit tests for the web API).

In a command shell, navigate to the *WebApp* folder. Run the following command:

```
dotnet run
```

The console output shows messages similar to the following (indicating that the app is running and awaiting requests):

```
$ dotnet run
Hosting environment: Development
Content root path: C:/Docs/aspnetcore/tutorials/dotnet-watch/sample/WebApp
Now listening on: http://localhost:5000
Application started. Press Ctrl+C to shut down.
```

In a web browser, navigate to `http://localhost:<port number>/api/math/sum?a=4&b=5`. You should see the result of 9.

Navigate to the product API (`http://localhost:<port number>/api/math/product?a=4&b=5`). It returns 9, not 20 as you'd expect. That problem is fixed later in the tutorial.

## Add `dotnet watch` to a project

The `dotnet watch` file watcher tool is included with version 2.1.300 of the .NET Core SDK. The following steps are required when using an earlier version of the .NET Core SDK.

1. Add a `Microsoft.DotNet.Watcher.Tools` package reference to the `.csproj` file:

```
<ItemGroup>
<DotNetCliToolReference Include="Microsoft.DotNet.Watcher.Tools" Version="2.0.0" />
</ItemGroup>
```

1. Install the `Microsoft.DotNet.Watcher.Tools` package by running the following command:

```
dotnet restore
```

## Run .NET Core CLI commands using `dotnet watch`

Any .NET Core CLI command can be run with `dotnet watch`. For example:

COMMAND	COMMAND WITH WATCH
<code>dotnet run</code>	<code>dotnet watch run</code>
<code>dotnet run -f netcoreapp2.0</code>	<code>dotnet watch run -f netcoreapp2.0</code>
<code>dotnet run -f netcoreapp2.0 -- --arg1</code>	<code>dotnet watch run -f netcoreapp2.0 -- --arg1</code>
<code>dotnet test</code>	<code>dotnet watch test</code>

Run `dotnet watch run` in the *WebApp* folder. The console output indicates `watch` has started.

## Make changes with `dotnet watch`

Make sure `dotnet watch` is running.

Fix the bug in the `Product` method of *MathController.cs* so it returns the product and not the sum:

```
public static int Product(int a, int b)
{
    return a * b;
}
```

Save the file. The console output indicates that `dotnet watch` detected a file change and restarted the app.

Verify `http://localhost:<port number>/api/math/product?a=4&b=5` returns the correct result.

## Run tests using `dotnet watch`

1. Change the `Product` method of *MathController.cs* back to returning the sum. Save the file.
2. In a command shell, navigate to the *WebAppTests* folder.
3. Run `dotnet restore`.
4. Run `dotnet watch test`. Its output indicates that a test failed and that the watcher is awaiting file changes:

```
Total tests: 2. Passed: 1. Failed: 1. Skipped: 0.
Test Run Failed.
```

5. Fix the `Product` method code so it returns the product. Save the file.

`dotnet watch` detects the file change and reruns the tests. The console output indicates the tests passed.

## Customize files list to watch

By default, `dotnet-watch` tracks all files matching the following glob patterns:

- `**/*.cs`
- `*.csproj`
- `**/*.resx`

More items can be added to the watch list by editing the *.csproj* file. Items can be specified individually or by using

glob patterns.

```
<ItemGroup>
    <!-- extends watching group to include *.js files -->
    <Watch Include="**\*.js" Exclude="node_modules\**\*;**\*.js.map;obj\**\*;bin\**\*" />
</ItemGroup>
```

## Opt-out of files to be watched

`dotnet-watch` can be configured to ignore its default settings. To ignore specific files, add the `Watch="false"` attribute to an item's definition in the `.csproj` file:

```
<ItemGroup>
    <!-- exclude Generated.cs from dotnet-watch -->
    <Compile Include="Generated.cs" Watch="false" />

    <!-- exclude Strings.resx from dotnet-watch -->
    <EmbeddedResource Include="Strings.resx" Watch="false" />

    <!-- exclude changes in this referenced project -->
    <ProjectReference Include=".\\ClassLibrary1\\ClassLibrary1.csproj" Watch="false" />
</ItemGroup>
```

## Custom watch projects

`dotnet-watch` isn't restricted to C# projects. Custom watch projects can be created to handle different scenarios. Consider the following project layout:

- **test**
  - *UnitTests/UnitTests.csproj*
  - *IntegrationTests/IntegrationTests.csproj*

If the goal is to watch both projects, create a custom project file configured to watch both projects:

```
<Project>
    <ItemGroup>
        <TestProjects Include="**\*.csproj" />
        <Watch Include="**\*.cs" />
    </ItemGroup>

    <Target Name="Test">
        <MSBuild Targets="VSTest" Projects="@({TestProjects})" />
    </Target>

    <Import Project="$(MSBuildExtensionsPath)\\Microsoft.Common.targets" />
</Project>
```

To start file watching on both projects, change to the `test` folder. Execute the following command:

```
dotnet watch msbuild /t:Test
```

VSTest executes when any file changes in either test project.

`dotnet-watch` in GitHub

`dotnet-watch` is part of the GitHub [DotNetTools repository](#).

# Create backend services for native mobile apps with ASP.NET Core

6/21/2018 • 7 minutes to read • [Edit Online](#)

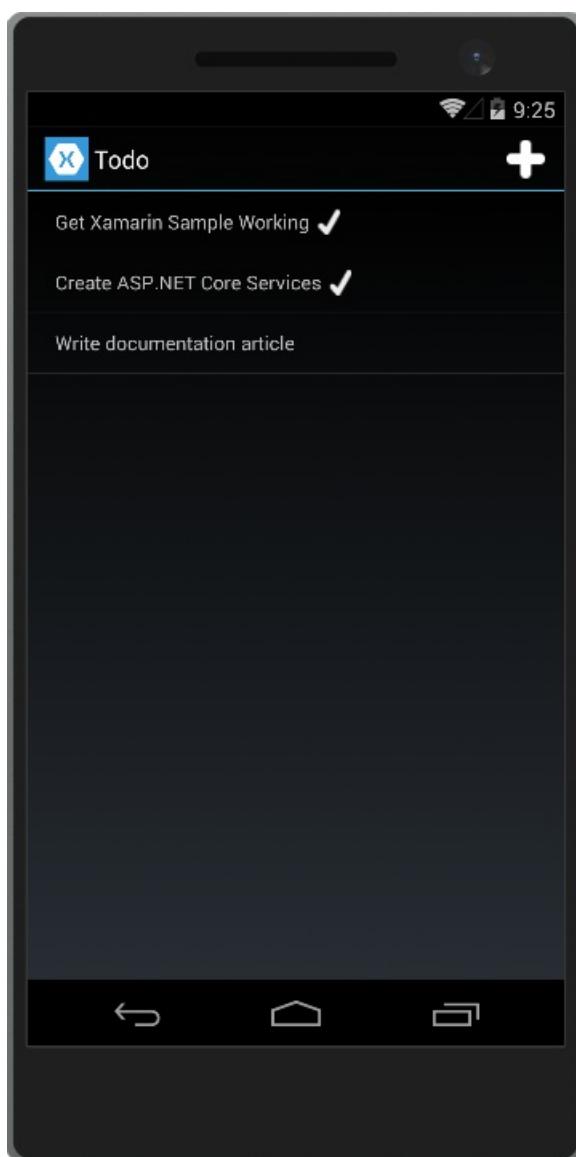

By [Steve Smith](#)

Mobile apps can easily communicate with ASP.NET Core backend services.

[View or download sample backend services code](#)

## The Sample Native Mobile App

This tutorial demonstrates how to create backend services using ASP.NET Core MVC to support native mobile apps. It uses the [Xamarin Forms ToDoRest app](#) as its native client, which includes separate native clients for Android, iOS, Windows Universal, and Window Phone devices. You can follow the linked tutorial to create the native app (and install the necessary free Xamarin tools), as well as download the Xamarin sample solution. The Xamarin sample includes an ASP.NET Web API 2 services project, which this article's ASP.NET Core app replaces (with no changes required by the client).

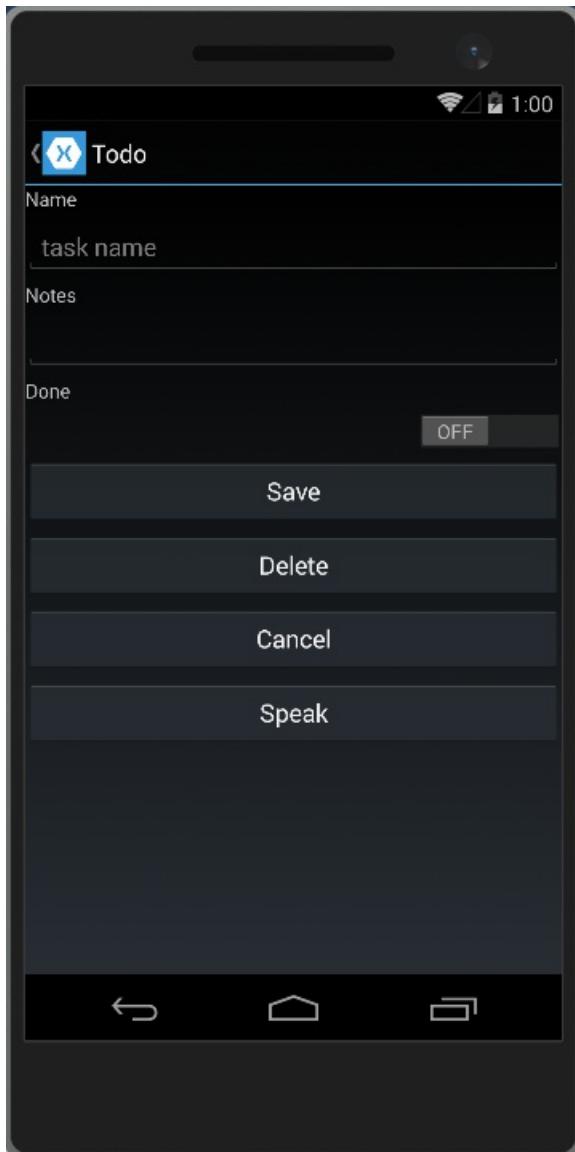

### Features

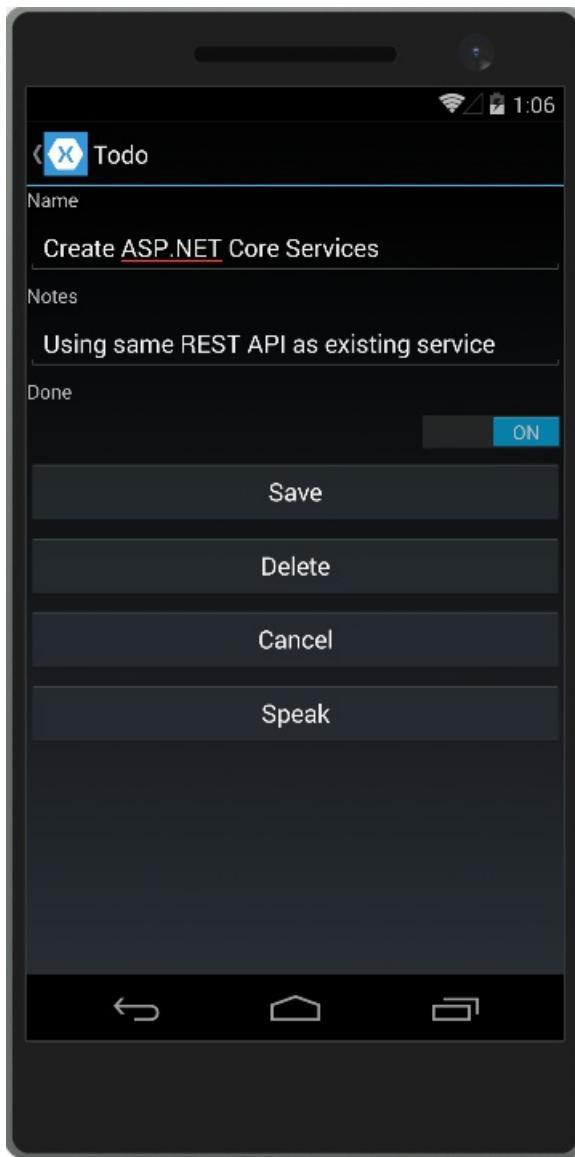

The ToDoRest app supports listing, adding, deleting, and updating To-Do items. Each item has an ID, a Name, Notes, and a property indicating whether it's been Done yet.

The main view of the items, as shown above, lists each item's name and indicates if it's done with a checkmark.

Tapping the  icon opens an add item dialog:

Tapping an item on the main list screen opens up an edit dialog where the item's Name, Notes, and Done settings can be modified, or the item can be deleted:

This sample is configured by default to use backend services hosted at developer.xamarin.com, which allow read-only operations. To test it out yourself against the ASP.NET Core app created in the next section running on your computer, you'll need to update the app's `RestUrl` constant. Navigate to the `ToDoREST` project and open the `Constants.cs` file. Replace the `RestUrl` with a URL that includes your machine's IP address (not localhost or 127.0.0.1, since this address is used from the device emulator, not from your machine). Include the port number as well (5000). In order to test that your services work with a device, ensure you don't have an active firewall blocking access to this port.

```
// URL of REST service (Xamarin ReadOnly Service)
//public static string RestUrl = "http://developer.xamarin.com:8081/api/todoitems{0}";

// use your machine's IP address
public static string RestUrl = "http://192.168.1.207:5000/api/todoitems/{0}";
```

## Creating the ASP.NET Core Project

Create a new ASP.NET Core Web Application in Visual Studio. Choose the Web API template and No Authentication. Name the project `ToDoApi`.

Select a template:

**ASP.NET Core Templates**

Empty

Web API

Web Application

A project template for creating an ASP.NET Core application with an example Controller for a RESTful HTTP service. This template can also be used for ASP.NET MVC Views and Controllers.

[Learn more](#)[Change Authentication](#)Authentication: **No Authentication**

Microsoft Azure

 Host in the cloud

App Service

[OK](#)[Cancel](#)

The application should respond to all requests made to port 5000. Update *Program.cs* to include

```
.UseUrls("http://*:5000")
```

 to achieve this:

```
var host = new WebHostBuilder()
    .UseKestrel()
    .UseUrls("http://*:5000")
    .UseContentRoot(Directory.GetCurrentDirectory())
    .UseIISIntegration()
    .UseStartup<Startup>()
    .Build();
```

**NOTE**

Make sure you run the application directly, rather than behind IIS Express, which ignores non-local requests by default. Run [dotnet run](#) from a command prompt, or choose the application name profile from the Debug Target dropdown in the Visual Studio toolbar.

Add a model class to represent To-Do items. Mark required fields using the `[Required]` attribute:

```

using System.ComponentModel.DataAnnotations;

namespace ToDoApi.Models
{
    public class ToDoItem
    {
        [Required]
        public string ID { get; set; }

        [Required]
        public string Name { get; set; }

        [Required]
        public string Notes { get; set; }

        public bool Done { get; set; }
    }
}

```

The API methods require some way to work with data. Use the same `IToDoRepository` interface the original Xamarin sample uses:

```

using System.Collections.Generic;
using ToDoApi.Models;

namespace ToDoApi.Interfaces
{
    public interface IToDoRepository
    {
        bool DoesItemExist(string id);
        IEnumerable<ToDoItem> All { get; }
        ToDoItem Find(string id);
        void Insert(ToDoItem item);
        void Update(ToDoItem item);
        void Delete(string id);
    }
}

```

For this sample, the implementation just uses a private collection of items:

```

using System.Collections.Generic;
using System.Linq;
using ToDoApi.Interfaces;
using ToDoApi.Models;

namespace ToDoApi.Services
{
    public class ToDoRepository : IToDoRepository
    {
        private List<ToDoItem> _ToDoList;

        public ToDoRepository()
        {
            InitializeData();
        }

        public IEnumerable<ToDoItem> All
        {
            get { return _ToDoList; }
        }

        public bool DoesItemExist(string id)
        {
            return _ToDoList.Any(item => item.ID == id);
        }
    }
}

```

```

        }

        public ToDoItem Find(string id)
        {
            return _toDoList.FirstOrDefault(item => item.ID == id);
        }

        public void Insert(ToDoItem item)
        {
            _toDoList.Add(item);
        }

        public void Update(ToDoItem item)
        {
            var todoItem = this.Find(item.ID);
            var index = _toDoList.IndexOf(todoItem);
            _toDoList.RemoveAt(index);
            _toDoList.Insert(index, item);
        }

        public void Delete(string id)
        {
            _toDoList.Remove(this.Find(id));
        }

        private void InitializeData()
        {
            _toDoList = new List<ToDoItem>();

            var todoItem1 = new ToDoItem
            {
                ID = "6bb8a868-dba1-4f1a-93b7-24ebce87e243",
                Name = "Learn app development",
                Notes = "Attend Xamarin University",
                Done = true
            };

            var todoItem2 = new ToDoItem
            {
                ID = "b94afb54-a1cb-4313-8af3-b7511551b33b",
                Name = "Develop apps",
                Notes = "Use Xamarin Studio/Visual Studio",
                Done = false
            };

            var todoItem3 = new ToDoItem
            {
                ID = "ecfa6f80-3671-4911-aabe-63cc442c1ecf",
                Name = "Publish apps",
                Notes = "All app stores",
                Done = false,
            };

            _toDoList.Add(todoItem1);
            _toDoList.Add(todoItem2);
            _toDoList.Add(todoItem3);
        }
    }
}

```

Configure the implementation in *Startup.cs*:

```
public void ConfigureServices(IServiceCollection services)
{
    // Add framework services.
    services.AddMvc();

    services.AddSingleton<IToDoRepository, ToDoRepository>();
}
```

At this point, you're ready to create the *ToDoItemsController*.

**TIP**

Learn more about creating web APIs in [Build your first Web API with ASP.NET Core MVC and Visual Studio](#).

## Creating the Controller

Add a new controller to the project, *ToDoItemsController*. It should inherit from `Microsoft.AspNetCore.Mvc.Controller`. Add a `[Route]` attribute to indicate that the controller will handle requests made to paths starting with `api/todoitems`. The `[controller]` token in the route is replaced by the name of the controller (omitting the `Controller` suffix), and is especially helpful for global routes. Learn more about [routing](#).

The controller requires an `IToDoRepository` to function; request an instance of this type through the controller's constructor. At runtime, this instance will be provided using the framework's support for [dependency injection](#).

```
using System;
using Microsoft.AspNetCore.Http;
using Microsoft.AspNetCore.Mvc;
using ToDoApi.Interfaces;
using ToDoApi.Models;

namespace ToDoApi.Controllers
{
    [Route("api/[controller]")]
    public class ToDoItemsController : Controller
    {
        private readonly IToDoRepository _ToDoRepository;

        public ToDoItemsController(IToDoRepository ToDoRepository)
        {
            _ToDoRepository = ToDoRepository;
        }
    }
}
```

This API supports four different HTTP verbs to perform CRUD (Create, Read, Update, Delete) operations on the data source. The simplest of these is the Read operation, which corresponds to an HTTP GET request.

### Reading Items

Requesting a list of items is done with a GET request to the `List` method. The `[HttpGet]` attribute on the `List` method indicates that this action should only handle GET requests. The route for this action is the route specified on the controller. You don't necessarily need to use the action name as part of the route. You just need to ensure each action has a unique and unambiguous route. Routing attributes can be applied at both the controller and method levels to build up specific routes.

```
[HttpGet]
public IActionResult List()
{
    return Ok(_todoRepository.All);
}
```

The `List` method returns a 200 OK response code and all of the ToDo items, serialized as JSON.

You can test your new API method using a variety of tools, such as [Postman](#), shown here:

The screenshot shows the Postman application interface. At the top, there are tabs for 'Runner', 'Import', 'Builder', 'Team Library', and status indicators for 'SYNC OFF' and notifications. Below the header, the URL is set to `http://192.168.1.207:5000/api/todoitems`. The main interface shows a 'GET' request selected, with the URL again displayed. Below the request type are tabs for 'Authorization', 'Headers', 'Body', 'Pre-request Script', 'Tests', and 'Generate Code'. The 'Headers' tab is currently active. In the 'Body' section, there are tabs for 'Pretty', 'Raw', 'Preview', and 'JSON'. The 'Pretty' tab is selected, displaying a JSON array of three todo items. Each item has an ID, name, notes, and a 'done' status. The 'Status' field indicates a '200 OK' response, and the 'Time' taken is 69 ms.

id	name	notes	done
6bb8a868-dba1-4f1a-93b7-24ebce87e243	Learn app development	Attend Xamarin University	true
b94afb54-a1cb-4313-8af3-b7511551b33b	Develop apps	Use Xamarin Studio/Visual Studio	false
ecfa6f80-3671-4911-aabe-63cc442c1ecf	Publish apps	All app stores	false

## Creating Items

By convention, creating new data items is mapped to the HTTP POST verb. The `Create` method has an `[HttpPost]` attribute applied to it, and accepts a `ToDoItem` instance. Since the `item` argument will be passed in the body of the POST, this parameter is decorated with the `[FromBody]` attribute.

Inside the method, the item is checked for validity and prior existence in the data store, and if no issues occur, it's added using the repository. Checking `ModelState.IsValid` performs [model validation](#), and should be done in every API method that accepts user input.

```
[HttpPost]
public IActionResult Create([FromBody] ToDoItem item)
{
    try
    {
        if (item == null || !ModelState.IsValid)
        {
            return BadRequest(ErrorCode.TodoItemNameAndNotesRequired.ToString());
        }
        bool itemExists = _ToDoRepository.DoesItemExist(item.ID);
        if (itemExists)
        {
            return StatusCode(StatusCodes.Status409Conflict, ErrorCode.TodoItemIDInUse.ToString());
        }
        _ToDoRepository.Insert(item);
    }
    catch (Exception)
    {
        return BadRequest(ErrorCode.CouldNotCreateItem.ToString());
    }
    return Ok(item);
}
```

The sample uses an enum containing error codes that are passed to the mobile client:

```
public enum ErrorCode
{
    TodoItemNameAndNotesRequired,
    TodoItemIDInUse,
    RecordNotFound,
    CouldNotCreateItem,
    CouldNotUpdateItem,
    CouldNotDeleteItem
}
```

Test adding new items using Postman by choosing the POST verb providing the new object in JSON format in the Body of the request. You should also add a request header specifying a Content-Type of application/json.

The method returns the newly created item in the response.

## Updating Items

Modifying records is done using HTTP PUT requests. Other than this change, the `Edit` method is almost identical to `Create`. Note that if the record isn't found, the `Edit` action will return a `NotFound` (404) response.

```
[HttpPut]
public IActionResult Edit([FromBody] ToDoItem item)
{
    try
    {
        if (item == null || !ModelState.IsValid)
        {
            return BadRequest(ErrorCode.TodoItemNameAndNotesRequired.ToString());
        }
        var existingItem = _todoRepository.Find(item.ID);
        if (existingItem == null)
        {
            return NotFound(ErrorCode.RecordNotFound.ToString());
        }
        _todoRepository.Update(item);
    }
    catch (Exception)
    {
        return BadRequest(ErrorCode.CouldNotUpdateItem.ToString());
    }
    return NoContent();
}
```

To test with Postman, change the verb to PUT. Specify the updated object data in the Body of the request.

The screenshot shows the Postman application interface. The top navigation bar includes 'Runner', 'Import', 'Builder' (which is selected), 'Team Library', and various status indicators like 'SYNC OFF'. Below the header, the URL is set to `http://192.168.1.207:5000/a`. The main area shows a 'PUT' request to `http://192.168.1.207:5000/api/todoitems`. The 'Body' tab is active, showing a raw JSON payload:

```
1 {  
2     "ID": "6bb8b868-dba1-4f1a-93b7-24ebce87243",  
3     "Name": "An UPDATED Test Item",  
4     "Notes": "Some updated notes",  
5     "Done": true  
6 }
```

The 'Headers' section contains two entries: 'Content-Type: application/json' and 'Accept: application/json'. The 'Body' section is set to 'raw' and 'JSON (application/json)'. The response section shows a successful `204 No Content` response with a time of `91 ms`.

This method returns a `NoContent` (204) response when successful, for consistency with the pre-existing API.

## Deleting Items

Deleting records is accomplished by making DELETE requests to the service, and passing the ID of the item to be deleted. As with updates, requests for items that don't exist will receive `NotFound` responses. Otherwise, a successful request will get a `NoContent` (204) response.

```
[HttpDelete("{id}")]
public IActionResult Delete(string id)
{
    try
    {
        var item = _todoRepository.Find(id);
        if (item == null)
        {
            return NotFound(ErrorCode.RecordNotFound.ToString());
        }
        _todoRepository.Delete(id);
    }
    catch (Exception)
    {
        return BadRequest(ErrorCode.CouldNotDeleteItem.ToString());
    }
    return NoContent();
}
```

Note that when testing the delete functionality, nothing is required in the Body of the request.

The screenshot shows the Postman application interface. At the top, there are tabs for Runner, Import, Builder (which is selected), and Team Library. On the right side of the header, there are icons for a gear (Sync Off), a bell, and a dropdown menu. Below the header, the URL `http://192.168.1.207:5000/a` is entered in the address bar, along with a plus sign icon for creating new requests. To the right of the URL, it says "No environment" with a dropdown arrow and an eye icon. The main workspace shows a **DELETE** request to `http://192.168.1.207:5000/api/todoitems/6bb8b8`. The "Body" tab is selected, showing options for form-data, x-www-form-urlencoded, raw, and binary, with "raw" selected and "JSON (application/json)" chosen. A large text area for the request body is present but empty. Other tabs include Headers (2), Pre-request Script, Tests, and Generate Code. Below the request area, the response section is shown with "Body" selected. It displays the status `204 No Content` and time `91 ms`. It includes Pretty, Raw, Preview, and HTML buttons, and a search icon. A large text area for the response body is also empty.

## Common Web API Conventions

As you develop the backend services for your app, you will want to come up with a consistent set of conventions or policies for handling cross-cutting concerns. For example, in the service shown above, requests for specific records that weren't found received a `NotFound` response, rather than a `BadRequest` response. Similarly, commands made to this service that passed in model bound types always checked `ModelState.IsValid` and returned a `BadRequest` for invalid model types.

Once you've identified a common policy for your APIs, you can usually encapsulate it in a [filter](#). Learn more about [how to encapsulate common API policies in ASP.NET Core MVC applications](#).

# ASP.NET Core fundamentals

7/2/2018 • 7 minutes to read • [Edit Online](#)

An ASP.NET Core application is a console app that creates a web server in its `Main` method:

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

```
using Microsoft.AspNetCore;
using Microsoft.AspNetCore.Hosting;

namespace aspnetcoreapp
{
    public class Program
    {
        public static void Main(string[] args)
        {
            BuildWebHost(args).Run();
        }

        public static IWebHost BuildWebHost(string[] args) =>
            WebHost.CreateDefaultBuilder(args)
                .UseStartup<Startup>()
                .Build();
    }
}
```

The `Main` method invokes `WebHost.CreateDefaultBuilder`, which follows the builder pattern to create a web application host. The builder has methods that define the web server (for example, `UseKestrel`) and the startup class (`UseStartup`). In the preceding example, the `Kestrel` web server is automatically allocated. ASP.NET Core's web host attempts to run on IIS, if available. Other web servers, such as `HTTP.sys`, can be used by invoking the appropriate extension method. `UseStartup` is explained further in the next section.

`IWebHostBuilder`, the return type of the `WebHost.CreateDefaultBuilder` invocation, provides many optional methods. Some of these methods include `UseHttpSys` for hosting the app in `HTTP.sys` and `UseContentRoot` for specifying the root content directory. The `Build` and `Run` methods build the `IWebHost` object that hosts the app and begins listening for HTTP requests.

## Startup

The `UseStartup` method on `WebHostBuilder` specifies the `Startup` class for your app:

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

```
public class Program
{
    public static void Main(string[] args)
    {
        BuildWebHost(args).Run();
    }

    public static IWebHost BuildWebHost(string[] args) =>
        WebHost.CreateDefaultBuilder(args)
            .UseStartup<Startup>()
            .Build();
}
```

The `Startup` class is where you define the request handling pipeline and where any services needed by the app are configured. The `Startup` class must be public and contain the following methods:

```
public class Startup
{
    // This method gets called by the runtime. Use this method
    // to add services to the container.
    public void ConfigureServices(IServiceCollection services)
    {

        // This method gets called by the runtime. Use this method
        // to configure the HTTP request pipeline.
        public void Configure(IApplicationBuilder app)
        {
        }
}
```

`ConfigureServices` defines the [Services](#) used by your app (for example, ASP.NET Core MVC, Entity Framework Core, Identity). `Configure` defines the [middleware](#) for the request pipeline.

For more information, see [Application startup](#).

## Content root

The content root is the base path to any content used by the app, such as views, [Razor Pages](#), and static assets. By default, the content root is the same as application base path for the executable hosting the app.

## Web root

The web root of an app is the directory in the project containing public, static resources, such as CSS, JavaScript, and image files.

## Dependency injection (services)

A service is a component that's intended for common consumption in an app. Services are made available through [dependency injection \(DI\)](#). ASP.NET Core includes a native [Inversion of Control](#) (IoC) container that supports [constructor injection](#) by default. You can replace the default native container if you wish. In addition to its loose coupling benefit, DI makes services available throughout your app (for example, [logging](#)).

For more information, see [Dependency injection](#).

## Middleware

In ASP.NET Core, you compose your request pipeline using [middleware](#). ASP.NET Core middleware performs

asynchronous logic on an `HttpContext` and then either invokes the next middleware in the sequence or terminates the request directly. A middleware component called "XYZ" is added by invoking an `UseXYZ` extension method in the `Configure` method.

ASP.NET Core includes a rich set of built-in middleware:

- [Static files](#)
- [Routing](#)
- [Authentication](#)
- [Response Compression Middleware](#)
- [URL Rewriting Middleware](#)

OWIN-based middleware is available for ASP.NET Core apps, and you can write your own custom middleware.

For more information, see [Middleware](#) and [Open Web Interface for .NET \(OWIN\)](#).

## Initiate HTTP requests

For information about using `IHttpClientFactory` to access `HttpClient` instances to make HTTP requests, see [Initiate HTTP requests](#).

## Environments

Environments, such as "Development" and "Production", are a first-class notion in ASP.NET Core and can be set using environment variables.

For more information, see [Use multiple environments](#).

## Configuration

ASP.NET Core uses a configuration model based on name-value pairs. The configuration model isn't based on `System.Configuration` or `web.config`. Configuration obtains settings from an ordered set of configuration providers. The built-in configuration providers support a variety of file formats (XML, JSON, INI) and environment variables to enable environment-based configuration. You can also write your own custom configuration providers.

For more information, see [Configuration](#).

## Logging

ASP.NET Core supports a logging API that works with a variety of logging providers. Built-in providers support sending logs to one or more destinations. Third-party logging frameworks can be used.

For more information, see [Logging](#)

## Error handling

ASP.NET Core has built-in features for handling errors in apps, including a developer exception page, custom error pages, static status code pages, and startup exception handling.

For more information, see [how to handle errors](#).

## Routing

ASP.NET Core offers features for routing of app requests to route handlers.

For more information, see [Routing](#).

## File providers

ASP.NET Core abstracts file system access through the use of File Providers, which offers a common interface for working with files across platforms.

For more information, see [File Providers](#).

## Static files

Static files middleware serves static files, such as HTML, CSS, image, and JavaScript.

For more information, see [Static files](#).

## Hosting

ASP.NET Core apps configure and launch a *host*, which is responsible for app startup and lifetime management.

For more information, see [Host in ASP.NET Core](#).

## Session and app state

ASP.NET Core offers several approaches to preserve session and app state while the user browses a web app.

For more information, see [Session and app state](#).

## Servers

The ASP.NET Core hosting model doesn't directly listen for requests. The hosting model relies on an HTTP server implementation to forward the request to the app. The forwarded request is wrapped as a set of feature objects that can be accessed through interfaces. ASP.NET Core includes a managed, cross-platform web server, called **Kestrel**. Kestrel is often run behind a production web server, such as [IIS](#) or [Nginx](#). Kestrel can be run as an edge server.

For more information, see [Servers](#) and the following topics:

- [Kestrel](#)
- [ASP.NET Core Module](#)
- [HTTP.sys](#) (formerly called [WebListener](#))

## Globalization and localization

Creating a multilingual website with ASP.NET Core allows your site to reach a wider audience. ASP.NET Core provides services and middleware for localizing into different languages and cultures.

For more information, see [Globalization and localization](#).

## Request features

Web server implementation details related to HTTP requests and responses are defined in interfaces. These interfaces are used by server implementations and middleware to create and modify the app's hosting pipeline.

For more information, see [Request Features](#).

## Background tasks

Background tasks are implemented as *hosted services*. A hosted service is a class with background task logic that implements the [IHostedService](#) interface.

For more information, see [Background tasks with hosted services](#).

## Open Web Interface for .NET (OWIN)

ASP.NET Core supports the Open Web Interface for .NET (OWIN). OWIN allows web apps to be decoupled from web servers.

For more information, see [Open Web Interface for .NET \(OWIN\)](#).

## WebSockets

[WebSocket](#) is a protocol that enables two-way persistent communication channels over TCP connections. It's used for apps such as chat, stock tickers, games, and anywhere you desire real-time functionality in a web app. ASP.NET Core supports web socket features.

For more information, see [WebSockets](#).

## Microsoft.AspNetCore.App metapackage

The [Microsoft.AspNetCore.App](#) metapackage simplifies package management. For more information, see [Microsoft.AspNetCore.App metapackage](#).

## Microsoft.AspNetCore.All metapackage

The [Microsoft.AspNetCore.All](#) metapackage for ASP.NET Core includes:

- All supported packages by the ASP.NET Core team.
- All supported packages by Entity Framework Core.
- Internal and 3rd-party dependencies used by ASP.NET Core and Entity Framework Core.

For more information, see [Microsoft.AspNetCore.All metapackage](#).

## .NET Core vs. .NET Framework runtime

An ASP.NET Core app can target the .NET Core or .NET Framework runtime.

For more information, see [Choosing between .NET Core and .NET Framework](#).

## Choose between ASP.NET Core and ASP.NET

For more information on choosing between ASP.NET Core and ASP.NET, see [Choose between ASP.NET Core and ASP.NET](#).

# Application startup in ASP.NET Core

7/14/2018 • 8 minutes to read • [Edit Online](#)

By [Steve Smith](#), [Tom Dykstra](#), and [Luke Latham](#)

The `Startup` class configures services and the app's request pipeline.

## The Startup class

ASP.NET Core apps use a `Startup` class, which is named `Startup` by convention. The `Startup` class:

- Can optionally include a `ConfigureServices` method to configure the app's services.
- Must include a `Configure` method to create the app's request processing pipeline.

`ConfigureServices` and `Configure` are called by the runtime when the app starts:

```
public class Startup
{
    // Use this method to add services to the container.
    public void ConfigureServices(IServiceCollection services)
    {
        ...
    }

    // Use this method to configure the HTTP request pipeline.
    public void Configure(IApplicationBuilder app)
    {
        ...
    }
}
```

Specify the `Startup` class with the `WebHostBuilderExtensions.UseStartup<TStartup>` method:

```
public class Program
{
    public static void Main(string[] args)
    {
        BuildWebHost(args).Run();
    }

    public static IWebHost BuildWebHost(string[] args) =>
        WebHost.CreateDefaultBuilder(args)
            .UseStartup<Startup>()
            .Build();
}
```

The `Startup` class constructor accepts dependencies defined by the host. A common use of [dependency injection](#) into the `Startup` class is to inject:

- [IHostingEnvironment](#) to configure services by environment.
- [IConfiguration](#) to configure the app during startup.

```

public class Startup
{
    public Startup(IHostingEnvironment env, IConfiguration config)
    {
        HostingEnvironment = env;
        Configuration = config;
    }

    public IHostingEnvironment HostingEnvironment { get; }
    public IConfiguration Configuration { get; }

    public void ConfigureServices(IServiceCollection services)
    {
        if (HostingEnvironment.IsDevelopment())
        {
            // Development configuration
        }
        else
        {
            // Staging/Production configuration
        }

        // Configuration is available during startup. Examples:
        // Configuration["key"]
        // Configuration["subsection:suboption1"]
    }
}

```

An alternative to injecting `IHostingEnvironment` is to use a conventions-based approach. The app can define separate `Startup` classes for different environments (for example, `StartupDevelopment`), and the appropriate `Startup` class is selected at runtime. The class whose name suffix matches the current environment is prioritized. If the app is run in the Development environment and includes both a `Startup` class and a `StartupDevelopment` class, the `StartupDevelopment` class is used. For more information, see [Use multiple environments](#).

To learn more about `WebHostBuilder`, see the [Hosting](#) topic. For information on handling errors during startup, see [Startup exception handling](#).

## The ConfigureServices method

The `ConfigureServices` method is:

- Optional
- Called by the web host before the `Configure` method to configure the app's services.
- Where [configuration options](#) are set by convention.

Adding services to the service container makes them available within the app and in the `Configure` method. The services are resolved via [dependency injection](#) or from `IApplicationBuilder.ApplicationServices`.

The web host may configure some services before `Startup` methods are called. Details are available in the [Host in ASP.NET Core](#) topic.

For features that require substantial setup, there are `Add[Service]` extension methods on `IServiceCollection`. A typical web app registers services for Entity Framework, Identity, and MVC:

```

public void ConfigureServices(IServiceCollection services)
{
    // Add framework services.
    services.AddDbContext<ApplicationDbContext>(options =>
        options.UseSqlServer(Configuration.GetConnectionString("DefaultConnection")));

    services.AddIdentity< ApplicationUser, IdentityRole>()
        .AddEntityFrameworkStores<ApplicationDbContext>()
        .AddDefaultTokenProviders();

    services.AddMvc();

    // Add application services.
    services.AddTransient< IEmailSender, AuthMessageSender>();
    services.AddTransient< ISmsSender, AuthMessageSender>();
}

```

## SetCompatibilityVersion for ASP.NET Core MVC

The `SetCompatibilityVersion` method allows an app to opt-in or opt-out of potentially breaking behavior changes introduced in ASP.NET MVC Core 2.1+. These potentially breaking behavior changes are generally in how the MVC subsystem behaves and how **your code** is called by the runtime. By opting in, you get the latest behavior, and the long-term behavior of ASP.NET Core.

The following code sets the compatibility mode to ASP.NET Core 2.1:

```

public void ConfigureServices(IServiceCollection services)
{
    services.AddMvc()
        .SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
}

```

We recommend you test your application using the latest version (`CompatibilityVersion.Version_2_1`). We anticipate that most applications will not have breaking behavior changes using the latest version.

Applications that call `SetCompatibilityVersion(CompatibilityVersion.Version_2_0)` are protected from potentially breaking behavior changes introduced in the ASP.NET Core 2.1 MVC and later 2.x versions. This protection:

- Does not apply to all 2.1 and later changes, it's targeted to potentially breaking ASP.NET Core runtime behavior changes in the MVC subsystem.
- Does not extend to the next major version.

The default compatibility for ASP.NET Core 2.1 and later 2.x applications that do **not** call `SetCompatibilityVersion` is 2.0 compatibility. That is, not calling `SetCompatibilityVersion` is the same as calling `SetCompatibilityVersion(CompatibilityVersion.Version_2_0)`.

The following code sets the compatibility mode to ASP.NET Core 2.1, except for the following behaviors:

- [AllowCombiningAuthorizeFilters](#)
- [InputFormatterExceptionPolicy](#)

```

public void ConfigureServices(IServiceCollection services)
{
    services.AddMvc()
        // Include the 2.1 behaviors
        .SetCompatibilityVersion(CompatibilityVersion.Version_2_1)
        // Except for the following.
        .AddMvcOptions(options =>
    {
        // Don't combine authorize filters (keep 2.0 behavior).
        options.AllowCombiningAuthorizeFilters = false;
        // All exceptions thrown by an IInputFormatter will be treated
        // as model state errors (keep 2.0 behavior).
        options.InputFormatterExceptionPolicy =
            InputFormatterExceptionPolicy.AllExceptions;
    });
}

```

For apps that encounter breaking behavior changes, using the appropriate compatibility switches:

- Allows you to use the latest release and opt out of specific breaking behavior changes.
- Gives you time to update your app so it works with the latest changes.

The [MvcOptions](#) class source comments have a good explanation of what changed and why the changes are an improvement for most users.

At some future date, there will be an [ASP.NET Core 3.0 version](#). Old behaviors supported by compatibility switches will be removed in the 3.0 version. We feel these are positive changes benefitting nearly all users. By introducing these changes now, most apps can benefit now, and the others will have time to update their applications.

## Services available in Startup

The web host provides some services that are available to the `Startup` class constructor. The app adds additional services via `ConfigureServices`. Both the host and app services are then available in `Configure` and throughout the application.

## The Configure method

The `Configure` method is used to specify how the app responds to HTTP requests. The request pipeline is configured by adding [middleware](#) components to an `IApplicationBuilder` instance. `IApplicationBuilder` is available to the `Configure` method, but it isn't registered in the service container. Hosting creates an `IApplicationBuilder` and passes it directly to `Configure` ([reference source](#)).

The [ASP.NET Core templates](#) configure the pipeline with support for a developer exception page, [BrowserLink](#), error pages, static files, and ASP.NET MVC:

```
public void Configure(IApplicationBuilder app, IHostingEnvironment env)
{
    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
        app.UseBrowserLink();
    }
    else
    {
        app.UseExceptionHandler("/Error");
    }

    app.UseStaticFiles();

    app.UseMvc(routes =>
    {
        routes.MapRoute(
            name: "default",
            template: "{controller}/{action=Index}/{id?}");
    });
}
```

Each `use` extension method adds a middleware component to the request pipeline. For instance, the `useMvc` extension method adds the [Routing Middleware](#) to the request pipeline and configures [MVC](#) as the default handler.

Each middleware component in the request pipeline is responsible for invoking the next component in the pipeline or short-circuiting the chain, if appropriate. If short-circuiting doesn't occur along the middleware chain, each middleware has a second chance to process the request before it's sent to the client.

Additional services, such as `IHostingEnvironment` and `ILoggerFactory`, may also be specified in the method signature. When specified, additional services are injected if they're available.

For more information on how to use `IApplicationBuilder` and the order of middleware processing, see [Middleware](#).

## Convenience methods

`ConfigureServices` and `Configure` convenience methods can be used instead of specifying a `Startup` class. Multiple calls to `ConfigureServices` append to one another. Multiple calls to `Configure` use the last method call.

```

public class Program
{
    public static IHostingEnvironment HostingEnvironment { get; set; }
    public static IConfiguration Configuration { get; set; }

    public static void Main(string[] args)
    {
        BuildWebHost(args).Run();
    }

    public static IWebHost BuildWebHost(string[] args) =>
        WebHost.CreateDefaultBuilder(args)
            .ConfigureAppConfiguration((hostingContext, config) =>
            {
                HostingEnvironment = hostingContext.HostingEnvironment;
                Configuration = config.Build();
            })
            .ConfigureServices(services =>
            {
                services.AddMvc();
            })
            .Configure(app =>
            {
                if (HostingEnvironment.IsDevelopment())
                {
                    app.UseDeveloperExceptionPage();
                }
                else
                {
                    app.UseExceptionHandler("/Error");
                }

                // Configuration is available during startup. Examples:
                // Configuration["key"]
                // Configuration["subsection:suboption1"]

                app.UseMvcWithDefaultRoute();
                app.UseStaticFiles();
            })
            .Build();
    }
}

```

## Startup filters

Use [IStartupFilter](#) to configure middleware at the beginning or end of an app's [Configure](#) middleware pipeline. [IStartupFilter](#) is useful to ensure that a middleware runs before or after middleware added by libraries at the start or end of the app's request processing pipeline.

[IStartupFilter](#) implements a single method, [Configure](#), which receives and returns an [Action<IApplicationBuilder>](#). An [IApplicationBuilder](#) defines a class to configure an app's request pipeline. For more information, see [Create a middleware pipeline with IApplicationBuilder](#).

Each [IStartupFilter](#) implements one or more middlewares in the request pipeline. The filters are invoked in the order they were added to the service container. Filters may add middleware before or after passing control to the next filter, thus they append to the beginning or end of the app pipeline.

The [sample app \(how to download\)](#) demonstrates how to register a middleware with [IStartupFilter](#). The sample app includes a middleware that sets an options value from a query string parameter:

```

public class RequestSetOptionsMiddleware
{
    private readonly RequestDelegate _next;
    private IOptions<AppOptions> _injectedOptions;

    public RequestSetOptionsMiddleware(
        RequestDelegate next, IOptions<AppOptions> injectedOptions)
    {
        _next = next;
        _injectedOptions = injectedOptions;
    }

    public async Task Invoke(HttpContext httpContext)
    {
        Console.WriteLine("RequestSetOptionsMiddleware.Invoke");

        var option = httpContext.Request.Query["option"];

        if (!string.IsNullOrWhiteSpace(option))
        {
            _injectedOptions.Value.Option = WebUtility.HtmlEncode(option);
        }

        await _next(httpContext);
    }
}

```

The `RequestSetOptionsMiddleware` is configured in the `RequestSetOptionsStartupFilter` class:

```

public class RequestSetOptionsStartupFilter : IStartupFilter
{
    public Action<IApplicationBuilder> Configure(Action<IApplicationBuilder> next)
    {
        return builder =>
        {
            builder.UseMiddleware<RequestSetOptionsMiddleware>();
            next(builder);
        };
    }
}

```

The `IStartupFilter` is registered in the service container in `ConfigureServices`:

```

public void ConfigureServices(IServiceCollection services)
{
    services.AddTransient<IStartupFilter, RequestSetOptionsStartupFilter>();
    services.AddMvc();
}

```

When a query string parameter for `option` is provided, the middleware processes the value assignment before the MVC middleware renders the response:

Middleware execution order is set by the order of `IStartupFilter` registrations:

- Multiple `IStartupFilter` implementations may interact with the same objects. If ordering is important, order their `IStartupFilter` service registrations to match the order that their middlewares should run.
- Libraries may add middleware with one or more `IStartupFilter` implementations that run before or after other app middleware registered with `IStartupFilter`. To invoke an `IStartupFilter` middleware before a middleware added by a library's `IStartupFilter`, position the service registration before the library is added to the service container. To invoke it afterward, position the service registration after the library is added.

## Adding configuration at startup from an external assembly

An `IHostingStartup` implementation allows adding enhancements to an app at startup from an external assembly outside of the app's `Startup` class. For more information, see [Enhance an app from an external assembly](#).

# Dependency injection in ASP.NET Core

6/21/2018 • 17 minutes to read • [Edit Online](#)

By [Steve Smith](#) and [Scott Addie](#)

ASP.NET Core is designed from the ground up to support and leverage dependency injection. ASP.NET Core applications can leverage built-in framework services by having them injected into methods in the Startup class, and application services can be configured for injection as well. The default services container provided by ASP.NET Core provides a minimal feature set and isn't intended to replace other containers.

[View or download sample code \(how to download\)](#)

## What is dependency injection?

Dependency injection (DI) is a technique for achieving loose coupling between objects and their collaborators, or dependencies. Rather than directly instantiating collaborators, or using static references, the objects a class needs in order to perform its actions are provided to the class in some fashion. Most often, classes will declare their dependencies via their constructor, allowing them to follow the [Explicit Dependencies Principle](#). This approach is known as "constructor injection".

When classes are designed with DI in mind, they're more loosely coupled because they don't have direct, hard-coded dependencies on their collaborators. This follows the [Dependency Inversion Principle](#), which states that "*high level modules shouldn't depend on low level modules; both should depend on abstractions.*" Instead of referencing specific implementations, classes request abstractions (typically `interfaces`) which are provided to them when the class is constructed. Extracting dependencies into interfaces and providing implementations of these interfaces as parameters is also an example of the [Strategy design pattern](#).

When a system is designed to use DI, with many classes requesting their dependencies via their constructor (or properties), it's helpful to have a class dedicated to creating these classes with their associated dependencies. These classes are referred to as *containers*, or more specifically, [Inversion of Control \(IoC\)](#) containers or Dependency Injection (DI) containers. A container is essentially a factory that's responsible for providing instances of types that are requested from it. If a given type has declared that it has dependencies, and the container has been configured to provide the dependency types, it will create the dependencies as part of creating the requested instance. In this way, complex dependency graphs can be provided to classes without the need for any hard-coded object construction. In addition to creating objects with their dependencies, containers typically manage object lifetimes within the application.

ASP.NET Core includes a simple built-in container (represented by the `IServiceProvider` interface) that supports constructor injection by default, and ASP.NET makes certain services available through DI. ASP.NET's container refers to the types it manages as *services*. Throughout the rest of this article, *services* will refer to types that are managed by ASP.NET Core's IoC container. You configure the built-in container's services in the `ConfigureServices` method in your application's `Startup` class.

#### NOTE

Martin Fowler has written an extensive article on [Inversion of Control Containers and the Dependency Injection Pattern](#). Microsoft Patterns and Practices also has a great description of [Dependency Injection](#).

#### NOTE

This article covers Dependency Injection as it applies to all ASP.NET applications. Dependency Injection within MVC controllers is covered in [Dependency Injection and Controllers](#).

### Constructor injection behavior

Constructor injection requires that the constructor in question be *public*. Otherwise, your app will throw an `InvalidOperationException`:

A suitable constructor for type 'YourType' couldn't be located. Ensure the type is concrete and services are registered for all parameters of a public constructor.

Constructor injection requires that only one applicable constructor exist. Constructor overloads are supported, but only one overload can exist whose arguments can all be fulfilled by dependency injection. If more than one exists, your app will throw an `InvalidOperationException`:

Multiple constructors accepting all given argument types have been found in type 'YourType'. There should only be one applicable constructor.

Constructors can accept arguments that are not provided by dependency injection, but these must support default values. For example:

```
// throws InvalidOperationException: Unable to resolve service for type 'System.String'...
public CharactersController(ICharacterRepository characterRepository, string title)
{
    _characterRepository = characterRepository;
    _title = title;
}

// runs without error
public CharactersController(ICharacterRepository characterRepository, string title =
"Characters")
{
    _characterRepository = characterRepository;
    _title = title;
}
```

## Using framework-provided services

The `ConfigureServices` method in the `Startup` class is responsible for defining the services the application will use, including platform features like Entity Framework Core and ASP.NET Core MVC. Initially, the `IServiceCollection` provided to `ConfigureServices` has the following services defined (depending on [how the host was configured](#)):

SERVICE TYPE	LIFETIME
<code>Microsoft.AspNetCore.Hosting.IHostingEnvironment</code>	Singleton

Service Type	Lifetime
Microsoft.Extensions.Logging.ILoggerFactory	Singleton
Microsoft.Extensions.Logging.ILogger<T>	Singleton
Microsoft.AspNetCore.Hosting.Builder.IApplicationBuilderFactory	Transient
Microsoft.AspNetCore.Http.IHttpContextFactory	Transient
Microsoft.Extensions.Options.IOptions<T>	Singleton
System.Diagnostics.DiagnosticSource	Singleton
System.Diagnostics.DiagnosticListener	Singleton
Microsoft.AspNetCore.Hosting.IStartupFilter	Transient
Microsoft.Extensions.ObjectPool.ObjectPoolProvider	Singleton
Microsoft.Extensions.Options.IConfigureOptions<T>	Transient
Microsoft.AspNetCore.Hosting.Server.IServer	Singleton
Microsoft.AspNetCore.Hosting.IStartup	Singleton
Microsoft.AspNetCore.Hosting.IApplicationLifetime	Singleton

Below is an example of how to add additional services to the container using a number of extension methods like `AddDbContext`, `AddIdentity`, and `AddMvc`.

```
// This method gets called by the runtime. Use this method to add services to the container.
public void ConfigureServices(IServiceCollection services)
{
    // Add framework services.
    services.AddDbContext<ApplicationContext>(options =>
        options.UseSqlServer(Configuration.GetConnectionString("DefaultConnection")));

    services.AddIdentity< ApplicationUser, IdentityRole >()
        .AddEntityFrameworkStores< ApplicationContext >()
        .AddDefaultTokenProviders();

    services.AddMvc();

    // Add application services.
    services.AddTransient< IEmailSender, AuthMessageSender >();
    services.AddTransient< ISmsSender, AuthMessageSender >();
}
```

The features and middleware provided by ASP.NET, such as MVC, follow a convention of using a single `AddServiceName` extension method to register all of the services required by that feature.

#### TIP

You can request certain framework-provided services within `Startup` methods through their parameter lists - see [Application Startup](#) for more details.

## Registering services

You can register your own application services as follows. The first generic type represents the type (typically an interface) that will be requested from the container. The second generic type represents the concrete type that will be instantiated by the container and used to fulfill such requests.

```
services.AddTransient<IEmailSender, AuthMessageSender>();
services.AddTransient<ISmsSender, AuthMessageSender>();
```

#### NOTE

Each `services.Add<ServiceName>` extension method adds (and potentially configures) services. For example, `services.AddMvc()` adds the services MVC requires. It's recommended that you follow this convention, placing extension methods in the `Microsoft.Extensions.DependencyInjection` namespace, to encapsulate groups of service registrations.

The `AddTransient` method is used to map abstract types to concrete services that are instantiated separately for every object that requires it. This is known as the service's *lifetime*, and additional lifetime options are described below. It's important to choose an appropriate lifetime for each of the services you register. Should a new instance of the service be provided to each class that requests it? Should one instance be used throughout a given web request? Or should a single instance be used for the lifetime of the application?

In the sample for this article, there's a simple controller that displays character names, called `CharactersController`. Its `Index` method displays the current list of characters that have been stored in the application, and initializes the collection with a handful of characters if none exist. Note that although this application uses Entity Framework Core and the `ApplicationDbContext` class for its persistence, none of that's apparent in the controller. Instead, the specific data access mechanism has been abstracted behind an interface, `ICharacterRepository`, which follows the [repository pattern](#). An instance of `ICharacterRepository` is requested via the constructor and assigned to a private field, which is then used to access characters as necessary.

```

public class CharactersController : Controller
{
    private readonly ICharacterRepository _characterRepository;

    public CharactersController(ICharacterRepository characterRepository)
    {
        _characterRepository = characterRepository;
    }

    // GET: /characters/
    public IActionResult Index()
    {
        PopulateCharactersIfNoneExist();
        var characters = _characterRepository.ListAll();

        return View(characters);
    }

    private void PopulateCharactersIfNoneExist()
    {
        if (!_characterRepository.ListAll().Any())
        {
            _characterRepository.Add(new Character("Darth Maul"));
            _characterRepository.Add(new Character("Darth Vader"));
            _characterRepository.Add(new Character("Yoda"));
            _characterRepository.Add(new Character("Mace Windu"));
        }
    }
}

```

The `ICharacterRepository` defines the two methods the controller needs to work with `Character` instances.

```

using System.Collections.Generic;
using DependencyInjectionSample.Models;

namespace DependencyInjectionSample.Interfaces
{
    public interface ICharacterRepository
    {
        IEnumerable<Character> ListAll();
        void Add(Character character);
    }
}

```

This interface is in turn implemented by a concrete type, `CharacterRepository`, that's used at runtime.

#### NOTE

The way DI is used with the `CharacterRepository` class is a general model you can follow for all of your application services, not just in "repositories" or data access classes.

```

using System.Collections.Generic;
using System.Linq;
using DependencyInjectionSample.Interfaces;

namespace DependencyInjectionSample.Models
{
    public class CharacterRepository : ICharacterRepository
    {
        private readonly ApplicationDbContext _dbContext;

        public CharacterRepository(ApplicationDbContext dbContext)
        {
            _dbContext = dbContext;
        }

        public IEnumerable<Character> ListAll()
        {
            return _dbContext.Characters.AsEnumerable();
        }

        public void Add(Character character)
        {
            _dbContext.Characters.Add(character);
            _dbContext.SaveChanges();
        }
    }
}

```

Note that `CharacterRepository` requests an `ApplicationDbContext` in its constructor. It's not unusual for dependency injection to be used in a chained fashion like this, with each requested dependency in turn requesting its own dependencies. The container is responsible for resolving all of the dependencies in the graph and returning the fully resolved service.

#### **NOTE**

Creating the requested object, and all of the objects it requires, and all of the objects those require, is sometimes referred to as an *object graph*. Likewise, the collective set of dependencies that must be resolved is typically referred to as a *dependency tree* or *dependency graph*.

In this case, both `ICharacterRepository` and in turn `ApplicationDbContext` must be registered with the services container in `ConfigureServices` in `Startup`. `ApplicationDbContext` is configured with the call to the extension method `AddDbContext<T>`. The following code shows the registration of the `CharacterRepository` type.

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddDbContext<ApplicationContext>(options =>
        options.UseInMemoryDatabase()
    );

    // Add framework services.
    services.AddMvc();

    // Register application services.
    services.AddScoped<ICharacterRepository, CharacterRepository>();
    services.AddTransient<IOperationTransient, Operation>();
    services.AddScoped<IOperationScoped, Operation>();
    services.AddSingleton<IOperationSingleton, Operation>();
    services.AddSingleton<IOperationSingletonInstance>(new Operation(Guid.Empty));
    services.AddTransient<OperationService, OperationService>();
}
```

Entity Framework contexts should be added to the services container using the `Scoped` lifetime. This is taken care of automatically if you use the helper methods as shown above. Repositories that will make use of Entity Framework should use the same lifetime.

#### **WARNING**

The main danger to be wary of is resolving a `Scoped` service from a singleton. It's likely in such a case that the service will have incorrect state when processing subsequent requests.

Services that have dependencies should register them in the container. If a service's constructor requires a primitive, such as a `string`, this can be injected by using [configuration](#) and the [options pattern](#).

## Service lifetimes and registration options

ASP.NET services can be configured with the following lifetimes:

### **Transient**

Transient lifetime services are created each time they're requested. This lifetime works best for lightweight, stateless services.

### **Scoped**

Scoped lifetime services are created once per request.

#### **WARNING**

If you're using a scoped service in a middleware, inject the service into the `Invoke` or `InvokeAsync` method. Don't inject via constructor injection because it forces the service to behave like a singleton.

### **Singleton**

Singleton lifetime services are created the first time they're requested (or when `ConfigureServices` is run if you specify an instance there) and then every subsequent request will use the same instance. If your application requires singleton behavior, allowing the services container to manage the service's lifetime is recommended instead of implementing the singleton design pattern and managing your object's lifetime in the class yourself.

Services can be registered with the container in several ways. We have already seen how to register a service implementation with a given type by specifying the concrete type to use. In addition, a factory can be specified, which will then be used to create the instance on demand. The third approach is to directly specify the instance of the type to use, in which case the container will never attempt to create an instance (nor will it dispose of the instance).

To demonstrate the difference between these lifetime and registration options, consider a simple interface that represents one or more tasks as an *operation* with a unique identifier, `OperationId`. Depending on how we configure the lifetime for this service, the container will provide either the same or different instances of the service to the requesting class. To make it clear which lifetime is being requested, we will create one type per lifetime option:

```
using System;

namespace DependencyInjectionSample.Interfaces
{
    public interface IOperation
    {
        Guid OperationId { get; }
    }

    public interface IOperationTransient : IOperation
    {
    }

    public interface IOperationScoped : IOperation
    {
    }

    public interface IOperationSingleton : IOperation
    {
    }

    public interface IOperationSingletonInstance : IOperation
    {
    }
}
```

We implement these interfaces using a single class, `Operation`, that accepts a `Guid` in its constructor, or uses a new `Guid` if none is provided.

Next, in `ConfigureServices`, each type is added to the container according to its named lifetime:

```
services.AddScoped<ICharacterRepository, CharacterRepository>();
services.AddTransient<IOperationTransient, Operation>();
services.AddScoped<IOperationScoped, Operation>();
services.AddSingleton<IOperationSingleton, Operation>();
services.AddSingleton<IOperationSingletonInstance>(new Operation(Guid.Empty));
services.AddTransient<OperationService, OperationService>();
}
```

Note that the `IOperationSingletonInstance` service is using a specific instance with a known ID of `Guid.Empty` so it will be clear when this type is in use (its `Guid` will be all zeroes). We have also registered an `OperationService` that depends on each of the other `Operation` types, so that it will be clear within a request whether this service is getting the same instance as the controller, or a new one, for each operation type. All this service does is expose its dependencies as properties, so they can be displayed in the view.

```
using DependencyInjectionSample.Interfaces;

namespace DependencyInjectionSample.Services
{
    public class OperationService
    {
        public IOperationTransient TransientOperation { get; }
        public IOperationScoped ScopedOperation { get; }
        public IOperationSingleton SingletonOperation { get; }
        public IOperationSingletonInstance SingletonInstanceOperation { get; }

        public OperationService(IOperationTransient transientOperation,
            IOperationScoped scopedOperation,
            IOperationSingleton singletonOperation,
            IOperationSingletonInstance instanceOperation)
        {
            TransientOperation = transientOperation;
            ScopedOperation = scopedOperation;
            SingletonOperation = singletonOperation;
            SingletonInstanceOperation = instanceOperation;
        }
    }
}
```

To demonstrate the object lifetimes within and between separate individual requests to the application, the sample includes an `OperationsController` that requests each kind of `IOperation` type as well as an `OperationService`. The `Index` action then displays all of the controller's and service's `OperationId` values.

```

using DependencyInjectionSample.Interfaces;
using DependencyInjectionSample.Services;
using Microsoft.AspNetCore.Mvc;

namespace DependencyInjectionSample.Controllers
{
    public class OperationsController : Controller
    {
        private readonly OperationService _operationService;
        private readonly IOperationTransient _transientOperation;
        private readonly IOperationScoped _scopedOperation;
        private readonly IOperationSingleton _singletonOperation;
        private readonly IOperationSingletonInstance _singletonInstanceOperation;

        public OperationsController(OperationService operationService,
            IOperationTransient transientOperation,
            IOperationScoped scopedOperation,
            IOperationSingleton singletonOperation,
            IOperationSingletonInstance singletonInstanceOperation)
        {
            _operationService = operationService;
            _transientOperation = transientOperation;
            _scopedOperation = scopedOperation;
            _singletonOperation = singletonOperation;
            _singletonInstanceOperation = singletonInstanceOperation;
        }

        public IActionResult Index()
        {
            // ViewBag contains controller-requested services
            ViewBag.Transient = _transientOperation;
            ViewBag.Scoped = _scopedOperation;
            ViewBag.Singleton = _singletonOperation;
            ViewBag.SingletonInstance = _singletonInstanceOperation;

            // operation service has its own requested services
            ViewBag.Service = _operationService;
            return View();
        }
    }
}

```

Now two separate requests are made to this controller action:

Lifetimes - Dependency × +

localhost:40931/operations

DependencyInjectionSample Home Characters Register Log in

## Lifetimes

Request One

Controller Operations

<b>Transient</b>	e6fee2c8-2122-4d10-aa05-cb376042e2c7
<b>Scoped</b>	661bff78-5ecb-4758-ae43-ec22a3e0babe
<b>Singleton</b>	93c52d5b-4c51-4907-a4d2-6a336a797ce6
<b>Instance</b>	00000000-0000-0000-0000-000000000000

OperationService Operations

<b>Transient</b>	a379336b-3fd0-49ac-b176-bae7c27c5de5
<b>Scoped</b>	661bff78-5ecb-4758-ae43-ec22a3e0babe
<b>Singleton</b>	93c52d5b-4c51-4907-a4d2-6a336a797ce6
<b>Instance</b>	00000000-0000-0000-0000-000000000000

Observe which of the `OperationId` values vary within a request, and between requests.

- *Transient* objects are always different; a new instance is provided to every controller and every service.
- *Scoped* objects are the same within a request, but different across different requests
- *Singleton* objects are the same for every object and every request (regardless of whether an instance is provided in `ConfigureServices`)

## Resolve a scoped service within the application scope

Create an `IServiceScope` with `IServiceScopeFactory.CreateScope()` to resolve a scoped service within the app's scope. This approach is useful to access a scoped service at startup to run initialization tasks. The following example shows how to obtain a context for the `MyScopedService` in `Program.Main`:

```
public static void Main(string[] args)
{
    var host = BuildWebHost(args);

    using (var serviceScope = host.Services.CreateScope())
    {
        var services = serviceScope.ServiceProvider;

        try
        {
            var serviceContext = services.GetRequiredService<MyScopedService>();
            // Use the context here
        }
        catch (Exception ex)
        {
            var logger = services.GetRequiredService<ILogger<Program>>();
            logger.LogError(ex, "An error occurred.");
        }
    }

    host.Run();
}
```

## Scope validation

When the app is running in the Development environment on ASP.NET Core 2.0 or later, the default service provider performs checks to verify that:

- Scoped services aren't directly or indirectly resolved from the root service provider.
- Scoped services aren't directly or indirectly injected into singletons.

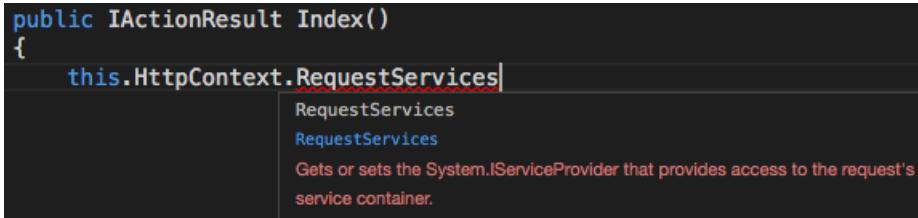

The root service provider is created when `BuildServiceProvider` is called. The root service provider's lifetime corresponds to the app/server's lifetime when the provider starts with the app and is disposed when the app shuts down.

Scoped services are disposed by the container that created them. If a scoped service is created in the root container, the service's lifetime is effectively promoted to singleton because it's only disposed by the root container when app/server is shut down. Validating service scopes catches these situations when `BuildServiceProvider` is called.

For more information, see [Scope validation in the Web Host topic](#).

## Request Services

The services available within an ASP.NET request from `HttpContext` are exposed through the `RequestServices` collection.

Request Services represent the services you configure and request as part of your application.

When your objects specify dependencies, these are satisfied by the types found in

`RequestServices`, not `ApplicationServices`.

Generally, you shouldn't use these properties directly, preferring instead to request the types your classes you require via your class's constructor, and letting the framework inject these dependencies. This yields classes that are easier to test (see [Test and debug](#)) and are more loosely coupled.

### NOTE

Prefer requesting dependencies as constructor parameters to accessing the `RequestServices` collection.

## Designing services for dependency injection

You should design your services to use dependency injection to get their collaborators. This means avoiding the use of stateful static method calls (which result in a code smell known as [static cling](#)) and the direct instantiation of dependent classes within your services. It may help to remember the phrase, [New is Glue](#), when choosing whether to instantiate a type or to request it via dependency injection. By following the [SOLID Principles of Object Oriented Design](#), your classes will naturally tend to be small, well-factored, and easily tested.

What if you find that your classes tend to have way too many dependencies being injected? This is generally a sign that your class is trying to do too much, and is probably violating SRP - the

[Single Responsibility Principle](#). See if you can refactor the class by moving some of its responsibilities into a new class. Keep in mind that your `Controller` classes should be focused on UI concerns, so business rules and data access implementation details should be kept in classes appropriate to these [separate concerns](#).

With regards to data access specifically, you can inject the `DbContext` into your controllers (assuming you've added EF to the services container in `ConfigureServices`). Some developers prefer to use a repository interface to the database rather than injecting the `DbContext` directly. Using an interface to encapsulate the data access logic in one place can minimize how many places you will have to change when your database changes.

### Disposing of services

The container will call `Dispose` for `IDisposable` types it creates. However, if you add an instance to the container yourself, it will not be disposed.

Example:

```
// Services implement IDisposable:  
public class Service1 : IDisposable {}  
public class Service2 : IDisposable {}  
public class Service3 : IDisposable {}  
  
public interface ISomeService {}  
public class SomeServiceImplementation : ISomeService, IDisposable {}  
  
public void ConfigureServices(IServiceCollection services)  
{  
    // container will create the instance(s) of these types and will dispose them  
    services.AddScoped<Service1>();  
    services.AddSingleton<Service2>();  
    services.AddSingleton<ISomeService>(sp => new SomeServiceImplementation());  
  
    // container didn't create instance so it will NOT dispose it  
    services.AddSingleton<Service3>(new Service3());  
    services.AddSingleton(new Service3());  
}
```

#### NOTE

In version 1.0, the container called dispose on *all* `IDisposable` objects, including those it didn't create.

## Replacing the default services container

The built-in services container is meant to serve the basic needs of the framework and most consumer applications built on it. However, developers can replace the built-in container with their preferred container. The `ConfigureServices` method typically returns `void`, but if its signature is changed to return `IServiceProvider`, a different container can be configured and returned. There are many IOC containers available for .NET. In this example, the [Autofac](#) package is used.

First, install the appropriate container package(s):

- `Autofac`
- `Autofac.Extensions.DependencyInjection`

Next, configure the container in `ConfigureServices` and return an `IServiceProvider`:

```
public IServiceProvider ConfigureServices(IServiceCollection services)
{
    services.AddMvc();
    // Add other framework services

    // Add Autofac
    var containerBuilder = new ContainerBuilder();
    containerBuilder.RegisterModule<DefaultModule>();
    containerBuilder.Populate(services);
    var container = containerBuilder.Build();
    return new AutofacServiceProvider(container);
}
```

#### NOTE

When using a third-party DI container, you must change `ConfigureServices` so that it returns `IServiceProvider` instead of `void`.

Finally, configure Autofac as normal in `DefaultModule`:

```
public class DefaultModule : Module
{
    protected override void Load(ContainerBuilder builder)
    {
        builder.RegisterType<CharacterRepository>().As<ICharacterRepository>();
    }
}
```

At runtime, Autofac will be used to resolve types and inject dependencies. [Learn more about using Autofac and ASP.NET Core](#).

#### Thread safety

Singleton services need to be thread safe. If a singleton service has a dependency on a transient service, the transient service may also need to be thread safe depending how it's used by the singleton.

## Recommendations

When working with dependency injection, keep the following recommendations in mind:

- DI is for objects that have complex dependencies. Controllers, services, adapters, and repositories are all examples of objects that might be added to DI.
- Avoid storing data and configuration directly in DI. For example, a user's shopping cart shouldn't typically be added to the services container. Configuration should use the [options pattern](#). Similarly, avoid "data holder" objects that only exist to allow access to some other object. It's better to request the actual item needed via DI, if possible.
- Avoid static access to services.
- Avoid service location in your application code.
- Avoid static access to `HttpContext`.

Like all sets of recommendations, you may encounter situations where ignoring one is required. We have found exceptions to be rare -- mostly very special cases within the framework itself.

Dependency injection is an *alternative* to static/global object access patterns. You may not be able

to realize the benefits of DI if you mix it with static object access.

# ASP.NET Core Middleware

6/21/2018 • 9 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Steve Smith](#)

[View or download sample code](#) ([how to download](#))

## What is middleware?

Middleware is software that's assembled into an application pipeline to handle requests and responses. Each component:

- Chooses whether to pass the request to the next component in the pipeline.
- Can perform work before and after the next component in the pipeline is invoked.

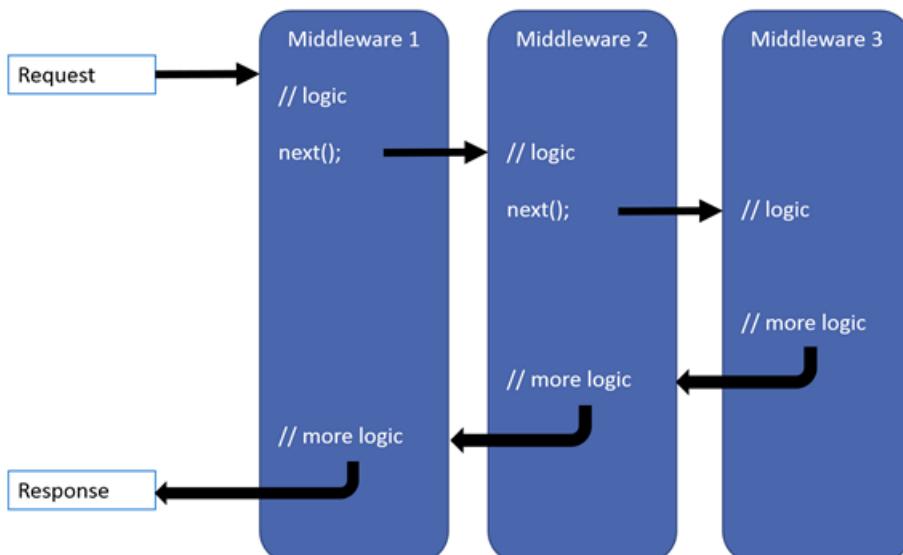

Request delegates are used to build the request pipeline. The request delegates handle each HTTP request.

Request delegates are configured using [Run](#), [Map](#), and [Use](#) extension methods. An individual request delegate can be specified in-line as an anonymous method (called in-line middleware), or it can be defined in a reusable class. These reusable classes and in-line anonymous methods are *middleware*, or *middleware components*. Each middleware component in the request pipeline is responsible for invoking the next component in the pipeline, or short-circuiting the chain if appropriate.

[Migrate HTTP Modules to Middleware](#) explains the difference between request pipelines in ASP.NET Core and ASP.NET 4.x and provides more middleware samples.

## Creating a middleware pipeline with `IApplicationBuilder`

The ASP.NET Core request pipeline consists of a sequence of request delegates, called one after the other, as this diagram shows (the thread of execution follows the black arrows):

Each delegate can perform operations before and after the next delegate. A delegate can also decide to not pass a request to the next delegate, which is called short-circuiting the request pipeline. Short-circuiting is often desirable because it avoids unnecessary work. For example, the static file middleware can return a request for a static file and short-circuit the rest of the pipeline. Exception-handling delegates need to be called early in the pipeline, so they

can catch exceptions that occur in later stages of the pipeline.

The simplest possible ASP.NET Core app sets up a single request delegate that handles all requests. This case doesn't include an actual request pipeline. Instead, a single anonymous function is called in response to every HTTP request.

```
using Microsoft.AspNetCore.Builder;
using Microsoft.AspNetCore.Hosting;
using Microsoft.AspNetCore.Http;

public class Startup
{
    public void Configure(IApplicationBuilder app)
    {
        app.Run(async context =>
        {
            await context.Response.WriteAsync("Hello, World!");
        });
    }
}
```

The first `app.Run` delegate terminates the pipeline.

You can chain multiple request delegates together with `app.Use`. The `next` parameter represents the next delegate in the pipeline. (Remember that you can short-circuit the pipeline by *not* calling the `next` parameter.) You can typically perform actions both before and after the next delegate, as this example demonstrates:

```
public class Startup
{
    public void Configure(IApplicationBuilder app)
    {
        app.Use(async (context, next) =>
        {
            // Do work that doesn't write to the Response.
            await next.Invoke();
            // Do logging or other work that doesn't write to the Response.
        });

        app.Run(async context =>
        {
            await context.Response.WriteAsync("Hello from 2nd delegate.");
        });
    }
}
```

### WARNING

Don't call `next.Invoke` after the response has been sent to the client. Changes to `HttpResponse` after the response has started will throw an exception. For example, changes such as setting headers, status code, etc, will throw an exception.

Writing to the response body after calling `next`:

- May cause a protocol violation. For example, writing more than the stated `content-length`.
- May corrupt the body format. For example, writing an HTML footer to a CSS file.

`HttpResponse.HasStarted` is a useful hint to indicate if headers have been sent and/or the body has been written to.

## Ordering

The order that middleware components are added in the `Configure` method defines the order in which they're

invoked on requests, and the reverse order for the response. This ordering is critical for security, performance, and functionality.

The Configure method (shown below) adds the following middleware components:

1. Exception/error handling
2. Static file server
3. Authentication
4. MVC

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

```
public void Configure(IApplicationBuilder app)
{
    app.UseExceptionHandler("/Home/Error"); // Call first to catch exceptions
                                                // thrown in the following middleware.

    app.UseStaticFiles();                      // Return static files and end pipeline.

    app.UseAuthentication();                  // Authenticate before you access
                                                // secure resources.

    app.UseMvcWithDefaultRoute();            // Add MVC to the request pipeline.
}
```

In the code above, `UseExceptionHandler` is the first middleware component added to the pipeline—therefore, it catches any exceptions that occur in later calls.

The static file middleware is called early in the pipeline so it can handle requests and short-circuit without going through the remaining components. The static file middleware provides **no** authorization checks. Any files served by it, including those under `wwwroot`, are publicly available. See [Static files](#) for an approach to secure static files.

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

If the request isn't handled by the static file middleware, it's passed on to the Identity middleware (`app.UseAuthentication`), which performs authentication. Identity doesn't short-circuit unauthenticated requests. Although Identity authenticates requests, authorization (and rejection) occurs only after MVC selects a specific Razor Page or controller and action.

The following example demonstrates a middleware ordering where requests for static files are handled by the static file middleware before the response compression middleware. Static files are not compressed with this ordering of the middleware. The MVC responses from `UseMvcWithDefaultRoute` can be compressed.

```
public void Configure(IApplicationBuilder app)
{
    app.UseStaticFiles();          // Static files not compressed
                                  // by middleware.

    app.UseResponseCompression();
    app.UseMvcWithDefaultRoute();
}
```

## Use, Run, and Map

You configure the HTTP pipeline using `Use`, `Run`, and `Map`. The `Use` method can short-circuit the pipeline (that is, if it doesn't call a `next` request delegate). `Run` is a convention, and some middleware components may expose `Run[Middleware]` methods that run at the end of the pipeline.

`Map*` extensions are used as a convention for branching the pipeline. `Map` branches the request pipeline based on matches of the given request path. If the request path starts with the given path, the branch is executed.

```
public class Startup
{
    private static void HandleMapTest1(IApplicationBuilder app)
    {
        app.Run(async context =>
        {
            await context.Response.WriteAsync("Map Test 1");
        });
    }

    private static void HandleMapTest2(IApplicationBuilder app)
    {
        app.Run(async context =>
        {
            await context.Response.WriteAsync("Map Test 2");
        });
    }

    public void Configure(IApplicationBuilder app)
    {
        app.Map("/map1", HandleMapTest1);

        app.Map("/map2", HandleMapTest2);

        app.Run(async context =>
        {
            await context.Response.WriteAsync("Hello from non-Map delegate. <p>");
        });
    }
}
```

The following table shows the requests and responses from `http://localhost:1234` using the previous code:

REQUEST	RESPONSE
localhost:1234	Hello from non-Map delegate.
localhost:1234/map1	Map Test 1
localhost:1234/map2	Map Test 2
localhost:1234/map3	Hello from non-Map delegate.

When `Map` is used, the matched path segment(s) are removed from `HttpRequest.Path` and appended to `HttpRequest.PathBase` for each request.

`MapWhen` branches the request pipeline based on the result of the given predicate. Any predicate of type `Func<HttpContext, bool>` can be used to map requests to a new branch of the pipeline. In the following example, a predicate is used to detect the presence of a query string variable `branch`:

```

public class Startup
{
    private static void HandleBranch(IApplicationBuilder app)
    {
        app.Run(async context =>
        {
            var branchVer = context.Request.Query["branch"];
            await context.Response.WriteAsync($"Branch used = {branchVer}");
        });
    }

    public void Configure(IApplicationBuilder app)
    {
        app.MapWhen(context => context.Request.Query.ContainsKey("branch"),
                    HandleBranch);

        app.Run(async context =>
        {
            await context.Response.WriteAsync("Hello from non-Map delegate. <p>");
        });
    }
}

```

The following table shows the requests and responses from `http://localhost:1234` using the previous code:

REQUEST	RESPONSE
localhost:1234	Hello from non-Map delegate.
localhost:1234/?branch=master	Branch used = master

`Map` supports nesting, for example:

```

app.Map("/level1", level1App => {
    level1App.Map("/level2a", level2AApp => {
        // "/level1/level2a"
        //...
    });
    level1App.Map("/level2b", level2BApp => {
        // "/level1/level2b"
        //...
    });
});

```

`Map` can also match multiple segments at once, for example:

```
app.Map("/level1/level2", HandleMultiSeg);
```

## Built-in middleware

ASP.NET Core ships with the following middleware components, as well as a description of the order in which they should be added:

MIDDLEWARE	DESCRIPTION	ORDER
<a href="#">Authentication</a>	Provides authentication support.	Before <code>HttpContext.User</code> is needed. Terminal for OAuth callbacks.

MIDDLEWARE	DESCRIPTION	ORDER
<a href="#">CORS</a>	Configures Cross-Origin Resource Sharing.	Before components that use CORS.
<a href="#">Diagnostics</a>	Configures diagnostics.	Before components that generate errors.
<a href="#">Forwarded Headers</a>	Forwards proxied headers onto the current request.	Before components that consume the updated fields (examples: scheme, host, client IP, method).
<a href="#">HTTP Method Override</a>	Allows an incoming POST request to override the method.	Before components that consume the updated method.
<a href="#">HTTPS Redirection</a>	Redirect all HTTP requests to HTTPS (ASP.NET Core 2.1 or later).	Before components that consume the URL.
<a href="#">HTTP Strict Transport Security (HSTS)</a>	Security enhancement middleware that adds a special response header (ASP.NET Core 2.1 or later).	Before responses are sent and after components that modify requests (for example, Forwarded Headers, URL Rewriting).
<a href="#">Response Caching</a>	Provides support for caching responses.	Before components that require caching.
<a href="#">Response Compression</a>	Provides support for compressing responses.	Before components that require compression.
<a href="#">Request Localization</a>	Provides localization support.	Before localization sensitive components.
<a href="#">Routing</a>	Defines and constrains request routes.	Terminal for matching routes.
<a href="#">Session</a>	Provides support for managing user sessions.	Before components that require Session.
<a href="#">Static Files</a>	Provides support for serving static files and directory browsing.	Terminal if a request matches files.
<a href="#">URL Rewriting</a>	Provides support for rewriting URLs and redirecting requests.	Before components that consume the URL.
<a href="#">WebSockets</a>	Enables the WebSockets protocol.	Before components that are required to accept WebSocket requests.

## Writing middleware

Middleware is generally encapsulated in a class and exposed with an extension method. Consider the following middleware, which sets the culture for the current request from the query string:

```
public class Startup
{
    public void Configure(IApplicationBuilder app)
    {
        app.Use((context, next) =>
        {
            var cultureQuery = context.Request.Query["culture"];
            if (!string.IsNullOrWhiteSpace(cultureQuery))
            {
                var culture = new CultureInfo(cultureQuery);

                CultureInfo.CurrentCulture = culture;
                CultureInfo.CurrentUICulture = culture;
            }

            // Call the next delegate/middleware in the pipeline
            return next();
        });

        app.Run(async (context) =>
        {
            await context.Response.WriteAsync(
                $"Hello {CultureInfo.CurrentCulture.DisplayName}");
        });
    }
}
```

Note: The sample code above is used to demonstrate creating a middleware component. See [Globalization and localization](#) for ASP.NET Core's built-in localization support.

You can test the middleware by passing in the culture, for example `http://localhost:7997/?culture=no`.

The following code moves the middleware delegate to a class:

```

using Microsoft.AspNetCore.Http;
using System.Globalization;
using System.Threading.Tasks;

namespace Culture
{
    public class RequestCultureMiddleware
    {
        private readonly RequestDelegate _next;

        public RequestCultureMiddleware(RequestDelegate next)
        {
            _next = next;
        }

        public async Task InvokeAsync(HttpContext context)
        {
            var cultureQuery = context.Request.Query["culture"];
            if (!string.IsNullOrWhiteSpace(cultureQuery))
            {
                var culture = new CultureInfo(cultureQuery);

                CultureInfo.CurrentCulture = culture;
                CultureInfo.CurrentUICulture = culture;
            }

            // Call the next delegate/middleware in the pipeline
            await _next(context);
        }
    }
}

```

#### NOTE

In ASP.NET Core 1.x, the middleware `Task` method's name must be `Invoke`. In ASP.NET Core 2.0 or later, the name can be either `Invoke` or `InvokeAsync`.

The following extension method exposes the middleware through [IApplicationBuilder](#):

```

using Microsoft.AspNetCore.Builder;

namespace Culture
{
    public static class RequestCultureMiddlewareExtensions
    {
        public static IApplicationBuilder UseRequestCulture(
            this IApplicationBuilder builder)
        {
            return builder.UseMiddleware<RequestCultureMiddleware>();
        }
    }
}

```

The following code calls the middleware from `Configure`:

```

public class Startup
{
    public void Configure(IApplicationBuilder app)
    {
        app.UseRequestCulture();

        app.Run(async (context) =>
        {
            await context.Response.WriteAsync(
                $"Hello {CultureInfo.CurrentCulture.DisplayName}");
        });
    }
}

```

Middleware should follow the [Explicit Dependencies Principle](#) by exposing its dependencies in its constructor. Middleware is constructed once per *application lifetime*. See [Per-request dependencies](#) below if you need to share services with middleware within a request.

Middleware components can resolve their dependencies from dependency injection through constructor parameters. `UseMiddleware<T>` can also accept additional parameters directly.

### Per-request dependencies

Because middleware is constructed at app startup, not per-request, *scoped* lifetime services used by middleware constructors are not shared with other dependency-injected types during each request. If you must share a *scoped* service between your middleware and other types, add these services to the `Invoke` method's signature. The `Invoke` method can accept additional parameters that are populated by dependency injection. For example:

```

public class MyMiddleware
{
    private readonly RequestDelegate _next;

    public MyMiddleware(RequestDelegate next)
    {
        _next = next;
    }

    public async Task Invoke(HttpContext httpContext, IMyScopedService svc)
    {
        svc.MyProperty = 1000;
        await _next(httpContext);
    }
}

```

# ASP.NET Core Middleware

6/21/2018 • 9 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Steve Smith](#)

[View or download sample code \(how to download\)](#)

## What is middleware?

Middleware is software that's assembled into an application pipeline to handle requests and responses. Each component:

- Chooses whether to pass the request to the next component in the pipeline.
- Can perform work before and after the next component in the pipeline is invoked.

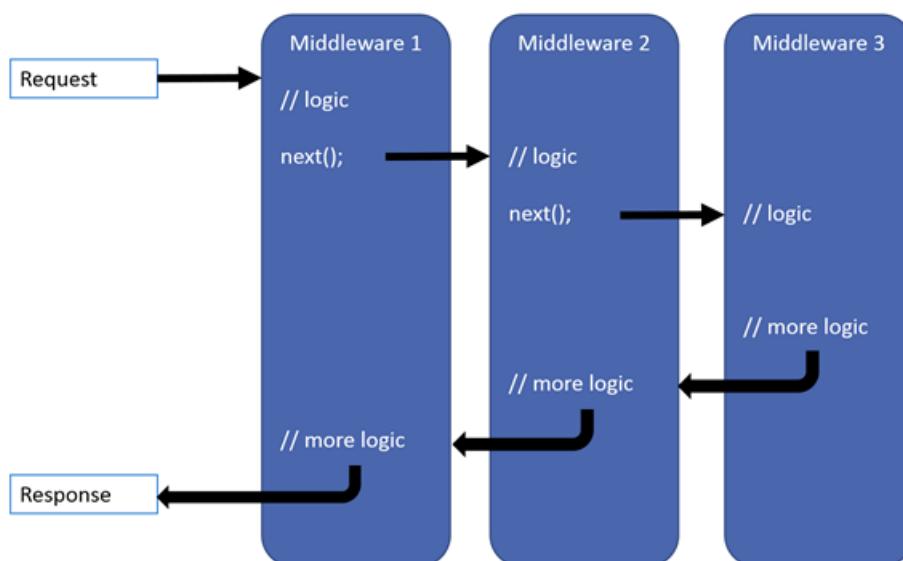

Request delegates are used to build the request pipeline. The request delegates handle each HTTP request.

Request delegates are configured using [Run](#), [Map](#), and [Use](#) extension methods. An individual request delegate can be specified in-line as an anonymous method (called in-line middleware), or it can be defined in a reusable class. These reusable classes and in-line anonymous methods are *middleware*, or *middleware components*. Each middleware component in the request pipeline is responsible for invoking the next component in the pipeline, or short-circuiting the chain if appropriate.

[Migrate HTTP Modules to Middleware](#) explains the difference between request pipelines in ASP.NET Core and ASP.NET 4.x and provides more middleware samples.

## Creating a middleware pipeline with `IApplicationBuilder`

The ASP.NET Core request pipeline consists of a sequence of request delegates, called one after the other, as this diagram shows (the thread of execution follows the black arrows):

Each delegate can perform operations before and after the next delegate. A delegate can also decide to not pass a request to the next delegate, which is called short-circuiting the request pipeline. Short-circuiting is often desirable because it avoids unnecessary work. For example, the static file middleware can return a request for a static file and short-circuit the rest of the pipeline. Exception-handling delegates need to be

called early in the pipeline, so they can catch exceptions that occur in later stages of the pipeline.

The simplest possible ASP.NET Core app sets up a single request delegate that handles all requests. This case doesn't include an actual request pipeline. Instead, a single anonymous function is called in response to every HTTP request.

```
using Microsoft.AspNetCore.Builder;
using Microsoft.AspNetCore.Hosting;
using Microsoft.AspNetCore.Http;

public class Startup
{
    public void Configure(IApplicationBuilder app)
    {
        app.Run(async context =>
        {
            await context.Response.WriteAsync("Hello, World!");
        });
    }
}
```

The first `app.Run` delegate terminates the pipeline.

You can chain multiple request delegates together with `app.Use`. The `next` parameter represents the next delegate in the pipeline. (Remember that you can short-circuit the pipeline by *not* calling the `next` parameter.) You can typically perform actions both before and after the next delegate, as this example demonstrates:

```
public class Startup
{
    public void Configure(IApplicationBuilder app)
    {
        app.Use(async (context, next) =>
        {
            // Do work that doesn't write to the Response.
            await next.Invoke();
            // Do logging or other work that doesn't write to the Response.
        });

        app.Run(async context =>
        {
            await context.Response.WriteAsync("Hello from 2nd delegate.");
        });
    }
}
```

#### WARNING

Don't call `next.Invoke` after the response has been sent to the client. Changes to `HttpResponse` after the response has started will throw an exception. For example, changes such as setting headers, status code, etc, will throw an exception. Writing to the response body after calling `next`:

- May cause a protocol violation. For example, writing more than the stated `content-length`.
- May corrupt the body format. For example, writing an HTML footer to a CSS file.

`HttpResponse.HasStarted` is a useful hint to indicate if headers have been sent and/or the body has been written to.

## Ordering

The order that middleware components are added in the `Configure` method defines the order in which

they're invoked on requests, and the reverse order for the response. This ordering is critical for security, performance, and functionality.

The Configure method (shown below) adds the following middleware components:

1. Exception/error handling

2. Static file server

3. Authentication

4. MVC

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

```
public void Configure(IApplicationBuilder app)
{
    app.UseExceptionHandler("/Home/Error"); // Call first to catch exceptions
                                                // thrown in the following middleware.

    app.UseStaticFiles();                      // Return static files and end pipeline.

    app.UseAuthentication();                  // Authenticate before you access
                                                // secure resources.

    app.UseMvcWithDefaultRoute();            // Add MVC to the request pipeline.
}
```

In the code above, `UseExceptionHandler` is the first middleware component added to the pipeline—therefore, it catches any exceptions that occur in later calls.

The static file middleware is called early in the pipeline so it can handle requests and short-circuit without going through the remaining components. The static file middleware provides **no** authorization checks. Any files served by it, including those under `wwwroot`, are publicly available. See [Static files](#) for an approach to secure static files.

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

If the request isn't handled by the static file middleware, it's passed on to the Identity middleware (`app.UseAuthentication`), which performs authentication. Identity doesn't short-circuit unauthenticated requests. Although Identity authenticates requests, authorization (and rejection) occurs only after MVC selects a specific Razor Page or controller and action.

The following example demonstrates a middleware ordering where requests for static files are handled by the static file middleware before the response compression middleware. Static files are not compressed with this ordering of the middleware. The MVC responses from `UseMvcWithDefaultRoute` can be compressed.

```
public void Configure(IApplicationBuilder app)
{
    app.UseStaticFiles();          // Static files not compressed
                                  // by middleware.

    app.UseResponseCompression();
    app.UseMvcWithDefaultRoute();
}
```

## Use, Run, and Map

You configure the HTTP pipeline using `use`, `Run`, and `Map`. The `use` method can short-circuit the pipeline (that is, if it doesn't call a `next` request delegate). `Run` is a convention, and some middleware components

may expose `Run[Middleware]` methods that run at the end of the pipeline.

`Map*` extensions are used as a convention for branching the pipeline. `Map` branches the request pipeline based on matches of the given request path. If the request path starts with the given path, the branch is executed.

```
public class Startup
{
    private static void HandleMapTest1(IApplicationBuilder app)
    {
        app.Run(async context =>
        {
            await context.Response.WriteAsync("Map Test 1");
        });
    }

    private static void HandleMapTest2(IApplicationBuilder app)
    {
        app.Run(async context =>
        {
            await context.Response.WriteAsync("Map Test 2");
        });
    }

    public void Configure(IApplicationBuilder app)
    {
        app.Map("/map1", HandleMapTest1);

        app.Map("/map2", HandleMapTest2);

        app.Run(async context =>
        {
            await context.Response.WriteAsync("Hello from non-Map delegate. <p>");
        });
    }
}
```

The following table shows the requests and responses from `http://localhost:1234` using the previous code:

REQUEST	RESPONSE
localhost:1234	Hello from non-Map delegate.
localhost:1234/map1	Map Test 1
localhost:1234/map2	Map Test 2
localhost:1234/map3	Hello from non-Map delegate.

When `Map` is used, the matched path segment(s) are removed from `HttpRequest.Path` and appended to `HttpRequest.PathBase` for each request.

`MapWhen` branches the request pipeline based on the result of the given predicate. Any predicate of type `Func<HttpContext, bool>` can be used to map requests to a new branch of the pipeline. In the following example, a predicate is used to detect the presence of a query string variable `branch`:

```

public class Startup
{
    private static void HandleBranch(IApplicationBuilder app)
    {
        app.Run(async context =>
        {
            var branchVer = context.Request.Query["branch"];
            await context.Response.WriteAsync($"Branch used = {branchVer}");
        });
    }

    public void Configure(IApplicationBuilder app)
    {
        app.MapWhen(context => context.Request.Query.ContainsKey("branch"),
                    HandleBranch);

        app.Run(async context =>
        {
            await context.Response.WriteAsync("Hello from non-Map delegate. <p>");
        });
    }
}

```

The following table shows the requests and responses from `http://localhost:1234` using the previous code:

REQUEST	RESPONSE
localhost:1234	Hello from non-Map delegate.
localhost:1234/?branch=master	Branch used = master

`Map` supports nesting, for example:

```

app.Map("/level1", level1App => {
    level1App.Map("/level2a", level2AApp => {
        // "/level1/level2a"
        //...
    });
    level1App.Map("/level2b", level2BApp => {
        // "/level1/level2b"
        //...
    });
});

```

`Map` can also match multiple segments at once, for example:

```
app.Map("/level1/level2", HandleMultiSeg);
```

## Built-in middleware

ASP.NET Core ships with the following middleware components, as well as a description of the order in which they should be added:

MIDDLEWARE	DESCRIPTION	ORDER
<a href="#">Authentication</a>	Provides authentication support.	Before <code>HttpContext.User</code> is needed. Terminal for OAuth callbacks.

MIDDLEWARE	DESCRIPTION	ORDER
CORS	Configures Cross-Origin Resource Sharing.	Before components that use CORS.
Diagnostics	Configures diagnostics.	Before components that generate errors.
Forwarded Headers	Forwards proxied headers onto the current request.	Before components that consume the updated fields (examples: scheme, host, client IP, method).
HTTP Method Override	Allows an incoming POST request to override the method.	Before components that consume the updated method.
HTTPS Redirection	Redirect all HTTP requests to HTTPS (ASP.NET Core 2.1 or later).	Before components that consume the URL.
HTTP Strict Transport Security (HSTS)	Security enhancement middleware that adds a special response header (ASP.NET Core 2.1 or later).	Before responses are sent and after components that modify requests (for example, Forwarded Headers, URL Rewriting).
Response Caching	Provides support for caching responses.	Before components that require caching.
Response Compression	Provides support for compressing responses.	Before components that require compression.
Request Localization	Provides localization support.	Before localization sensitive components.
Routing	Defines and constrains request routes.	Terminal for matching routes.
Session	Provides support for managing user sessions.	Before components that require Session.
Static Files	Provides support for serving static files and directory browsing.	Terminal if a request matches files.
URL Rewriting	Provides support for rewriting URLs and redirecting requests.	Before components that consume the URL.
WebSockets	Enables the WebSockets protocol.	Before components that are required to accept WebSocket requests.

## Writing middleware

Middleware is generally encapsulated in a class and exposed with an extension method. Consider the following middleware, which sets the culture for the current request from the query string:

```
public class Startup
{
    public void Configure(IApplicationBuilder app)
    {
        app.Use((context, next) =>
        {
            var cultureQuery = context.Request.Query["culture"];
            if (!string.IsNullOrWhiteSpace(cultureQuery))
            {
                var culture = new CultureInfo(cultureQuery);

                CultureInfo.CurrentCulture = culture;
                CultureInfo.CurrentUICulture = culture;
            }

            // Call the next delegate/middleware in the pipeline
            return next();
        });

        app.Run(async (context) =>
        {
            await context.Response.WriteAsync(
                $"Hello {CultureInfo.CurrentCulture.DisplayName}");
        });
    }
}
```

Note: The sample code above is used to demonstrate creating a middleware component. See [Globalization and localization](#) for ASP.NET Core's built-in localization support.

You can test the middleware by passing in the culture, for example `http://localhost:7997/?culture=no`.

The following code moves the middleware delegate to a class:

```

using Microsoft.AspNetCore.Http;
using System.Globalization;
using System.Threading.Tasks;

namespace Culture
{
    public class RequestCultureMiddleware
    {
        private readonly RequestDelegate _next;

        public RequestCultureMiddleware(RequestDelegate next)
        {
            _next = next;
        }

        public async Task InvokeAsync(HttpContext context)
        {
            var cultureQuery = context.Request.Query["culture"];
            if (!string.IsNullOrWhiteSpace(cultureQuery))
            {
                var culture = new CultureInfo(cultureQuery);

                CultureInfo.CurrentCulture = culture;
                CultureInfo.CurrentUICulture = culture;
            }

            // Call the next delegate/middleware in the pipeline
            await _next(context);
        }
    }
}

```

#### NOTE

In ASP.NET Core 1.x, the middleware `Task` method's name must be `Invoke`. In ASP.NET Core 2.0 or later, the name can be either `Invoke` or `InvokeAsync`.

The following extension method exposes the middleware through [IApplicationBuilder](#):

```

using Microsoft.AspNetCore.Builder;

namespace Culture
{
    public static class RequestCultureMiddlewareExtensions
    {
        public static IApplicationBuilder UseRequestCulture(
            this IApplicationBuilder builder)
        {
            return builder.UseMiddleware<RequestCultureMiddleware>();
        }
    }
}

```

The following code calls the middleware from `Configure`:

```

public class Startup
{
    public void Configure(IApplicationBuilder app)
    {
        app.UseRequestCulture();

        app.Run(async (context) =>
        {
            await context.Response.WriteAsync(
                $"Hello {CultureInfo.CurrentCulture.DisplayName}");
        });
    }
}

```

Middleware should follow the [Explicit Dependencies Principle](#) by exposing its dependencies in its constructor. Middleware is constructed once per *application lifetime*. See *Per-request dependencies* below if you need to share services with middleware within a request.

Middleware components can resolve their dependencies from dependency injection through constructor parameters. `UseMiddleware<T>` can also accept additional parameters directly.

### Per-request dependencies

Because middleware is constructed at app startup, not per-request, *scoped* lifetime services used by middleware constructors are not shared with other dependency-injected types during each request. If you must share a *scoped* service between your middleware and other types, add these services to the `Invoke` method's signature. The `Invoke` method can accept additional parameters that are populated by dependency injection. For example:

```

public class MyMiddleware
{
    private readonly RequestDelegate _next;

    public MyMiddleware(RequestDelegate next)
    {
        _next = next;
    }

    public async Task Invoke(HttpContext httpContext, IMyScopedService svc)
    {
        svc.MyProperty = 1000;
        await _next(httpContext);
    }
}

```

# Factory-based middleware activation in ASP.NET Core

6/21/2018 • 2 minutes to read • [Edit Online](#)

By [Luke Latham](#)

[IMiddlewareFactory](#)/[IMiddleware](#) is an extensibility point for [middleware](#) activation.

`UseMiddleware` extension methods check if a middleware's registered type implements `IMiddleware`. If it does, the `IMiddlewareFactory` instance registered in the container is used to resolve the `IMiddleware` implementation instead of using the convention-based middleware activation logic. The middleware is registered as a scoped or transient service in the app's service container.

Benefits:

- Activation per request (injection of scoped services)
- Strong typing of middleware

`IMiddleware` is activated per request, so scoped services can be injected into the middleware's constructor.

[View or download sample code](#) ([how to download](#))

The sample app demonstrates middleware activated by:

- Convention. For more information on conventional middleware activation, see the [Middleware](#) topic.
- An `IMiddleware` implementation. The default [MiddlewareFactory class](#) activates the middleware.

The middleware implementations function identically and record the value provided by a query string parameter (`key`). The middlewares use an injected database context (a scoped service) to record the query string value in an in-memory database.

## IMiddleware

[IMiddleware](#) defines middleware for the app's request pipeline. The `InvokeAsync(HttpContext, RequestDelegate)` method handles requests and returns a `Task` that represents the execution of the middleware.

Middleware activated by convention:

```

public class ConventionalMiddleware
{
    private readonly RequestDelegate _next;

    public ConventionalMiddleware(RequestDelegate next)
    {
        _next = next;
    }

    public async Task InvokeAsync(HttpContext context, AppDbContext db)
    {
        var keyValue = context.Request.Query["key"];

        if (!string.IsNullOrWhiteSpace(keyValue))
        {
            db.Add(new Request()
            {
                DT = DateTime.UtcNow,
                MiddlewareActivation = "ConventionalMiddleware",
                Value = keyValue
            });
        }

        await db.SaveChangesAsync();
    }

    await _next(context);
}

```

Middleware activated by `MiddlewareFactory` :

```

public class IMiddlewareMiddleware : IMiddleware
{
    private readonly AppDbContext _db;

    public IMiddlewareMiddleware(AppDbContext db)
    {
        _db = db;
    }

    public async Task InvokeAsync(HttpContext context, RequestDelegate next)
    {
        var keyValue = context.Request.Query["key"];

        if (!string.IsNullOrWhiteSpace(keyValue))
        {
            _db.Add(new Request()
            {
                DT = DateTime.UtcNow,
                MiddlewareActivation = "IMiddlewareMiddleware",
                Value = keyValue
            });
        }

        await _db.SaveChangesAsync();
    }

    await next(context);
}

```

Extensions are created for the middlewares:

```

public static class MiddlewareExtensions
{
    public static IApplicationBuilder UseConventionalMiddleware(
        this IApplicationBuilder builder)
    {
        return builder.UseMiddleware<ConventionalMiddleware>();
    }

    public static IApplicationBuilder UseIMiddlewareMiddleware(
        this IApplicationBuilder builder)
    {
        return builder.UseMiddleware<IMiddlewareMiddleware>();
    }
}

```

It isn't possible to pass objects to the factory-activated middleware with `UseMiddleware` :

```

public static IApplicationBuilder UseIMiddlewareMiddleware(
    this IApplicationBuilder builder, bool option)
{
    // Passing 'option' as an argument throws a NotSupportedException at runtime.
    return builder.UseMiddleware<IMiddlewareMiddleware>(option);
}

```

The factory-activated middleware is added to the built-in container in *Startup.cs*:

```

public void ConfigureServices(IServiceCollection services)
{
    services.Configure<CookiePolicyOptions>(options =>
    {
        options.CheckConsentNeeded = context => true;
        options.MinimumSameSitePolicy = SameSiteMode.None;
    });

    services.AddDbContext<AppDbContext>(options =>
        options.UseInMemoryDatabase("InMemoryDb"));

    services.AddTransient<IMiddlewareMiddleware>();

    services.AddMvc();
}

```

Both middlewares are registered in the request processing pipeline in `Configure` :

```
public void Configure(IApplicationBuilder app, IHostingEnvironment env)
{
    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
    }
    else
    {
        app.UseExceptionHandler("/Error");
        app.UseHsts();
    }

    app.UseConventionalMiddleware();
    app.UseIMiddlewareMiddleware();

    app.UseHttpsRedirection();
    app.UseStaticFiles();
    app.UseCookiePolicy();
    app.UseMvc();
}
```

## IMiddlewareFactory

[IMiddlewareFactory](#) provides methods to create middleware. The middleware factory implementation is registered in the container as a scoped service.

The default [IMiddlewareFactory](#) implementation, [MiddlewareFactory](#), is found in the [Microsoft.AspNetCore.Http](#) package ([reference source](#)).

## Additional resources

# Middleware activation with a third-party container in ASP.NET Core

6/21/2018 • 2 minutes to read • [Edit Online](#)

By [Luke Latham](#)

This article demonstrates how to use [IMiddlewareFactory](#) and [IMiddleware](#) as an extensibility point for [middleware](#) activation with a third-party container. For introductory information on [IMiddlewareFactory](#) and [IMiddleware](#), see the [Factory-based middleware activation](#) topic.

[View or download sample code \(how to download\)](#)

The sample app demonstrates middleware activation by an [IMiddlewareFactory](#) implementation, [SimpleInjectorMiddlewareFactory](#). The sample uses the [Simple Injector](#) dependency injection (DI) container.

The sample's middleware implementation records the value provided by a query string parameter ([key](#)). The middleware uses an injected database context (a scoped service) to record the query string value in an in-memory database.

## NOTE

The sample app uses [Simple Injector](#) purely for demonstration purposes. Use of Simple Injector isn't an endorsement. Middleware activation approaches described in the Simple Injector documentation and GitHub issues are recommended by the maintainers of Simple Injector. For more information, see the [Simple Injector documentation](#) and [Simple Injector GitHub repository](#).

## IMiddlewareFactory

[IMiddlewareFactory](#) provides methods to create middleware.

In the sample app, a middleware factory is implemented to create an [SimpleInjectorActivatedMiddleware](#) instance. The middleware factory uses the Simple Injector container to resolve the middleware:

```
public class SimpleInjectorMiddlewareFactory : IMiddlewareFactory
{
    private readonly Container _container;

    public SimpleInjectorMiddlewareFactory(Container container)
    {
        _container = container;
    }

    public IMiddleware Create(Type middlewareType)
    {
        return _container.GetInstance(middlewareType) as IMiddleware;
    }

    public void Release(IMiddleware middleware)
    {
        // The container is responsible for releasing resources.
    }
}
```

# IMiddleware

[IMiddleware](#) defines middleware for the app's request pipeline.

Middleware activated by an [IMiddlewareFactory](#) implementation

(*Middleware/SimpleInjectorActivatedMiddleware.cs*):

```
public class SimpleInjectorActivatedMiddleware : IMiddleware
{
    private readonly AppDbContext _db;

    public SimpleInjectorActivatedMiddleware(AppDbContext db)
    {
        _db = db;
    }

    public async Task InvokeAsync(HttpContext context, RequestDelegate next)
    {
        var keyValue = context.Request.Query["key"];

        if (!string.IsNullOrWhiteSpace(keyValue))
        {
            _db.Add(new Request()
            {
                DT = DateTime.UtcNow,
                MiddlewareActivation = "SimpleInjectorActivatedMiddleware",
                Value = keyValue
            });
            await _db.SaveChangesAsync();
        }

        await next(context);
    }
}
```

An extension is created for the middleware (*Middleware/MiddlewareExtensions.cs*):

```
public static class MiddlewareExtensions
{
    public static IApplicationBuilder UseSimpleInjectorActivatedMiddleware(
        this IApplicationBuilder builder)
    {
        return builder.UseMiddleware<SimpleInjectorActivatedMiddleware>();
    }
}
```

`Startup.ConfigureServices` must perform several tasks:

- Set up the Simple Injector container.
- Register the factory and middleware.
- Make the app's database context available from the Simple Injector container for a Razor Page.

```

public void ConfigureServices(IServiceCollection services)
{
    services.Configure<CookiePolicyOptions>(options =>
    {
        options.CheckConsentNeeded = context => true;
        options.MinimumSameSitePolicy = SameSiteMode.None;
    });

    services.AddMvc().SetCompatibilityVersion(CompatibilityVersion.Version_2_1);

    // Replace the default middleware factory with the
    // SimpleInjectorMiddlewareFactory.
    services.AddTransient<IMiddlewareFactory>(_ =>
    {
        return new SimpleInjectorMiddlewareFactory(_container);
    });

    // Wrap ASP.NET requests in a Simple Injector execution
    // context.
    services.UseSimpleInjectorAspNetRequestScoping(_container);

    // Provide the database context from the Simple
    // Injector container whenever it's requested from
    // the default service container.
    services.AddScoped<AppDbContext>(provider =>
        _container.GetInstance<AppDbContext>());

    _container.Options.DefaultScopedLifestyle = new AsyncScopedLifestyle();

    _container.Register<AppDbContext>(() =>
    {
        var optionsBuilder = new DbContextOptionsBuilder<DbContext>();
        optionsBuilder.UseInMemoryDatabase("InMemoryDb");
        return new AppDbContext(optionsBuilder.Options);
    }, Lifestyle.Scoped);

    _container.Register<SimpleInjectorActivatedMiddleware>();

    _container.Verify();
}

```

The middleware is registered in the request processing pipeline in `Startup.Configure` :

```

public void Configure(IApplicationBuilder app, IHostingEnvironment env)
{
    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
    }
    else
    {
        app.UseExceptionHandler("/Error");
        app.UseHsts();
    }

    app.UseSimpleInjectorActivatedMiddleware();

    app.UseHttpsRedirection();
    app.UseStaticFiles();
    app.UseCookiePolicy();
    app.UseMvc();
}

```

# Static files in ASP.NET Core

6/21/2018 • 8 minutes to read • [Edit Online](#)

By [Rick Anderson](#) and [Scott Addie](#)

Static files, such as HTML, CSS, images, and JavaScript, are assets an ASP.NET Core app serves directly to clients. Some configuration is required to enable serving of these files.

[View or download sample code \(how to download\)](#)

## Serve static files

Static files are stored within your project's web root directory. The default directory is `<content_root>/wwwroot`, but it can be changed via the [UseWebRoot](#) method. See [Content root](#) and [Web root](#) for more information.

The app's web host must be made aware of the content root directory.

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

The `WebHost.CreateDefaultBuilder` method sets the content root to the current directory:

```
public class Program
{
    public static void Main(string[] args)
    {
        BuildWebHost(args).Run();
    }

    public static IWebHost BuildWebHost(string[] args) =>
        WebHost.CreateDefaultBuilder(args)
            .UseStartup<Startup>()
            .Build();
}
```

Static files are accessible via a path relative to the web root. For example, the **Web Application** project template contains several folders within the `wwwroot` folder:

- **wwwroot**
  - **css**
  - **images**
  - **js**

The URI format to access a file in the `images` subfolder is `http://<server_address>/images/<image_file_name>`. For example, <http://localhost:9189/images/banner3.svg>.

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

If targeting .NET Framework, add the [Microsoft.AspNetCore.StaticFiles](#) package to your project. If targeting .NET Core, the [Microsoft.AspNetCore.All](#) metapackage includes this package.

Configure the [middleware](#) which enables the serving of static files.

## Serve files inside of web root

Invoke the [UseStaticFiles](#) method within `Startup.Configure`:

```
public void Configure(IApplicationBuilder app)
{
    app.UseStaticFiles();
}
```

The parameterless `UseStaticFiles` method overload marks the files in web root as servable. The following markup references `wwwroot/images/banner1.svg`:

```

```

## Serve files outside of web root

Consider a directory hierarchy in which the static files to be served reside outside of the web root:

- **wwwroot**
  - **css**
  - **images**
  - **js**
- **MyStaticFiles**
  - **images**
    - *banner1.svg*

A request can access the *banner1.svg* file by configuring the static file middleware as follows:

```
public void Configure(IApplicationBuilder app)
{
    app.UseStaticFiles(); // For the wwwroot folder

    app.UseStaticFiles(new StaticFileOptions
    {
        FileProvider = new PhysicalFileProvider(
            Path.Combine(Directory.GetCurrentDirectory(), "MyStaticFiles")),
        RequestPath = "/StaticFiles"
    });
}
```

In the preceding code, the *MyStaticFiles* directory hierarchy is exposed publicly via the *StaticFiles* URI segment. A request to `http://<server_address>/StaticFiles/images/banner1.svg` serves the *banner1.svg* file.

The following markup references *MyStaticFiles/images/banner1.svg*:

```

```

## Set HTTP response headers

A [StaticFileOptions](#) object can be used to set HTTP response headers. In addition to configuring static file serving from the web root, the following code sets the `Cache-Control` header:

```
public void Configure(IApplicationBuilder app)
{
    app.UseStaticFiles(new StaticFileOptions
    {
        OnPrepareResponse = ctx =>
        {
            // Requires the following import:
            // using Microsoft.AspNetCore.Http;
            ctx.Context.Response.Headers.Append("Cache-Control", "public,max-age=600");
        }
    });
}
```

The [HeaderDictionaryExtensions.Append](#) method exists in the [Microsoft.AspNetCore.Http](#) package.

The files have been made publicly cacheable for 10 minutes (600 seconds):

▼ Response Headers [view source](#)

Accept-Ranges: bytes  
Cache-Control: public,max-age=600  
Content-Length: 143058  
Content-Type: image/png  
Date: Wed, 01 Feb 2017 01:27:01 GMT  
ETag: "1d1909cf92bacd2"  
Last-Modified: Thu, 07 Apr 2016 07:13:24 GMT

## Static file authorization

The static file middleware doesn't provide authorization checks. Any files served by it, including those under `wwwroot`, are publicly accessible. To serve files based on authorization:

- Store them outside of `wwwroot` and any directory accessible to the static file middleware **and**
- Serve them via an action method to which authorization is applied. Return a [FileResult](#) object:

```
[Authorize]
public IActionResult BannerImage()
{
    var file = Path.Combine(Directory.GetCurrentDirectory(),
                           "MyStaticFiles", "images", "banner1.svg");

    return PhysicalFile(file, "image/svg+xml");
}
```

## Enable directory browsing

Directory browsing allows users of your web app to see a directory listing and files within a specified directory. Directory browsing is disabled by default for security reasons (see [Considerations](#)). Enable directory browsing by invoking the [UseDirectoryBrowser](#) method in `Startup.Configure`:

```

public void Configure(IApplicationBuilder app)
{
    app.UseStaticFiles(); // For the wwwroot folder

    app.UseStaticFiles(new StaticFileOptions
    {
        FileProvider = new PhysicalFileProvider(
            Path.Combine(Directory.GetCurrentDirectory(), "wwwroot", "images")),
        RequestPath = "/MyImages"
    });

    app.UseDirectoryBrowser(new DirectoryBrowserOptions
    {
        FileProvider = new PhysicalFileProvider(
            Path.Combine(Directory.GetCurrentDirectory(), "wwwroot", "images")),
        RequestPath = "/MyImages"
    });
}

```

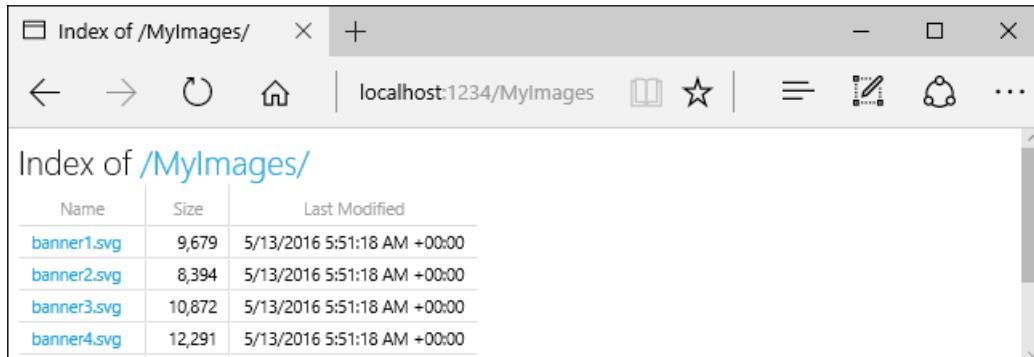

Add required services by invoking the [AddDirectoryBrowser](#) method from `Startup.ConfigureServices`:

```

public void ConfigureServices(IServiceCollection services)
{
    services.AddDirectoryBrowser();
}

```

The preceding code allows directory browsing of the `wwwroot/images` folder using the URL `http://<server_address>/MyImages`, with links to each file and folder:

See [Considerations](#) on the security risks when enabling browsing.

Note the two `UseStaticFiles` calls in the following example. The first call enables the serving of static files in the `wwwroot` folder. The second call enables directory browsing of the `wwwroot/images` folder using the URL `http://<server_address>/MyImages`:

```

public void Configure(IApplicationBuilder app)
{
    app.UseStaticFiles(); // For the wwwroot folder

    app.UseStaticFiles(new StaticFileOptions
    {
        FileProvider = new PhysicalFileProvider(
            Path.Combine(Directory.GetCurrentDirectory(), "wwwroot", "images")),
        RequestPath = "/MyImages"
    });

    app.UseDirectoryBrowser(new DirectoryBrowserOptions
    {
        FileProvider = new PhysicalFileProvider(
            Path.Combine(Directory.GetCurrentDirectory(), "wwwroot", "images")),
        RequestPath = "/MyImages"
    });
}

```

## Serve a default document

Setting a default home page provides visitors a logical starting point when visiting your site. To serve a default page without the user fully qualifying the URI, call the `UseDefaultFiles` method from `Startup.Configure`:

```

public void Configure(IApplicationBuilder app)
{
    app.UseDefaultFiles();
    app.UseStaticFiles();
}

```

### IMPORTANT

`UseDefaultFiles` must be called before `UseStaticFiles` to serve the default file. `UseDefaultFiles` is a URL rewriter that doesn't actually serve the file. Enable the static file middleware via `UseStaticFiles` to serve the file.

With `UseDefaultFiles`, requests to a folder search for:

- *default.htm*
- *default.html*
- *index.htm*
- *index.html*

The first file found from the list is served as though the request were the fully qualified URI. The browser URL continues to reflect the URI requested.

The following code changes the default file name to *mydefault.html*:

```

public void Configure(IApplicationBuilder app)
{
    // Serve my app-specific default file, if present.
    DefaultFilesOptions options = new DefaultFilesOptions();
    options.DefaultFileNames.Clear();
    options.DefaultFileNames.Add("mydefault.html");
    app.UseDefaultFiles(options);
    app.UseStaticFiles();
}

```

# UseFileServer

`UseFileServer` combines the functionality of `UseStaticFiles`, `UseDefaultFiles`, and `UseDirectoryBrowser`.

The following code enables the serving of static files and the default file. Directory browsing isn't enabled.

```
app.UseFileServer();
```

The following code builds upon the parameterless overload by enabling directory browsing:

```
app.UseFileServer(enableDirectoryBrowsing: true);
```

Consider the following directory hierarchy:

- **wwwroot**
  - **css**
  - **images**
  - **js**
- **MyStaticFiles**
  - **images**
    - *banner1.svg*
    - *default.html*

The following code enables static files, default files, and directory browsing of `MyStaticFiles`:

```
public void Configure(IApplicationBuilder app)
{
    app.UseStaticFiles(); // For the wwwroot folder

    app.UseFileServer(new FileServerOptions
    {
        FileProvider = new PhysicalFileProvider(
            Path.Combine(Directory.GetCurrentDirectory(), "MyStaticFiles")),
        RequestPath = "/StaticFiles",
        EnableDirectoryBrowsing = true
    });
}
```

`AddDirectoryBrowser` must be called when the `EnableDirectoryBrowsing` property value is `true`:

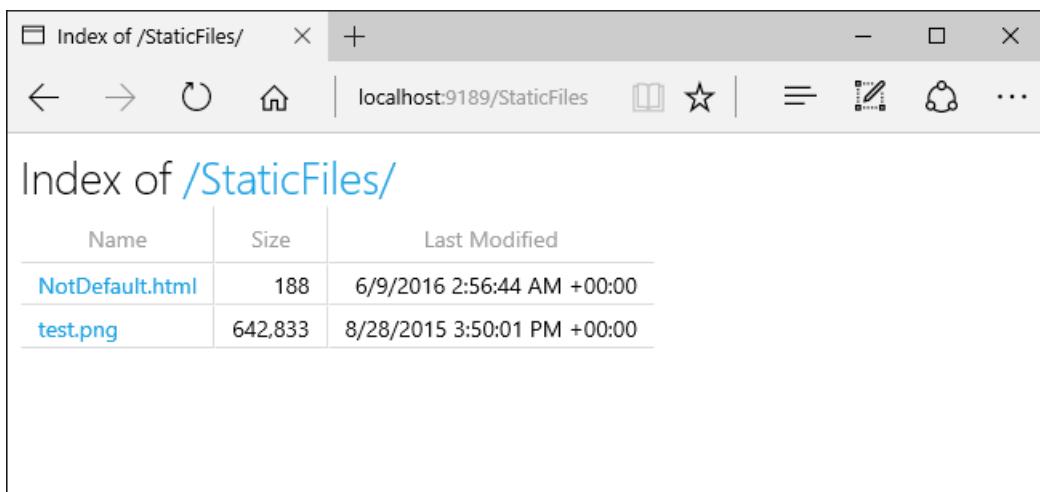

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddDirectoryBrowser();
}
```

Using the file hierarchy and preceding code, URLs resolve as follows:

URI	RESPONSE
<code>http://&lt;server_address&gt;/StaticFiles/images/banner1.svg</code>	MyStaticFiles/images/banner1.svg
<code>http://&lt;server_address&gt;/StaticFiles</code>	MyStaticFiles/default.html

If no default-named file exists in the `MyStaticFiles` directory, `http://<server_address>/StaticFiles` returns the

directory listing with clickable links:

**NOTE**

`UseDefaultFiles` and `UseDirectoryBrowser` use the URL `http://<server_address>/StaticFiles` without the trailing slash to trigger a client-side redirect to `http://<server_address>/StaticFiles/`. Notice the addition of the trailing slash. Relative URLs within the documents are deemed invalid without a trailing slash.

## FileExtensionContentTypeProvider

The `FileExtensionContentTypeProvider` class contains a `Mappings` property serving as a mapping of file extensions to MIME content types. In the following sample, several file extensions are registered to known MIME types. The `.rtf` extension is replaced, and `.mp4` is removed.

```
public void Configure(IApplicationBuilder app)
{
    // Set up custom content types - associating file extension to MIME type
    var provider = new FileExtensionContentTypeProvider();
    // Add new mappings
    provider.Mappings[".myapp"] = "application/x-msdownload";
    provider.Mappings[".htm3"] = "text/html";
    provider.Mappings[".image"] = "image/png";
    // Replace an existing mapping
    provider.Mappings[".rtf"] = "application/x-msdownload";
    // Remove MP4 videos.
    provider.Mappings.Remove(".mp4");

    app.UseStaticFiles(new StaticFileOptions
    {
        FileProvider = new PhysicalFileProvider(
            Path.Combine(Directory.GetCurrentDirectory(), "wwwroot", "images")),
        RequestPath = "/MyImages",
        ContentTypeProvider = provider
    });

    app.UseDirectoryBrowser(new DirectoryBrowserOptions
    {
        FileProvider = new PhysicalFileProvider(
            Path.Combine(Directory.GetCurrentDirectory(), "wwwroot", "images")),
        RequestPath = "/MyImages"
    });
}
```

See [MIME content types](#).

# Non-standard content types

The static file middleware understands almost 400 known file content types. If the user requests a file of an unknown file type, the static file middleware returns a HTTP 404 (Not Found) response. If directory browsing is enabled, a link to the file is displayed. The URI returns an HTTP 404 error.

The following code enables serving unknown types and renders the unknown file as an image:

```
public void Configure(IApplicationBuilder app)
{
    app.UseStaticFiles(new StaticFileOptions
    {
        ServeUnknownFileTypes = true,
        DefaultContentType = "image/png"
    });
}
```

With the preceding code, a request for a file with an unknown content type is returned as an image.

## WARNING

Enabling `ServeUnknownFileTypes` is a security risk. It's disabled by default, and its use is discouraged.

`FileExtensionContentTypeProvider` provides a safer alternative to serving files with non-standard extensions.

## Considerations

### WARNING

`UseDirectoryBrowser` and `UseStaticFiles` can leak secrets. Disabling directory browsing in production is highly recommended. Carefully review which directories are enabled via `UseStaticFiles` or `UseDirectoryBrowser`. The entire directory and its sub-directories become publicly accessible. Store files suitable for serving to the public in a dedicated directory, such as `<content_root>/wwwroot`. Separate these files from MVC views, Razor Pages (2.x only), configuration files, etc.

- The URLs for content exposed with `UseDirectoryBrowser` and `UseStaticFiles` are subject to the case sensitivity and character restrictions of the underlying file system. For example, Windows is case insensitive—macOS and Linux aren't.
- ASP.NET Core apps hosted in IIS use the [ASP.NET Core Module](#) to forward all requests to the app, including static file requests. The IIS static file handler isn't used. It has no chance to handle requests before they're handled by the module.
- Complete the following steps in IIS Manager to remove the IIS static file handler at the server or website level:
  1. Navigate to the **Modules** feature.
  2. Select **StaticFileModule** in the list.
  3. Click **Remove** in the **Actions** sidebar.

### WARNING

If the IIS static file handler is enabled **and** the ASP.NET Core Module is configured incorrectly, static files are served. This happens, for example, if the `web.config` file isn't deployed.

- Place code files (including `.cs` and `.cshtml`) outside of the app project's web root. A logical separation is

therefore created between the app's client-side content and server-based code. This prevents server-side code from being leaked.

# Routing in ASP.NET Core

6/22/2018 • 19 minutes to read • [Edit Online](#)

By [Ryan Nowak](#), [Steve Smith](#), and [Rick Anderson](#)

Routing functionality is responsible for mapping an incoming request to a route handler. Routes are defined in the ASP.NET app and configured when the app starts up. A route can optionally extract values from the URL contained in the request, and these values can then be used for request processing. Using route information from the ASP.NET app, the routing functionality is also able to generate URLs that map to route handlers. Therefore, routing can find a route handler based on a URL, or the URL corresponding to a given route handler based on route handler information.

## IMPORTANT

This document covers the low level ASP.NET Core routing. For ASP.NET Core MVC routing, see [Route to controller actions](#)

[View or download sample code \(how to download\)](#)

## Routing basics

Routing uses *routes* (implementations of [IRouter](#)) to:

- map incoming requests to *route handlers*
- generate URLs used in responses

Generally, an app has a single collection of routes. When a request arrives, the route collection is processed in order. The incoming request looks for a route that matches the request URL by calling the [RouteAsync](#) method on each available route in the route collection. By contrast, a response can use routing to generate URLs (for example, for redirection or links) based on route information, and thus avoid having to hard-code URLs, which helps maintainability.

Routing is connected to the [middleware](#) pipeline by the [RouterMiddleware](#) class. [ASP.NET Core MVC](#) adds routing to the middleware pipeline as part of its configuration. To learn about using routing as a standalone component, see [Using routing middleware](#).

## URL matching

URL matching is the process by which routing dispatches an incoming request to a *handler*. This process is generally based on data in the URL path, but can be extended to consider any data in the request. The ability to dispatch requests to separate handlers is key to scaling the size and complexity of an application.

Incoming requests enter the [RouterMiddleware](#), which calls the [RouteAsync](#) method on each route in sequence. The [IRouter](#) instance chooses whether to *handle* the request by setting the [RouteContext.Handler](#) to a non-null [RequestDelegate](#). If a route sets a handler for the request, route processing stops and the handler will be invoked to process the request. If all routes are tried and no handler is found for the request, the middleware calls *next* and the next middleware in the request pipeline is invoked.

The primary input to [RouteAsync](#) is the [RouteContext.HttpContext](#) associated with the current request. The [RouteContext.Handler](#) and [RouteContext.RouteData](#) are outputs that will be set after a route matches.

A match during [RouteAsync](#) will also set the properties of the [RouteContext.RouteData](#) to appropriate values based on the request processing done so far. If a route matches a request, the [RouteContext.RouteData](#) will

contain important state information about the *result*.

`RouteData.Values` is a dictionary of *route values* produced from the route. These values are usually determined by tokenizing the URL, and can be used to accept user input, or to make further dispatching decisions inside the application.

`RouteData.DataTokens` is a property bag of additional data related to the matched route. `DataTokens` are provided to support associating state data with each route so the application can make decisions later based on which route matched. These values are developer-defined and do **not** affect the behavior of routing in any way. Additionally, values stashed in data tokens can be of any type, in contrast to route values, which must be easily convertible to and from strings.

`RouteData.Routers` is a list of the routes that took part in successfully matching the request. Routes can be nested inside one another, and the `Routers` property reflects the path through the logical tree of routes that resulted in a match. Generally the first item in `Routers` is the route collection, and should be used for URL generation. The last item in `Routers` is the route handler that matched.

## URL generation

URL generation is the process by which routing can create a URL path based on a set of route values. This allows for a logical separation between your handlers and the URLs that access them.

URL generation follows a similar iterative process, but starts with user or framework code calling into the `GetVirtualPath` method of the route collection. Each *route* will then have its `GetVirtualPath` method called in sequence until a non-null `VirtualPathData` is returned.

The primary inputs to `GetVirtualPath` are:

- `VirtualPathContext.HttpContext`
- `VirtualPathContext.Values`
- `VirtualPathContext.AmbientValues`

Routes primarily use the route values provided by the `Values` and `AmbientValues` to decide where it's possible to generate a URL and what values to include. The `AmbientValues` are the set of route values that were produced from matching the current request with the routing system. In contrast, `Values` are the route values that specify how to generate the desired URL for the current operation. The `HttpContext` is provided in case a route needs to get services or additional data associated with the current context.

Tip: Think of `Values` as being a set of overrides for the `AmbientValues`. URL generation tries to reuse route values from the current request to make it easy to generate URLs for links using the same route or route values.

The output of `GetVirtualPath` is a `VirtualPathData`. `VirtualPathData` is a parallel of `RouteData`; it contains the `VirtualPath` for the output URL and some additional properties that should be set by the route.

The `VirtualPathData.VirtualPath` property contains the *virtual path* produced by the route. Depending on your needs you may need to process the path further. For instance, if you want to render the generated URL in HTML you need to prepend the base path of the application.

The `VirtualPathData.Router` is a reference to the route that successfully generated the URL.

The `VirtualPathData.DataTokens` properties is a dictionary of additional data related to the route that generated the URL. This is the parallel of `RouteData.DataTokens`.

## Creating routes

Routing provides the `Route` class as the standard implementation of `IRouter`. `Route` uses the *route template*

syntax to define patterns that will match against the URL path when `RouteAsync` is called. `Route` will use the same route template to generate a URL when `GetVirtualPath` is called.

Most applications will create routes by calling `MapRoute` or one of the similar extension methods defined on `IRouteBuilder`. All of these methods will create an instance of `Route` and add it to the route collection.

Note: `MapRoute` doesn't take a route handler parameter - it only adds routes that will be handled by the `DefaultHandler`. Since the default handler is an `IRouter`, it may decide not to handle the request. For example, ASP.NET MVC is typically configured as a default handler that only handles requests that match an available controller and action. To learn more about routing to MVC, see [Route to controller actions](#).

This is an example of a `MapRoute` call used by a typical ASP.NET MVC route definition:

```
routes.MapRoute(  
    name: "default",  
    template: "{controller=Home}/{action=Index}/{id?}");
```

This template will match a URL path like `/Products/Details/17` and extract the route values `{ controller = Products, action = Details, id = 17 }`. The route values are determined by splitting the URL path into segments, and matching each segment with the *route parameter* name in the route template. Route parameters are named. They're defined by enclosing the parameter name in braces `{ }`.

The template above could also match the URL path `/` and would produce the values `{ controller = Home, action = Index }`. This happens because the `{controller}` and `{action}` route parameters have default values, and the `id` route parameter is optional. An equals `=` sign followed by a value after the route parameter name defines a default value for the parameter. A question mark `?` after the route parameter name defines the parameter as optional. Route parameters with a default value *always* produce a route value when the route matches - optional parameters won't produce a route value if there was no corresponding URL path segment.

See [route-template-reference](#) for a thorough description of route template features and syntax.

This example includes a *route constraint*:

```
routes.MapRoute(  
    name: "default",  
    template: "{controller=Home}/{action=Index}/{id:int}");
```

This template will match a URL path like `/Products/Details/17`, but not `/Products/Details/Apples`. The route parameter definition `{id:int}` defines a *route constraint* for the `id` route parameter. Route constraints implement `IRouteConstraint` and inspect route values to verify them. In this example the route value `id` must be convertible to an integer. See [route-constraint-reference](#) for a more detailed explanation of route constraints that are provided by the framework.

Additional overloads of `MapRoute` accept values for `constraints`, `dataTokens`, and `defaults`. These additional parameters of `MapRoute` are defined as type `object`. The typical usage of these parameters is to pass an anonymously typed object, where the property names of the anonymous type match route parameter names.

The following two examples create equivalent routes:

```

routes.MapRoute(
    name: "default_route",
    template: "{controller}/{action}/{id?}",
    defaults: new { controller = "Home", action = "Index" });

routes.MapRoute(
    name: "default_route",
    template: "{controller=Home}/{action=Index}/{id?}");

```

Tip: The inline syntax for defining constraints and defaults can be more convenient for simple routes. However, there are features such as data tokens which are not supported by inline syntax.

This example demonstrates a few more features:

```

routes.MapRoute(
    name: "blog",
    template: "Blog/{*article}",
    defaults: new { controller = "Blog", action = "ReadArticle" });

```

This template will match a URL path like `/Blog/All-About-Routing/Introduction` and will extract the values `{ controller = Blog, action = ReadArticle, article = All-About-Routing/Introduction }`. The default route values for `controller` and `action` are produced by the route even though there are no corresponding route parameters in the template. Default values can be specified in the route template. The `article` route parameter is defined as a *catch-all* by the appearance of an asterisk `*` before the route parameter name. Catch-all route parameters capture the remainder of the URL path, and can also match the empty string.

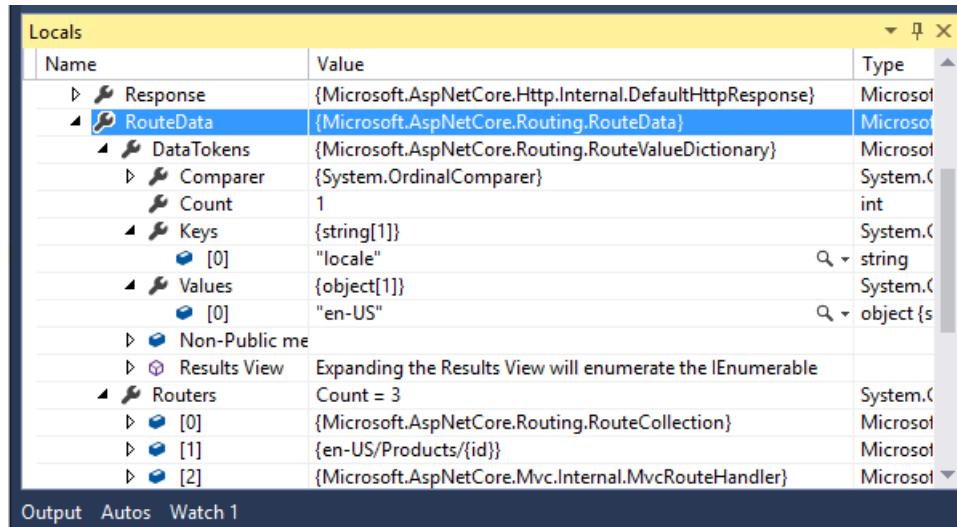

This example adds route constraints and data tokens:

```

routes.MapRoute(
    name: "us_english_products",
    template: "en-US/Products/{id}",
    defaults: new { controller = "Products", action = "Details" },
    constraints: new { id = new IntRouteConstraint() },
    dataTokens: new { locale = "en-US" });

```

This template matches a URL path like `/en-US/Products/5` and extracts the values `{ controller = Products, action = Details, id = 5 }` and the data tokens `{ locale = en-US }`.

## URL generation

The `Route` class can also perform URL generation by combining a set of route values with its route template. This is logically the reverse process of matching the URL path.

Tip: To better understand URL generation, imagine what URL you want to generate and then think about how a route template would match that URL. What values would be produced? This is the rough equivalent of how URL generation works in the `Route` class.

This example uses a basic ASP.NET MVC style route:

```
routes.MapRoute(  
    name: "default",  
    template: "{controller=Home}/{action=Index}/{id?}");
```

With the route values `{ controller = Products, action = List }`, this route will generate the URL `/Products/List`. The route values are substituted for the corresponding route parameters to form the URL path. Since `id` is an optional route parameter, it's no problem that it doesn't have a value.

With the route values `{ controller = Home, action = Index }`, this route will generate the URL `/`. The route values that were provided match the default values so the segments corresponding to those values can be safely omitted. Note that both URLs generated would round-trip with this route definition and produce the same route values that were used to generate the URL.

Tip: An app using ASP.NET MVC should use `UrlHelper` to generate URLs instead of calling into routing directly.

For more details about the URL generation process, see [url-generation-reference](#).

## Using Routing Middleware

Add the NuGet package "Microsoft.AspNetCore.Routing".

Add routing to the service container in `Startup.cs`:

```
public void ConfigureServices(IServiceCollection services)  
{  
    services.AddRouting();  
}
```

Routes must be configured in the `Configure` method in the `Startup` class. The sample below uses these APIs:

- `RouteBuilder`
- `Build`
- `MapGet` Matches only HTTP GET requests
- `UseRouter`

```

public void Configure(IApplicationBuilder app, ILoggerFactory loggerFactory)
{
    var trackPackageRouteHandler = new RouteHandler(context =>
    {
        var routeValues = context.GetRouteData().Values;
        return context.Response.WriteAsync(
            $"Hello! Route values: {string.Join(", ", routeValues)}");
    });

    var routeBuilder = new RouteBuilder(app, trackPackageRouteHandler);

    routeBuilder.MapRoute(
        "Track Package Route",
        "package/{operation:regex(^track|create|detonate)$}/{id:int}");

    routeBuilder.MapGet("hello/{name}", context =>
    {
        var name = context.GetRouteValue("name");
        // This is the route handler when HTTP GET "hello/<anything>" matches
        // To match HTTP GET "hello/<anything>/<anything>",
        // use routeBuilder.MapGet("hello/{*name}")
        return context.Response.WriteAsync($"Hi, {name}!");
    });

    var routes = routeBuilder.Build();
    app.UseRouter(routes);
}

```

The table below shows the responses with the given URIs.

URI	RESPONSE
/package/create/3	Hello! Route values: [operation, create], [id, 3]
/package/track/-3	Hello! Route values: [operation, track], [id, -3]
/package/track/-3/	Hello! Route values: [operation, track], [id, -3]
/package/track/	<Fall through, no match>
GET /hello/Joe	Hi, Joe!
POST /hello/Joe	<Fall through, matches HTTP GET only>
GET /hello/Joe/Smith	<Fall through, no match>

If you are configuring a single route, call `app.UseRouter` passing in an `IRouter` instance. You won't need to call `RouteBuilder`.

The framework provides a set of extension methods for creating routes such as:

- `MapRoute`
- `MapGet`
- `MapPost`
- `MapPut`
- `MapDelete`
- `MapVerb`

Some of these methods such as `MapGet` require a `RequestDelegate` to be provided. The `RequestDelegate` will be used as the *route handler* when the route matches. Other methods in this family allow configuring a middleware pipeline which will be used as the route handler. If the `Map` method doesn't accept a handler, such as `MapRoute`, then it will use the `DefaultHandler`.

The `Map[Verb]` methods use constraints to limit the route to the HTTP Verb in the method name. For example, see [MapGet](#) and [MapVerb](#).

## Route Template Reference

Tokens within curly braces (`{ }`) define *route parameters* which will be bound if the route is matched. You can define more than one route parameter in a route segment, but they must be separated by a literal value. For example `{controller=Home}{action=Index}` wouldn't be a valid route, since there's no literal value between `{controller}` and `{action}`. These route parameters must have a name, and may have additional attributes specified.

Literal text other than route parameters (for example, `{id}`) and the path separator `/` must match the text in the URL. Text matching is case-insensitive and based on the decoded representation of the URLs path. To match the literal route parameter delimiter `{` or `}`, escape it by repeating the character (`{}{}` or `{}{}`).

URL patterns that attempt to capture a filename with an optional file extension have additional considerations. For example, using the template `files/{filename}.{ext?}` - When both `filename` and `ext` exist, both values will be populated. If only `filename` exists in the URL, the route matches because the trailing period `.` is optional. The following URLs would match this route:

- `/files/myFile.txt`
- `/files/myFile`

You can use the `*` character as a prefix to a route parameter to bind to the rest of the URI - this is called a *catch-all* parameter. For example, `blog/{*slug}` would match any URI that started with `/blog` and had any value following it (which would be assigned to the `slug` route value). Catch-all parameters can also match the empty string.

Route parameters may have *default values*, designated by specifying the default after the parameter name, separated by an `=`. For example, `{controller=Home}` would define `Home` as the default value for `controller`. The default value is used if no value is present in the URL for the parameter. In addition to default values, route parameters may be optional (specified by appending a `?` to the end of the parameter name, as in `id?`). The difference between optional and "has default" is that a route parameter with a default value always produces a value; an optional parameter has a value only when one is provided.

Route parameters may also have constraints, which must match the route value bound from the URL. Adding a colon `:` and constraint name after the route parameter name specifies an *inline constraint* on a route parameter. If the constraint requires arguments those are provided enclosed in parentheses `( )` after the constraint name. Multiple inline constraints can be specified by appending another colon `:` and constraint name. The constraint name is passed to the `IInlineConstraintResolver` service to create an instance of `IRouteConstraint` to use in URL processing. For example, the route template `blog/{article:minlength(10)}` specifies the `minlength` constraint with the argument `10`. For more description route constraints, and a listing of the constraints provided by the framework, see [route-constraint-reference](#).

The following table demonstrates some route templates and their behavior.

ROUTE TEMPLATE	EXAMPLE MATCHING URL	NOTES
hello	/hello	Only matches the single path <code>/hello</code>

ROUTE TEMPLATE	EXAMPLE MATCHING URL	NOTES
{Page=Home}	/	Matches and sets <code>Page</code> to <code>Home</code>
{Page=Home}	/Contact	Matches and sets <code>Page</code> to <code>Contact</code>
{controller}/{action}/{id?}	/Products/List	Maps to <code>Products</code> controller and <code>List</code> action
{controller}/{action}/{id?}	/Products/Details/123	Maps to <code>Products</code> controller and <code>Details</code> action. <code>id</code> set to 123
{controller=Home}/{action=Index}/{id?}	/	Maps to <code>Home</code> controller and <code>Index</code> method; <code>id</code> is ignored.

Using a template is generally the simplest approach to routing. Constraints and defaults can also be specified outside the route template.

Tip: Enable [Logging](#) to see how the built in routing implementations, such as `Route`, match requests.

## Reserved routing names

The following keywords are reserved names and can't be used as route names or parameters:

- `action`
- `area`
- `controller`
- `handler`
- `page`

## Route constraint reference

Route constraints execute when a `Route` has matched the syntax of the incoming URL and tokenized the URL path into route values. Route constraints generally inspect the route value associated via the route template and make a simple yes/no decision about whether or not the value is acceptable. Some route constraints use data outside the route value to consider whether the request can be routed. For example, the `HttpMethodRouteConstraint` can accept or reject a request based on its HTTP verb.

### WARNING

Avoid using constraints for **input validation**, because doing so means that invalid input will result in a 404 (Not Found) instead of a 400 with an appropriate error message. Route constraints should be used to **disambiguate** between similar routes, not to validate the inputs for a particular route.

The following table demonstrates some route constraints and their expected behavior.

CONSTRAINT	EXAMPLE	EXAMPLE MATCHES	NOTES
<code>int</code>	<code>{id:int}</code>	<code>123456789</code> , <code>-123456789</code>	Matches any integer
<code>bool</code>	<code>{active:bool}</code>	<code>true</code> , <code>FALSE</code>	Matches <code>true</code> or <code>false</code> (case-insensitive)

CONSTRAINT	EXAMPLE	EXAMPLE MATCHES	NOTES
<code>datetime</code>	<code>{dob:datetime}</code>	<code>2016-12-31</code> , <code>2016-12-31 7:32pm</code>	Matches a valid <code>DateTime</code> value (in the invariant culture - see warning)
<code>decimal</code>	<code>{price:decimal}</code>	<code>49.99</code> , <code>-1,000.01</code>	Matches a valid <code>decimal</code> value (in the invariant culture - see warning)
<code>double</code>	<code>{weight:double}</code>	<code>1.234</code> , <code>-1,001.01e8</code>	Matches a valid <code>double</code> value (in the invariant culture - see warning)
<code>float</code>	<code>{weight:float}</code>	<code>1.234</code> , <code>-1,001.01e8</code>	Matches a valid <code>float</code> value (in the invariant culture - see warning)
<code>guid</code>	<code>{id:guid}</code>	<code>CD2C1638-1638-72D5-1638-DEADBEEF1638</code> , ,	Matches a valid <code>Guid</code> value
<code>long</code>	<code>{ticks:long}</code>	<code>123456789</code> , <code>-123456789</code>	Matches a valid <code>long</code> value
<code>minlength(value)</code>	<code>{username:minlength(4)}</code>	<code>Rick</code>	String must be at least 4 characters
<code>maxlength(value)</code>	<code>{filename:maxlength(8)}</code>	<code>Richard</code>	String must be no more than 8 characters
<code>length(length)</code>	<code>{filename:length(12)}</code>	<code>somefile.txt</code>	String must be exactly 12 characters long
<code>length(min,max)</code>	<code>{filename:length(8,16)}</code>	<code>somefile.txt</code>	String must be at least 8 and no more than 16 characters long
<code>min(value)</code>	<code>{age:min(18)}</code>	<code>19</code>	Integer value must be at least 18
<code>max(value)</code>	<code>{age:max(120)}</code>	<code>91</code>	Integer value must be no more than 120
<code>range(min,max)</code>	<code>{age:range(18,120)}</code>	<code>91</code>	Integer value must be at least 18 but no more than 120
<code>alpha</code>	<code>{name:alpha}</code>	<code>Rick</code>	String must consist of one or more alphabetical characters ( <code>a</code> - <code>z</code> , case-insensitive)

CONSTRAINT	EXAMPLE	EXAMPLE MATCHES	NOTES
<code>regex(expression)</code>	<code>{ssn:regex(^\\d{3}-\\d{2}-\\d{4}\$)}</code>	<code>123-45-6789</code>	String must match the regular expression (see tips about defining a regular expression)
<code>required</code>	<code>{name:required}</code>	<code>Rick</code>	Used to enforce that a non-parameter value is present during URL generation

### WARNING

Route constraints that verify the URL can be converted to a CLR type (such as `int` or `DateTime`) always use the invariant culture - they assume the URL is non-localizable. The framework-provided route constraints don't modify the values stored in route values. All route values parsed from the URL will be stored as strings. For example, the [Float route constraint](#) will attempt to convert the route value to a float, but the converted value is used only to verify it can be converted to a float.

## Regular expressions

The ASP.NET Core framework adds

`RegexOptions.IgnoreCase` | `RegexOptions.Compiled` | `RegexOptions.CultureInvariant` to the regular expression constructor. See [RegexOptions Enumeration](#) for a description of these members.

Regular expressions use delimiters and tokens similar to those used by Routing and the C# language. Regular expression tokens must be escaped. For example, to use the regular expression `^\\d{3}-\\d{2}-\\d{4}$` in Routing, it needs to have the `\` characters typed in as `\\` in the C# source file to escape the `\` string escape character (unless using [verbatim string literals](#)). The `{`, `}`, `'` and `'` characters need to be escaped by doubling them to escape the Routing parameter delimiter characters. The table below shows a regular expression and the escaped version.

EXPRESSION	NOTE
<code>^\\d{3}-\\d{2}-\\d{4}\$</code>	Regular expression
<code>^\\\\d{3}-\\\\d{2}-\\\\d{4}\$</code>	Escaped
<code>^[a-z]{2}\$</code>	Regular expression
<code>^[[a-z]]{{2}}\$</code>	Escaped

Regular expressions used in routing will often start with the `^` character (match starting position of the string) and end with the `$` character (match ending position of the string). The `^` and `$` characters ensure that the regular expression match the entire route parameter value. Without the `^` and `$` characters the regular expression will match any sub-string within the string, which is often not what you want. The table below shows some examples and explains why they match or fail to match.

EXPRESSION	STRING	MATCH	COMMENT
<code>[a-z]{2}</code>	<code>hello</code>	<code>yes</code>	substring matches

EXPRESSION	STRING	MATCH	COMMENT
[a-z]{2}	123abc456	yes	substring matches
[a-z]{2}	mz	yes	matches expression
[a-z]{2}	MZ	yes	not case sensitive
^[a-z]{2}\$	hello	no	see <code>^</code> and <code>\$</code> above
^[a-z]{2}\$	123abc456	no	see <code>^</code> and <code>\$</code> above

Refer to [.NET Framework Regular Expressions](#) for more information on regular expression syntax.

To constrain a parameter to a known set of possible values, use a regular expression. For example `{action:regex(^list|get|create)$)}` only matches the `action` route value to `list`, `get`, or `create`. If passed into the constraints dictionary, the string "`^(list|get|create)$`" would be equivalent. Constraints that are passed in the constraints dictionary (not inline within a template) that don't match one of the known constraints are also treated as regular expressions.

## URL Generation Reference

The example below shows how to generate a link to a route given a dictionary of route values and a `RouteCollection`.

```
app.Run(async (context) =>
{
    var dictionary = new RouteValueDictionary
    {
        { "operation", "create" },
        { "id", 123 }
    };

    var vpc = new VirtualPathContext(context, null, dictionary, "Track Package Route");
    var path = routes.GetVirtualPath(vpc).VirtualPath;

    context.Response.ContentType = "text/html";
    await context.Response.WriteAsync("Menu<hr/>");
    await context.Response.WriteAsync($"<a href='{path}'>Create Package 123</a><br/>");
});
```

The `VirtualPath` generated at the end of the sample above is `/package/create/123`.

The second parameter to the `VirtualPathContext` constructor is a collection of *ambient values*. Ambient values provide convenience by limiting the number of values a developer must specify within a certain request context. The current route values of the current request are considered ambient values for link generation. For example, in an ASP.NET MVC app if you are in the `About` action of the `HomeController`, you don't need to specify the controller route value to link to the `Index` action (the ambient value of `Home` will be used).

Ambient values that don't match a parameter are ignored, and ambient values are also ignored when an explicitly-provided value overrides it, going from left to right in the URL.

Values that are explicitly provided but which don't match anything are added to the query string. The following table shows the result when using the route template `{controller}/{action}/{id?}`.

AMBIENT VALUES	EXPLICIT VALUES	RESULT
controller="Home"	action="About"	/Home/About
controller="Home"	controller="Order",action="About"	/Order/About
controller="Home",color="Red"	action="About"	/Home/About
controller="Home"	action="About",color="Red"	/Home/About?color=Red

If a route has a default value that doesn't correspond to a parameter and that value is explicitly provided, it must match the default value. For example:

```
routes.MapRoute("blog_route", "blog/{*slug}",
    defaults: new { controller = "Blog", action = "ReadPost" });
```

Link generation would only generate a link for this route when the matching values for controller and action are provided.

# URL Rewriting Middleware in ASP.NET Core

6/21/2018 • 16 minutes to read • [Edit Online](#)

By [Luke Latham](#) and [Mikael Mengistu](#)

[View or download sample code](#) ([how to download](#))

URL rewriting is the act of modifying request URLs based on one or more predefined rules. URL rewriting creates an abstraction between resource locations and their addresses so that the locations and addresses are not tightly linked. There are several scenarios where URL rewriting is valuable:

- Moving or replacing server resources temporarily or permanently while maintaining stable locators for those resources.
- Splitting request processing across different apps or across areas of one app.
- Removing, adding, or reorganizing URL segments on incoming requests.
- Optimizing public URLs for Search Engine Optimization (SEO).
- Permitting the use of friendly public URLs to help people predict the content they will find by following a link.
- Redirecting insecure requests to secure endpoints.
- Preventing image hotlinking.

You can define rules for changing the URL in several ways, including Regex, Apache mod\_rewrite module rules, IIS Rewrite Module rules, and using custom rule logic. This document introduces URL rewriting with instructions on how to use URL Rewriting Middleware in ASP.NET Core apps.

## NOTE

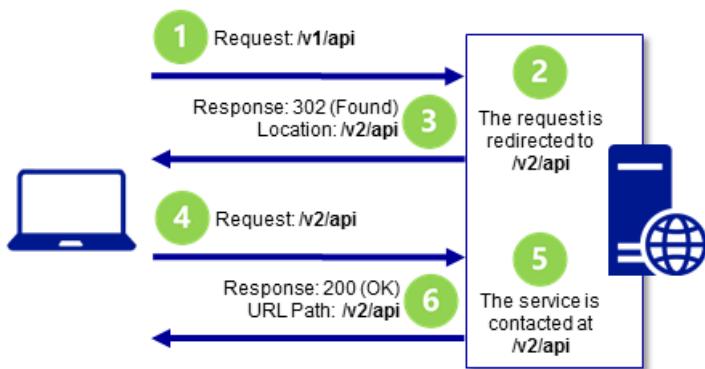

URL rewriting can reduce the performance of an app. Where feasible, you should limit the number and complexity of rules.

## URL redirect and URL rewrite

The difference in wording between *URL redirect* and *URL rewrite* may seem subtle at first but has important implications for providing resources to clients. ASP.NET Core's URL Rewriting Middleware is capable of meeting the need for both.

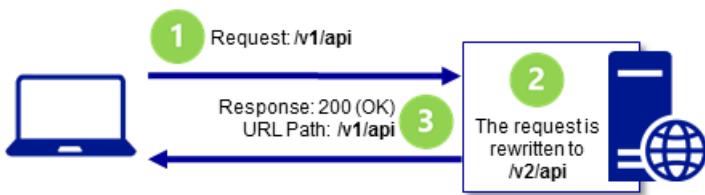

A *URL redirect* is a client-side operation, where the client is instructed to access a resource at another address. This requires a round-trip to the server. The redirect URL returned to the client appears in the browser's address bar when the client makes a new request for the resource.

If `/resource` is *redirected* to `/different-resource`, the client requests `/resource`. The server responds that the client should obtain the resource at `/different-resource` with a status code indicating that the redirect is either temporary or permanent. The client executes a new request for the resource at the redirect URL.

When redirecting requests to a different URL, you indicate whether the redirect is permanent or temporary. The 301 (Moved Permanently) status code is used where the resource has a new, permanent URL and you wish to instruct the client that all future requests for the resource should use the new URL. *The client may cache the response when a 301 status code is received.* The 302 (Found) status code is used where the redirection is temporary or generally subject to change, such that the client shouldn't store and reuse the redirect URL in the future. For more information, see [RFC 2616: Status Code Definitions](#).

A *URL rewrite* is a server-side operation to provide a resource from a different resource address. Rewriting a URL doesn't require a round-trip to the server. The rewritten URL isn't returned to the client and won't appear in the browser's address bar. When `/resource` is rewritten to `/different-resource`, the client requests `/resource`, and the server *internally* fetches the resource at `/different-resource`. Although the client might be able to retrieve the resource at the rewritten URL, the client won't be informed that the resource exists at the rewritten URL when it makes its request and receives the response.

## URL rewriting sample app

You can explore the features of the URL Rewriting Middleware with the [URL rewriting sample app](#). The app applies rewrite and redirect rules and shows the rewritten or redirected URL.

## When to use URL Rewriting Middleware

Use URL Rewriting Middleware when you are unable to use the [URL Rewrite module](#) with IIS on Windows Server, the [Apache mod\\_rewrite module](#) on Apache Server, [URL rewriting on Nginx](#), or your app is hosted on [HTTP.sys server](#) (formerly called [WebListener](#)). The main reasons to use the server-based URL rewriting technologies in IIS, Apache, or Nginx are that the middleware doesn't support the full features of these modules and the performance of the middleware probably won't match that of the modules. However, there are some features of the server modules that don't work with ASP.NET Core projects, such as the `IsFile` and `IsDirectory` constraints of the IIS Rewrite module. In these scenarios, use the middleware instead.

## Package

To include the middleware in your project, add a reference to the `Microsoft.AspNetCore.Rewrite` package. This feature is available for apps that target ASP.NET Core 1.1 or later.

## Extension and options

Establish your URL rewrite and redirect rules by creating an instance of the `RewriteOptions` class with extension

methods for each of your rules. Chain multiple rules in the order that you would like them processed. The `RewriteOptions` are passed into the URL Rewriting Middleware as it's added to the request pipeline with

```
app.UseRewriter(options);
```

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

```
public void Configure(IApplicationBuilder app)
{
    using (StreamReader apacheModRewriteStreamReader =
        File.OpenText("ApacheModRewrite.txt"))
    using (StreamReader iisUrlRewriteStreamReader =
        File.OpenText("IISUrlRewrite.xml"))
    {
        var options = new RewriteOptions()
            .AddRedirect("redirect-rule/(.*)", "redirected/$1")
            .AddRewrite(@"^rewrite-rule/(\d+)/(\d+)", "rewritten?var1=$1&var2=$2",
                skipRemainingRules: true)
            .AddApacheModRewrite(apacheModRewriteStreamReader)
            .AddIISUrlRewrite(iisUrlRewriteStreamReader)
            .Add(MethodRules.RedirectXMLRequests)
            .Add(new RedirectImageRequests(".png", "/png-images"))
            .Add(new RedirectImageRequests(".jpg", "/jpg-images"));

        app.UseRewriter(options);
    }

    app.Run(context => context.Response.WriteAsync(
        $"Rewritten or Redirected Url: " +
        $"{context.Request.Path + context.Request.QueryString}"));
}
```

## URL redirect

Use `AddRedirect` to redirect requests. The first parameter contains your regex for matching on the path of the incoming URL. The second parameter is the replacement string. The third parameter, if present, specifies the status code. If you don't specify the status code, it defaults to 302 (Found), which indicates that the resource is temporarily moved or replaced.

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

```

public void Configure(IApplicationBuilder app)
{
    using (StreamReader apacheModRewriteStreamReader =
        File.OpenText("ApacheModRewrite.txt"))
    using (StreamReader iisUrlRewriteStreamReader =
        File.OpenText("IISUrlRewrite.xml"))
    {
        var options = new RewriteOptions()
            .AddRedirect("redirect-rule/(.*)", "redirected/$1")
            .AddRewrite(@"^rewrite-rule/(\d+)/(\d+)", "rewritten?var1=$1&var2=$2",
                skipRemainingRules: true)
            .AddApacheModRewrite(apacheModRewriteStreamReader)
            .AddIISUrlRewrite(iisUrlRewriteStreamReader)
            .Add(MethodRules.RedirectXMLRequests)
            .Add(new RedirectImageRequests(".png", "/png-images"))
            .Add(new RedirectImageRequests(".jpg", "/jpg-images"));

        app.UseRewriter(options);
    }

    app.Run(context => context.Response.WriteAsync(
        $"Rewritten or Redirected Url: " +
        $"{context.Request.Path + context.Request.QueryString}"));
}

```

In a browser with developer tools enabled, make a request to the sample app with the path

`/redirect-rule/1234/5678`. The regex matches the request path on `redirect-rule/(.*)`, and the path is replaced with `/redirected/1234/5678`. The redirect URL is sent back to the client with a 302 (Found) status code. The browser makes a new request at the redirect URL, which appears in the browser's address bar. Since no rules in the sample app match on the redirect URL, the second request receives a 200 (OK) response from the app and the body of the response shows the redirect URL. A roundtrip is made to the server when a URL is *redirected*.

#### WARNING

Be cautious when establishing your redirect rules. Your redirect rules are evaluated on each request to the app, including after a redirect. It's easy to accidentally create a loop of infinite redirects.

Original Request: `/redirect-rule/1234/5678`

Name / Path	Protocol	Method	Result / Description
5678 http://localhost:5000/redirect-rule/1234/	HTTP	GET	302 Found
5678 http://localhost:5000/redirected/1234/	HTTP	GET	200 OK

The part of the expression contained within parentheses is called a *capture group*. The dot (`.`) of the expression means *match any character*. The asterisk (`*`) indicates *match the preceding character zero or more times*. Therefore, the last two path segments of the URL, `1234/5678`, are captured by capture group `(.*)`. Any value you provide in the request URL after `redirect-rule/` is captured by this single capture group.

In the replacement string, captured groups are injected into the string with the dollar sign (`$`) followed by the

sequence number of the capture. The first capture group value is obtained with `$1`, the second with `$2`, and they continue in sequence for the capture groups in your regex. There's only one captured group in the redirect rule regex in the sample app, so there's only one injected group in the replacement string, which is `$1`. When the rule is applied, the URL becomes `/redirected/1234/5678`.

## URL redirect to a secure endpoint

Use `AddRedirectToHttps` to redirect HTTP requests to the same host and path using HTTPS (`https://`). If the status code isn't supplied, the middleware defaults to 302 (Found). If the port isn't supplied, the middleware defaults to `null`, which means the protocol changes to `https://` and the client accesses the resource on port 443. The example shows how to set the status code to 301 (Moved Permanently) and change the port to 5001.

```
public void Configure(IApplicationBuilder app)
{
    var options = new RewriteOptions()
        .AddRedirectToHttps(301, 5001);

    app.UseRewriter(options);
}
```

Use `AddRedirectToHttpsPermanent` to redirect insecure requests to the same host and path with secure HTTPS protocol (`https://` on port 443). The middleware sets the status code to 301 (Moved Permanently).

```
public void Configure(IApplicationBuilder app)
{
    var options = new RewriteOptions()
        .AddRedirectToHttpsPermanent();

    app.UseRewriter(options);
}
```

### NOTE

When redirecting to HTTPS without the requirement for additional redirect rules, we recommend using HTTPS Redirection Middleware. For more information, see the [Enforce HTTPS](#) topic.

The sample app is capable of demonstrating how to use `AddRedirectToHttps` or `AddRedirectToHttpsPermanent`. Add the extension method to the `RewriteOptions`. Make an insecure request to the app at any URL. Dismiss the browser security warning that the self-signed certificate is untrusted or create an exception to trust the certificate.

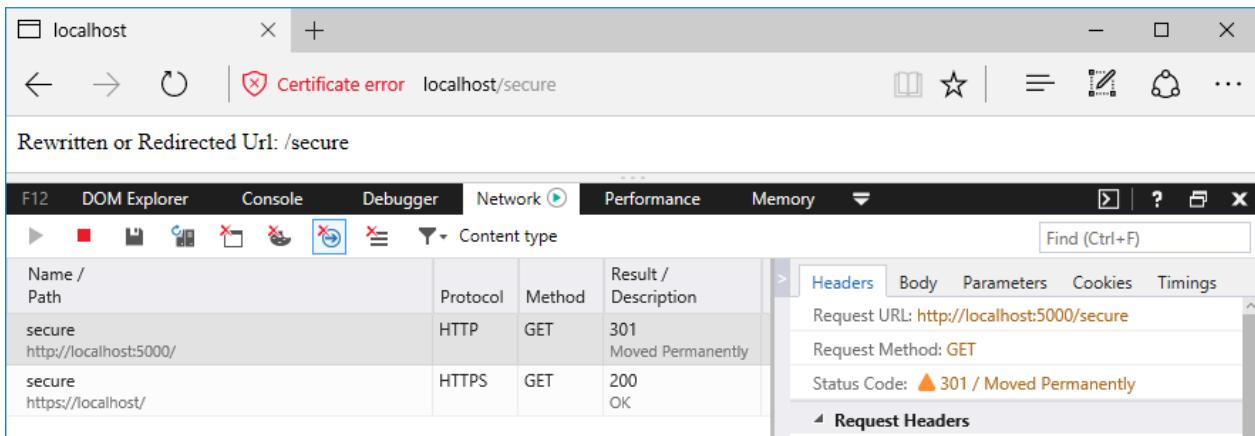

Original Request using `AddRedirectToHttps(301, 5001)` : `http://localhost:5000/secure`

The screenshot shows the Microsoft Edge DevTools Network tab. A request for `http://localhost:5000/secure` was made, resulting in a `301 Moved Permanently` response to `https://localhost:5001/secure`. The Headers section shows the following:

Name / Path	Protocol	Method	Result / Description
<code>secure</code> <code>http://localhost:5000/</code>	HTTP	GET	301 Moved Permanently
<code>secure</code> <code>https://localhost:5001/</code>	HTTPS	GET	200 OK

The Body section shows the response content: "Status Code: ▲ 301 / Moved Permanently".

Original Request using `AddRedirectToHttpsPermanent` : `http://localhost:5000/secure`

## URL rewrite

Use `AddRewrite` to create a rule for rewriting URLs. The first parameter contains your regex for matching on the incoming URL path. The second parameter is the replacement string. The third parameter, `skipRemainingRules: {true|false}`, indicates to the middleware whether or not to skip additional rewrite rules if the current rule is applied.

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

```
public void Configure(IApplicationBuilder app)
{
    using (StreamReader apacheModRewriteStreamReader =
        File.OpenText("ApacheModRewrite.txt"))
    using (StreamReader iisUrlRewriteStreamReader =
        File.OpenText("IISUrlRewrite.xml"))
    {
        var options = new RewriteOptions()
            .AddRedirect("redirect-rule/(.*)", "redirected/$1")
            .AddRewrite(@"^rewrite-rule/(\d+)/(\d+)", "rewritten?var1=$1&var2=$2",
                skipRemainingRules: true)
            .AddApacheModRewrite(apacheModRewriteStreamReader)
            .AddIISUrlRewrite(iisUrlRewriteStreamReader)
            .Add(MethodRules.RedirectXMLRequests)
            .Add(new RedirectImageRequests(".png", "/png-images"))
            .Add(new RedirectImageRequests(".jpg", "/jpg-images"));

        app.UseRewriter(options);
    }

    app.Run(context => context.Response.WriteAsync(
        $"Rewritten or Redirected Url: " +
        $"{context.Request.Path + context.Request.QueryString}"));
}
```

Original Request: `/rewrite-rule/1234/5678`

The screenshot shows the Microsoft Edge DevTools Network tab. The URL in the address bar is `localhost:5000/rewrite-rule/1234/5678`. The network table has one row with the following details:

Name / Path	Protocol	Method	Result / Description
<code>5678 http://localhost:5000/rewrite-rule/1234/</code>	HTTP	GET	200 OK

On the right side of the Network tab, the Headers section shows:

- Request URL: `http://localhost:5000/rewrite-rule/1234/...`
- Request Method: `GET`
- Status Code: `200 / OK`

The first thing you notice in the regex is the carat (^) at the beginning of the expression. This means that matching starts at the beginning of the URL path.

In the earlier example with the redirect rule, `redirect-rule/(.*)`, there's no carat at the start of the regex; therefore, any characters may precede `redirect-rule/` in the path for a successful match.

PATH	MATCH
<code>/redirect-rule/1234/5678</code>	Yes
<code>/my-cool-redirect-rule/1234/5678</code>	Yes
<code>/anotherredirect-rule/1234/5678</code>	Yes

The rewrite rule `^rewrite-rule/(\d+)/(\d+)` only matches paths if they start with `rewrite-rule/`. Notice the difference in matching between the rewrite rule below and the redirect rule above.

PATH	MATCH
<code>/rewrite-rule/1234/5678</code>	Yes
<code>/my-cool-rewrite-rule/1234/5678</code>	No
<code>/anotherrewrite-rule/1234/5678</code>	No

Following the `^rewrite-rule/` portion of the expression, there are two capture groups, `(\d+)/(\d+)`. The `\d` signifies *match a digit (number)*. The plus sign (+) means *match one or more of the preceding character*.

Therefore, the URL must contain a number followed by a forward-slash followed by another number. These capture groups are injected into the rewritten URL as `$1` and `$2`. The rewrite rule replacement string places the captured groups into the querystring. The requested path of `/rewrite-rule/1234/5678` is rewritten to obtain the resource at `/rewritten?var1=1234&var2=5678`. If a querystring is present on the original request, it's preserved when the URL is rewritten.

There's no roundtrip to the server to obtain the resource. If the resource exists, it's fetched and returned to the client with a 200 (OK) status code. Because the client isn't redirected, the URL in the browser address bar doesn't change. As far as the client is concerned, the URL rewrite operation never occurred.

## NOTE

Use `skipRemainingRules: true` whenever possible, because matching rules is an expensive process and reduces app response time. For the fastest app response:

- Order your rewrite rules from the most frequently matched rule to the least frequently matched rule.
- Skip the processing of the remaining rules when a match occurs and no additional rule processing is required.

## Apache mod\_rewrite

Apply Apache mod\_rewrite rules with `AddApacheModRewrite`. Make sure that the rules file is deployed with the app. For more information and examples of mod\_rewrite rules, see [Apache mod\\_rewrite](#).

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

A `StreamReader` is used to read the rules from the *ApacheModRewrite.txt* rules file.

```
public void Configure(IApplicationBuilder app)
{
    using (StreamReader apacheModRewriteStreamReader =
        File.OpenText("ApacheModRewrite.txt"))
    using (StreamReader iisUrlRewriteStreamReader =
        File.OpenText("IISUrlRewrite.xml"))
    {
        var options = new RewriteOptions()
            .AddRedirect("redirect-rule/(.*)", "redirected/$1")
            .AddRewrite(@"^rewrite-rule/(\d+)/(\d+)", "rewritten?var1=$1&var2=$2",
                skipRemainingRules: true)
            .AddApacheModRewrite(apacheModRewriteStreamReader)
            .AddIISUrlRewrite(iisUrlRewriteStreamReader)
            .Add(MethodRules.RedirectXMLRequests)
            .Add(new RedirectImageRequests(".png", "/png-images"))
            .Add(new RedirectImageRequests(".jpg", "/jpg-images"));

        app.UseRewriter(options);
    }

    app.Run(context => context.Response.WriteAsync(
        $"Rewritten or Redirected Url: " +
        $"{context.Request.Path + context.Request.QueryString}"));
}
```

The sample app redirects requests from `/apache-mod-rules-redirect/(.\\*)` to `/redirected?id=$1`. The response status code is 302 (Found).

```
# Rewrite path with additional sub directory
RewriteRule ^/apache-mod-rules-redirect/(.*) /redirected?id=$1 [L,R=302]
```

Original Request: `/apache-mod-rules-redirect/1234`

The screenshot shows the Microsoft Edge DevTools Network tab. The URL in the address bar is `localhost:5000/redirected?id=1234`. The network table shows two entries:

Name / Path	Protocol	Method	Result / Description
1234 <code>http://localhost:5000/apache-mod-rules-redirect/</code>	HTTP	GET	302 Found
redirected?id=1234 <code>http://localhost:5000/</code>	HTTP	GET	200 OK

The Headers panel shows the following details:

- Request URL: `http://localhost:5000/apache-mod-rules...`
- Request Method: `GET`
- Status Code: `302 / Found`

#### Supported server variables

The middleware supports the following Apache mod\_rewrite server variables:

- `CONN_REMOTE_ADDR`
- `HTTP_ACCEPT`
- `HTTP_CONNECTION`
- `HTTP_COOKIE`
- `HTTP_FORWARDED`
- `HTTP_HOST`
- `HTTP_REFERER`
- `HTTP_USER_AGENT`
- `HTTPS`
- `IPV6`
- `QUERY_STRING`
- `REMOTE_ADDR`
- `REMOTE_PORT`
- `REQUEST_FILENAME`
- `REQUEST_METHOD`
- `REQUEST_SCHEME`
- `REQUEST_URI`
- `SCRIPT_FILENAME`
- `SERVER_ADDR`
- `SERVER_PORT`
- `SERVER_PROTOCOL`
- `TIME`
- `TIME_DAY`
- `TIME_HOUR`
- `TIME_MIN`
- `TIME_MON`
- `TIME_SEC`
- `TIME_WDAY`
- `TIME_YEAR`

#### IIS URL Rewrite Module rules

To use rules that apply to the IIS URL Rewrite Module, use `AddIISUrlRewrite`. Make sure that the rules file is deployed with the app. Don't direct the middleware to use your `web.config` file when running on Windows Server IIS. With IIS, these rules should be stored outside of your `web.config` to avoid conflicts with the IIS Rewrite module. For more information and examples of IIS URL Rewrite Module rules, see [Using Url Rewrite Module 2.0](#)

and [URL Rewrite Module Configuration Reference](#).

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

A `StreamReader` is used to read the rules from the `IISUrlRewrite.xml` rules file.

```
public void Configure(IApplicationBuilder app)
{
    using (StreamReader apacheModRewriteStreamReader =
        File.OpenText("ApacheModRewrite.txt"))
    using (StreamReader iisUrlRewriteStreamReader =
        File.OpenText("IISUrlRewrite.xml"))
    {
        var options = new RewriteOptions()
            .AddRedirect("redirect-rule/(.*)", "redirected/$1")
            .AddRewrite(@"^rewrite-rule/(\d+)/(\d+)", "rewritten?var1=$1&var2=$2",
                skipRemainingRules: true)
            .AddApacheModRewrite(apacheModRewriteStreamReader)
            .AddIISUrlRewrite(iisUrlRewriteStreamReader)
            .Add(MethodRules.RedirectXMLRequests)
            .Add(new RedirectImageRequests(".png", "/png-images"))
            .Add(new RedirectImageRequests(".jpg", "/jpg-images"));

        app.UseRewriter(options);
    }

    app.Run(context => context.Response.WriteAsync(
        $"Rewritten or Redirected Url: " +
        $"{context.Request.Path + context.Request.QueryString}"));
}
```

The sample app rewrites requests from `/iis-rules-rewrite/(.*)` to `/rewritten?id=$1`. The response is sent to the client with a 200 (OK) status code.

```
<rewrite>
<rules>
    <rule name="Rewrite segment to id querystring" stopProcessing="true">
        <match url="^iis-rules-rewrite/(.*)$" />
        <action type="Rewrite" url="rewritten?id={R:1}" appendQueryString="false"/>
    </rule>
</rules>
</rewrite>
```

Original Request: `/iis-rules-rewrite/1234`

The screenshot shows the Microsoft Edge DevTools Network tab. The request URL is `localhost:5000/iis-rules-rewrite/1234`. The response status is `Rewritten or Redirected Url: /rewritten?id=1234`. The Network tab details table shows the following:

Name / Path	Protocol	Method	Result / Description
1234 http://localhost:5000/iis-rules-rewrite/	HTTP	GET	200 OK

The Headers section shows the following:

- Request URL: `http://localhost:5000/iis-rules-rewrite/1234`
- Request Method: `GET`
- Status Code: `200 / OK`

If you have an active IIS Rewrite Module with server-level rules configured that would impact your app in

undesirable ways, you can disable the IIS Rewrite Module for an app. For more information, see [Disabling IIS modules](#).

#### Unsupported features

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

The middleware released with ASP.NET Core 2.x doesn't support the following IIS URL Rewrite Module features:

- Outbound Rules
- Custom Server Variables
- Wildcards
- LogRewrittenUrl

#### Supported server variables

The middleware supports the following IIS URL Rewrite Module server variables:

- CONTENT\_LENGTH
- CONTENT\_TYPE
- HTTP\_ACCEPT
- HTTP\_CONNECTION
- HTTP\_COOKIE
- HTTP\_HOST
- HTTP\_REFERER
- HTTP\_URL
- HTTP\_USER\_AGENT
- HTTPS
- LOCAL\_ADDR
- QUERY\_STRING
- REMOTE\_ADDR
- REMOTE\_PORT
- REQUEST\_FILENAME
- REQUEST\_URI

#### NOTE

You can also obtain an `IFileProvider` via a `PhysicalFileProvider`. This approach may provide greater flexibility for the location of your rewrite rules files. Make sure that your rewrite rules files are deployed to the server at the path you provide.

```
PhysicalFileProvider fileProvider = new PhysicalFileProvider(Directory.GetCurrentDirectory());
```

#### Method-based rule

Use `Add(Action<RewriteContext> applyRule)` to implement your own rule logic in a method. The `RewriteContext` exposes the `HttpContext` for use in your method. The `context.Result` determines how additional pipeline processing is handled.

CONTEXT.RESULT	ACTION
<code>RuleResult.ContinueRules</code> (default)	Continue applying rules

CONTEXT.RESULT	ACTION
RuleResult.EndResponse	Stop applying rules and send the response
RuleResult.SkipRemainingRules	Stop applying rules and send the context to the next middleware

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

```
public void Configure(IApplicationBuilder app)
{
    using (StreamReader apacheModRewriteStreamReader =
        File.OpenText("ApacheModRewrite.txt"))
    using (StreamReader iisUrlRewriteStreamReader =
        File.OpenText("IISUrlRewrite.xml"))
    {
        var options = new RewriteOptions()
            .AddRedirect("redirect-rule/(.*)", "redirected/$1")
            .AddRewrite(@"^rewrite-rule/(\d+)(\d+)", "rewritten?var1=$1&var2=$2",
                skipRemainingRules: true)
            .AddApacheModRewrite(apacheModRewriteStreamReader)
            .AddIISUrlRewrite(iisUrlRewriteStreamReader)
            .Add(MethodRules.RedirectXMLRequests)
            .Add(new RedirectImageRequests(".png", "/png-images"))
            .Add(new RedirectImageRequests(".jpg", "/jpg-images"));

        app.UseRewriter(options);
    }

    app.Run(context => context.Response.WriteAsync(
        $"Rewritten or Redirected Url: " +
        $"{context.Request.Path + context.Request.QueryString}"));
}
```

The sample app demonstrates a method that redirects requests for paths that end with `.xml`. If you make a request for `/file.xml`, it's redirected to `/xmlfiles/file.xml`. The status code is set to 301 (Moved Permanently). For a redirect, you must explicitly set the status code of the response; otherwise, a 200 (OK) status code is returned and the redirect won't occur on the client.

```
public static void RedirectXMLRequests(RewriteContext context)
{
    var request = context.HttpContext.Request;

    // Because we're redirecting back to the same app, stop
    // processing if the request has already been redirected
    if (request.Path.StartsWithSegments(new PathString("/xmlfiles")))
    {
        return;
    }

    if (request.Path.Value.EndsWith(".xml", StringComparison.OrdinalIgnoreCase))
    {
        var response = context.HttpContext.Response;
        response.StatusCode = StatusCodes.Status301MovedPermanently;
        context.Result = RuleResult.EndResponse;
        response.Headers[HeaderNames.Location] =
            "/xmlfiles" + request.Path + request.QueryString;
    }
}
```

Original Request: /file.xml

The screenshot shows the Network tab of the F12 developer tools. It lists two requests: one for 'file.xml' at 'http://localhost:5000/' with a 301 status code and another for 'file.xml' at 'http://localhost:5000/xmlfiles/'. The status bar indicates the redirected URL is 'localhost:5000/xmlfiles/file.xml'. The Headers section shows the response includes 'Status Code: ▲ 301 / Moved Permanently'.

## IRule-based rule

Use `Add(IRule)` to implement your own rule logic in a class that derives from `IRule`. Using an `IRule` provides greater flexibility over using the method-based rule approach. Your derived class may include a constructor, where you can pass in parameters for the `ApplyRule` method.

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

```
public void Configure(IApplicationBuilder app)
{
    using (StreamReader apacheModRewriteStreamReader =
        File.OpenText("ApacheModRewrite.txt"))
    using (StreamReader iisUrlRewriteStreamReader =
        File.OpenText("IISUrlRewrite.xml"))
    {
        var options = new RewriteOptions()
            .AddRedirect("redirect-rule/(.*)", "redirected/$1")
            .AddRewrite(@"^rewrite-rule/(\d+)/(d+)", "rewritten?var1=$1&var2=$2",
                skipRemainingRules: true)
            .AddApacheModRewrite(apacheModRewriteStreamReader)
            .AddIISUrlRewrite(iisUrlRewriteStreamReader)
            .Add(MethodRules.RedirectXMLRequests)
            .Add(new RedirectImageRequests(".png", "/png-images"))
            .Add(new RedirectImageRequests(".jpg", "/jpg-images"));

        app.UseRewriter(options);
    }

    app.Run(context => context.Response.WriteAsync(
        $"Rewritten or Redirected Url: " +
        $"{context.Request.Path + context.Request.QueryString}"));
}
```

The values of the parameters in the sample app for the `extension` and the `newPath` are checked to meet several conditions. The `extension` must contain a value, and the value must be `.png`, `.jpg`, or `.gif`. If the `newPath` isn't valid, an `ArgumentException` is thrown. If you make a request for `image.png`, it's redirected to `/png-images/image.png`. If you make a request for `image.jpg`, it's redirected to `/jpg-images/image.jpg`. The status code is set to 301 (Moved Permanently), and the `context.Result` is set to stop processing rules and send the response.

```

public class RedirectImageRequests : IRule
{
    private readonly string _extension;
    private readonly PathString _newPath;

    public RedirectImageRequests(string extension, string newPath)
    {
        if (string.IsNullOrEmpty(extension))
        {
            throw new ArgumentException(nameof(extension));
        }

        if (!Regex.IsMatch(extension, @"^\.png|jpg|gif$"))
        {
            throw new ArgumentException("Invalid extension", nameof(extension));
        }

        if (!Regex.IsMatch(newPath, @"^/[A-Za-z0-9]+"))
        {
            throw new ArgumentException("Invalid path", nameof(newPath));
        }

        _extension = extension;
        _newPath = new PathString(newPath);
    }

    public void ApplyRule(RewriteContext context)
    {
        var request = context.HttpContext.Request;

        // Because we're redirecting back to the same app, stop
        // processing if the request has already been redirected
        if (request.Path.StartsWithSegments(_newPath))
        {
            return;
        }

        if (request.Path.Value.EndsWith(_extension, StringComparison.OrdinalIgnoreCase))
        {
            var response = context.HttpContext.Response;
            response.StatusCode = StatusCodes.Status301MovedPermanently;
            context.Result = RuleResult.EndResponse;
            response.Headers[HeaderNames.Location] =
                _newPath + request.Path + request.QueryString;
        }
    }
}

```

Original Request: /image.png

The screenshot shows a browser window with the address bar containing "localhost:5000/png-images/image.png". Below the address bar, the status bar displays "Rewritten or Redirected Url: /png-images/image.png". The browser interface includes standard navigation buttons (back, forward, search) and a toolbar with various icons.

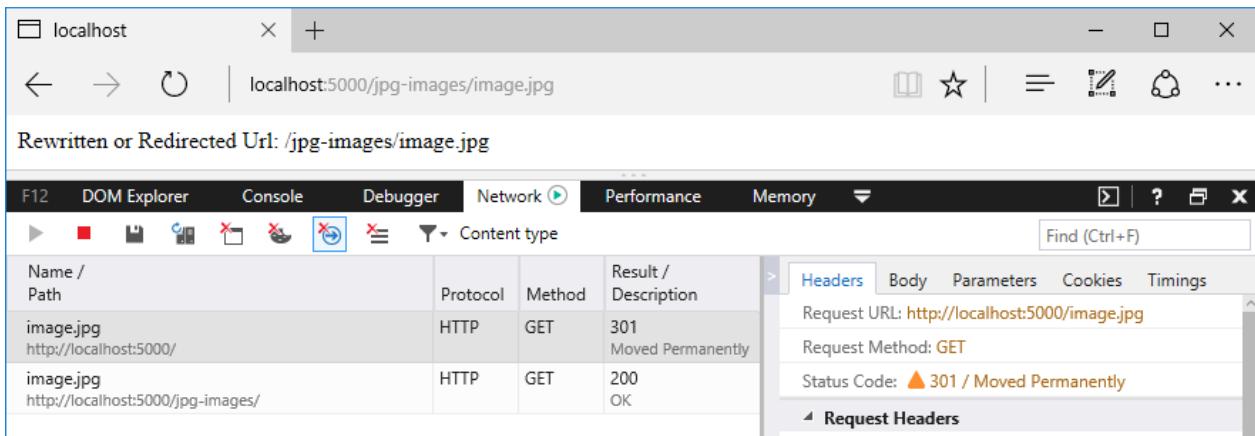

The Network tab of the developer tools is selected, showing the following table:

Name / Path	Protocol	Method	Result / Description
image.png http://localhost:5000/	HTTP	GET	301 Moved Permanently
image.png http://localhost:5000/png-images/	HTTP	GET	200 OK

Details pane on the right side of the developer tools shows the following information:

- Request URL: <http://localhost:5000/image.png>
- Request Method: GET
- Status Code: ▲ 301 / Moved Permanently
- Request Headers (partial list):

Original Request: /image.jpg

## Regex examples

GOAL	REGEX STRING & MATCH EXAMPLE	REPLACEMENT STRING & OUTPUT EXAMPLE
Rewrite path into querystring	<code>^path/(.*)/(.*)</code> <code>/path/abc/123</code>	<code>path?var1=\$1&amp;var2=\$2</code> <code>/path?var1=abc&amp;var2=123</code>
Strip trailing slash	<code>(.*)/\$</code> <code>/path/</code>	<code>\$1</code> <code>/path</code>
Enforce trailing slash	<code>(.*[^/])\$</code> <code>/path</code>	<code>\$1/</code> <code>/path/</code>
Avoid rewriting specific requests	<code>^(.*)(?&lt;!\.axd)\$</code> or <code>^(?!.*\.axd\$)(.*)\$</code> Yes: <code>/resource.htm</code> No: <code>/resource.axd</code>	<code>rewritten/\$1</code> <code>/rewritten/resource.htm</code> <code>/resource.axd</code>
Rearrange URL segments	<code>path/(.*)/(.*)/(.*)</code> <code>path/1/2/3</code>	<code>path/\$3/\$2/\$1</code> <code>path/3/2/1</code>
Replace a URL segment	<code>^(.*)/segment2/(.*)</code> <code>/segment1/segment2/segment3</code>	<code>\$1/replaced/\$2</code> <code>/segment1/replaced/segment3</code>

# Use multiple environments in ASP.NET Core

7/11/2018 • 8 minutes to read • [Edit Online](#)

By [Rick Anderson](#)

ASP.NET Core configures app behavior based on the runtime environment using an environment variable.

[View or download sample code \(how to download\)](#)

## Environments

ASP.NET Core reads the environment variable `ASPNETCORE_ENVIRONMENT` at app startup and stores the value in `IHostingEnvironment.EnvironmentName`. You can set `ASPNETCORE_ENVIRONMENT` to any value, but [three values](#) are supported by the framework: [Development](#), [Staging](#), and [Production](#). If `ASPNETCORE_ENVIRONMENT` isn't set, it defaults to `Production`.

```
public void Configure(IApplicationBuilder app, IHostingEnvironment env)
{
    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
    }

    if (env.IsProduction() || env.IsStaging() || env.IsEnvironment("Staging_2"))
    {
        app.UseExceptionHandler("/Error");
        app.UseHsts();
    }

    app.UseHttpsRedirection();
    app.UseStaticFiles();
    app.UseCookiePolicy();
    app.UseMvc();
}
```

The preceding code:

- Calls [UseDeveloperExceptionPage](#) and [UseBrowserLink](#) when `ASPNETCORE_ENVIRONMENT` is set to `Development`.
- Calls [UseExceptionHandler](#) when the value of `ASPNETCORE_ENVIRONMENT` is set one of the following:
  - `Staging`
  - `Production`
  - `Staging_2`

The [Environment Tag Helper](#) uses the value of `IHostingEnvironment.EnvironmentName` to include or exclude markup in the element:

```

@page
@inject Microsoft.AspNetCore.Hosting.IHostingEnvironment hostingEnv
@model AboutModel
 @{
     ViewData["Title"] = "About";
 }
<h2>@ViewData["Title"]</h2>
<h3>@Model.Message</h3>

<p> ASPNETCORE_ENVIRONMENT = @hostingEnv.EnvironmentName</p>

```

On Windows and macOS, environment variables and values aren't case sensitive. Linux environment variables and values are **case sensitive** by default.

## Development

The development environment can enable features that shouldn't be exposed in production. For example, the ASP.NET Core templates enable the [developer exception page](#) in the development environment.

The environment for local machine development can be set in the *Properties\launchSettings.json* file of the project. Environment values set in *launchSettings.json* override values set in the system environment.

The following JSON shows three profiles from a *launchSettings.json* file:

```
{
  "iisSettings": {
    "windowsAuthentication": false,
    "anonymousAuthentication": true,
    "iisExpress": {
      "applicationUrl": "http://localhost:54339/",
      "sslPort": 0
    }
  },
  "profiles": {
    "IIS Express": {
      "commandName": "IISExpress",
      "launchBrowser": true,
      "environmentVariables": {
        "ASPNETCORE_My_Environment": "1",
        "ASPNETCORE_DETAILEDERRORS": "1",
        "ASPNETCORE_ENVIRONMENT": "Staging"
      }
    },
    "EnvironmentsSample": {
      "commandName": "Project",
      "launchBrowser": true,
      "environmentVariables": {
        "ASPNETCORE_ENVIRONMENT": "Staging"
      },
      "applicationUrl": "http://localhost:54340/"
    },
    "Kestrel Staging": {
      "commandName": "Project",
      "launchBrowser": true,
      "environmentVariables": {
        "ASPNETCORE_My_Environment": "1",
        "ASPNETCORE_DETAILEDERRORS": "1",
        "ASPNETCORE_ENVIRONMENT": "Staging"
      },
      "applicationUrl": "http://localhost:51997/"
    }
  }
}
```

## NOTE

The `applicationUrl` property in `launchSettings.json` can specify a list of server URLs. Use a semicolon between the URLs in the list:

```
"EnvironmentsSample": {  
    "commandName": "Project",  
    "launchBrowser": true,  
    "applicationUrl": "https://localhost:5001;http://localhost:5000",  
    "environmentVariables": {  
        "ASPNETCORE_ENVIRONMENT": "Development"  
    }  
}
```

When the app is launched with `dotnet run`, the first profile with `"commandName": "Project"` is used. The value of `commandName` specifies the web server to launch. `commandName` can be any one of the following:

- IIS Express
- IIS
- Project (which launches Kestrel)

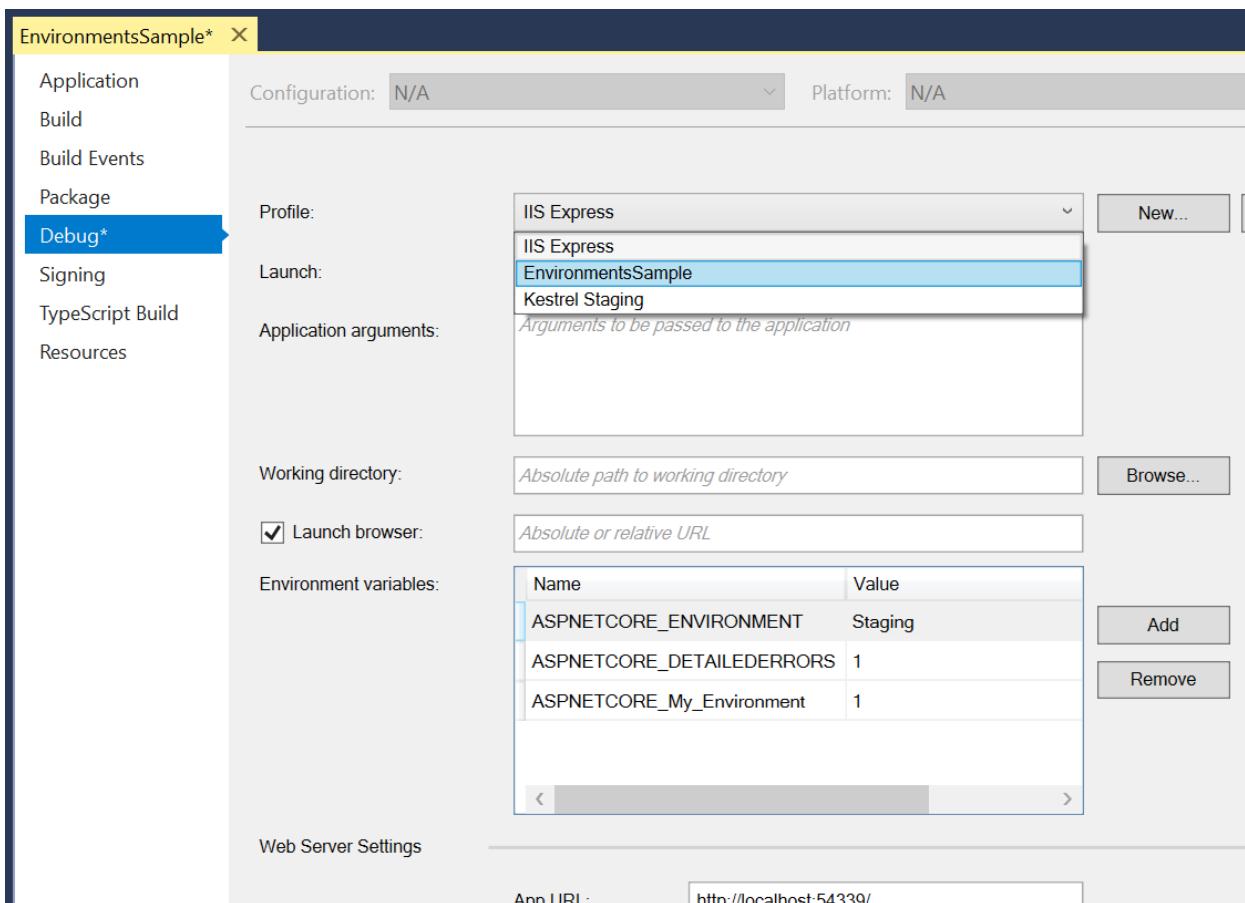

When an app is launched with `dotnet run`:

- `launchSettings.json` is read if available. `environmentVariables` settings in `launchSettings.json` override environment variables.
- The hosting environment is displayed.

The following output shows an app started with `dotnet run`:

```
PS C:\Websites\EnvironmentsSample> dotnet run  
Using launch settings from C:\Websites\EnvironmentsSample\Properties\launchSettings.json...  
Hosting environment: Staging  
Content root path: C:\Websites\EnvironmentsSample  
Now listening on: http://localhost:54340  
Application started. Press Ctrl+C to shut down.
```

The Visual Studio project properties **Debug** tab provides a GUI to edit the `launchSettings.json` file:

### WARNING

*launchSettings.json* shouldn't store secrets. The [Secret Manager tool](#) can be used to store secrets for local development.

When using [Visual Studio Code](#), environment variables can be set in the `.vscode/launch.json` file. The following example sets the environment to `Development`:

```
{  
  "version": "0.2.0",  
  "configurations": [  
    {  
      "name": ".NET Core Launch (web)",  
      ... additional VS Code configuration settings ...  
      "env": {  
        "ASPNETCORE_ENVIRONMENT": "Development"  
      }  
    ]  
}
```

A `.vscode/launch.json` file in the project isn't read when starting the app with `dotnet run` in the same way as `Properties/launchSettings.json`. When launching an app in development that doesn't have a `launchSettings.json` file, either set the environment with an environment variable or a command-line argument to the `dotnet run` command.

### Production

The production environment should be configured to maximize security, performance, and app robustness. Some common settings that differ from development include:

- Caching.
- Client-side resources are bundled, minified, and potentially served from a CDN.
- Diagnostic error pages disabled.
- Friendly error pages enabled.
- Production logging and monitoring enabled. For example, [Application Insights](#).

## Set the environment

It's often useful to set a specific environment for testing. If the environment isn't set, it defaults to `Production`, which disables most debugging features. The method for setting the environment depends on the operating system.

### Azure App Service

To set the environment in [Azure App Service](#), perform the following steps:

1. Select the app from the **App Services** blade.
2. In the **SETTINGS** group, select the **Application settings** blade.
3. In the **Application settings** area, select **Add new setting**.
4. For **Enter a name**, provide `ASPNETCORE_ENVIRONMENT`. For **Enter a value**, provide the environment (for example, `staging`).
5. Select the **Slot Setting** check box if you wish the environment setting to remain with the current slot when deployment slots are swapped. For more information, see [Azure Documentation: Which settings are swapped?](#).
6. Select **Save** at the top of the blade.

Azure App Service automatically restarts the app after an app setting (environment variable) is added, changed, or deleted in the Azure portal.

### Windows

To set the `ASPNETCORE_ENVIRONMENT` for the current session when the app is started using `dotnet run`, the following commands are used:

#### Command prompt

```
set ASPNETCORE_ENVIRONMENT=Development
```

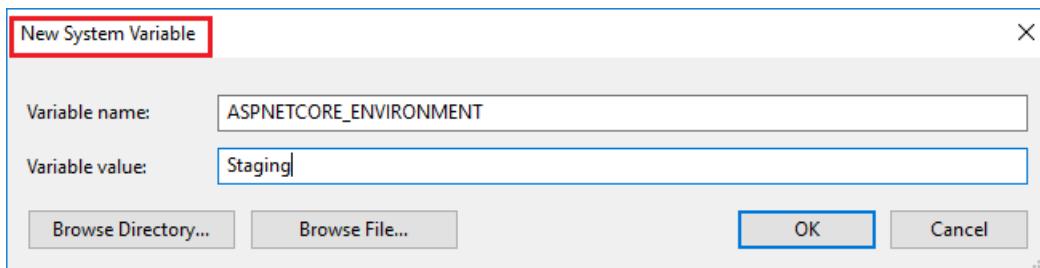

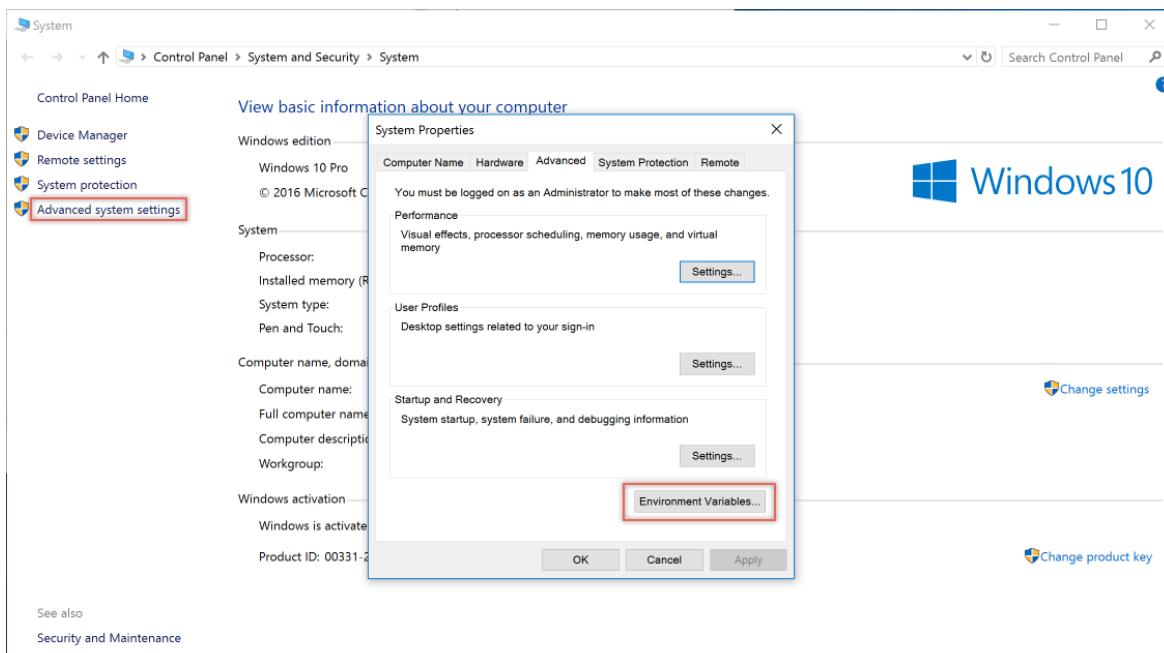

#### PowerShell

```
$Env:ASPNETCORE_ENVIRONMENT = "Development"
```

These commands only take effect for the current window. When the window is closed, the `ASPNETCORE_ENVIRONMENT` setting reverts to the default setting or machine value.

To set the value globally in Windows, use either of the following approaches:

- Open the **Control Panel > System > Advanced system settings** and add or edit the `ASPNETCORE_ENVIRONMENT` value:

- Open an administrative command prompt and use the `setx` command or open an administrative PowerShell command prompt and use `[Environment]::SetEnvironmentVariable`:

### Command prompt

```
setx ASPNETCORE_ENVIRONMENT=Development /M
```

The `/M` switch indicates to set the environment variable at the system level. If the `/M` switch isn't used, the environment variable is set for the user account.

### PowerShell

```
[Environment]::SetEnvironmentVariable("ASPNETCORE_ENVIRONMENT", "Development", "Machine")
```

The `Machine` option value indicates to set the environment variable at the system level. If the option value is changed to `user`, the environment variable is set for the user account.

When the `ASPNETCORE_ENVIRONMENT` environment variable is set globally, it takes effect for `dotnet run` in any command window opened after the value is set.

### web.config

To set the `ASPNETCORE_ENVIRONMENT` environment variable with `web.config`, see the *Setting environment variables* section of [ASP.NET Core Module configuration reference](#). When the `ASPNETCORE_ENVIRONMENT` environment variable is set with `web.config`, its value overrides a setting at the system level.

### Per IIS Application Pool

To set the `ASPNETCORE_ENVIRONMENT` environment variable for an app running in an isolated Application Pool

(supported on IIS 10.0 or later), see the [AppCmd.exe command](#) section of the [Environment Variables <environmentVariables>](#) topic. When the `ASPNETCORE_ENVIRONMENT` environment variable is set for an app pool, its value overrides a setting at the system level.

### IMPORTANT

When hosting an app in IIS and adding or changing the `ASPNETCORE_ENVIRONMENT` environment variable, use any one of the following approaches to have the new value picked up by apps:

- Restart an app's app pool.
- Execute `net stop was /y` followed by `net start w3svc` from a command prompt.
- Restart the server.

## macOS

Setting the current environment for macOS can be performed in-line when running the app:

```
ASPNETCORE_ENVIRONMENT=Development dotnet run
```

Alternatively, set the environment with `export` prior to running the app:

```
export ASPNETCORE_ENVIRONMENT=Development
```

Machine-level environment variables are set in the `.bashrc` or `.bash_profile` file. Edit the file using any text editor. Add the following statement:

```
export ASPNETCORE_ENVIRONMENT=Development
```

## Linux

For Linux distros, use the `export` command at a command prompt for session-based variable settings and `bash_profile` file for machine-level environment settings.

### Configuration by environment

See the *Configuration by environment* section of [Configuration in ASP.NET Core](#).

## Environment-based Startup class and methods

### Startup class conventions

When an ASP.NET Core app starts, the [Startup class](#) bootstraps the app. The app can define separate `Startup` classes for different environments (for example, `StartupDevelopment`), and the appropriate `Startup` class is selected at runtime. The class whose name suffix matches the current environment is prioritized. If a matching `Startup{EnvironmentName}` class isn't found, the `Startup` class is used.

To implement environment-based `Startup` classes, create a `Startup{EnvironmentName}` class for each environment in use and a fallback `Startup` class:

```

// Startup class to use in the Development environment
public class StartupDevelopment
{
    public void ConfigureServices(IServiceCollection services)
    {
        ...
    }

    public void Configure(IApplicationBuilder app, IHostingEnvironment env)
    {
        ...
    }
}

// Startup class to use in the Production environment
public class StartupProduction
{
    public void ConfigureServices(IServiceCollection services)
    {
        ...
    }

    public void Configure(IApplicationBuilder app, IHostingEnvironment env)
    {
        ...
    }
}

// Fallback Startup class
// Selected if the environment doesn't match a Startup{EnvironmentName} class
public class Startup
{
    public void ConfigureServices(IServiceCollection services)
    {
        ...
    }

    public void Configure(IApplicationBuilder app, IHostingEnvironment env)
    {
        ...
    }
}

```

Use the [UseStartup\(IWebHostBuilder, String\)](#) overload that accepts an assembly name:

```

public static void Main(string[] args)
{
    CreateWebHostBuilder(args).Build().Run();
}

public static IWebHostBuilder CreateWebHostBuilder(string[] args)
{
    var assemblyName = typeof(Startup).GetTypeInfo().Assembly.FullName;

    return WebHost.CreateDefaultBuilder(args)
        .UseStartup(assemblyName);
}

```

```
public static void Main(string[] args)
{
CreateWebHost(args).Run();
}

public static IWebHost CreateWebHost(string[] args)
{
var assemblyName = typeof(Startup).GetTypeInfo().Assembly.FullName;

return WebHost.CreateDefaultBuilder(args)
.UseStartup(assemblyName)
.Build();
}
```

```
public class Program
{
public static void Main(string[] args)
{
var assemblyName = typeof(Startup).GetTypeInfo().Assembly.FullName;

var host = new WebHostBuilder()
.UseStartup(assemblyName)
.Build();

host.Run();
}
}
```

## Startup method conventions

[Configure](#) and [ConfigureServices](#) support environment-specific versions of the form

`Configure<EnvironmentName>` and `Configure<EnvironmentName>Services` :

```
public class Startup
{
    public Startup(IConfiguration configuration)
    {
        Configuration = configuration;
    }

    public IConfiguration Configuration { get; }

    public void ConfigureServices(IServiceCollection services)
    {
        StartupConfigureServices(services);
    }

    public void ConfigureStagingServices(IServiceCollection services)
    {
        StartupConfigureServices(services);
    }

    private void StartupConfigureServices(IServiceCollection services)
    {
        services.Configure<CookiePolicyOptions>(options =>
        {
            options.CheckConsentNeeded = context => true;
            options.MinimumSameSitePolicy = SameSiteMode.None;
        });

        services.AddMvc()
            .SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
    }

    public void Configure(IApplicationBuilder app, IHostingEnvironment env)
    {
        if (env.IsDevelopment())
        {
            app.UseDeveloperExceptionPage();
        }

        if (env.IsProduction() || env.IsStaging() || env.IsEnvironment("Staging_2"))
        {
            app.UseExceptionHandler("/Error");
            app.UseHsts();
        }

        app.UseHttpsRedirection();
        app.UseStaticFiles();
        app.UseCookiePolicy();
        app.UseMvc();
    }

    public void ConfigureStaging(IApplicationBuilder app, IHostingEnvironment env)
    {
        if (!env.IsStaging())
        {
            throw new Exception("Not staging.");
        }

        app.UseExceptionHandler("/Error");
        app.UseHsts();
        app.UseHttpsRedirection();
        app.UseStaticFiles();
        app.UseCookiePolicy();
        app.UseMvc();
    }
}
```

# Configuration in ASP.NET Core

6/21/2018 • 15 minutes to read • [Edit Online](#)

By [Rick Anderson](#), [Mark Michaelis](#), [Steve Smith](#), [Daniel Roth](#), and [Luke Latham](#)

The Configuration API provides a way to configure an ASP.NET Core web app based on a list of name-value pairs. Configuration is read at runtime from multiple sources. Name-value pairs can be grouped into a multi-level hierarchy.

There are configuration providers for:

- File formats (INI, JSON, and XML).
- Command-line arguments.
- Environment variables.
- In-memory .NET objects.
- The unencrypted [Secret Manager](#) storage.
- An encrypted user store, such as [Azure Key Vault](#).
- Custom providers (installed or created).

Each configuration value maps to a string key. There's built-in binding support to deserialize settings into a custom [POCO](#) object (a simple .NET class with properties).

The options pattern uses options classes to represent groups of related settings. For more information on using the options pattern, see the [Options](#) topic.

[View or download sample code](#) ([how to download](#))

## JSON configuration

The following console app uses the JSON configuration provider:

```

using System;
using System.IO;
// Requires NuGet package
// Microsoft.Extensions.Configuration.Json
using Microsoft.Extensions.Configuration;

public class Program
{
    public static IConfiguration Configuration { get; set; }

    public static void Main(string[] args = null)
    {
        var builder = new ConfigurationBuilder()
            .SetBasePath(Directory.GetCurrentDirectory())
            .AddJsonFile("appsettings.json");

        Configuration = builder.Build();

        Console.WriteLine($"option1 = {Configuration["Option1"]}");
        Console.WriteLine($"option2 = {Configuration["option2"]}");
        Console.WriteLine(
            $"suboption1 = {Configuration["subsection:suboption1"]}");
        Console.WriteLine();

        Console.WriteLine("Wizards:");
        Console.Write($"{Configuration["wizards:0:Name"]}, ");
        Console.WriteLine($"{Configuration["wizards:0:Age"]}");
        Console.Write($"{Configuration["wizards:1:Name"]}, ");
        Console.WriteLine($"{Configuration["wizards:1:Age"]}");
        Console.WriteLine();

        Console.WriteLine("Press a key...");
        Console.ReadKey();
    }
}

```

The app reads and displays the following configuration settings:

```
{
    "option1": "value1_from_json",
    "option2": 2,

    "subsection": {
        "suboption1": "subvalue1_from_json"
    },
    "wizards": [
        {
            "Name": "Gandalf",
            "Age": "1000"
        },
        {
            "Name": "Harry",
            "Age": "17"
        }
    ]
}
```

Configuration consists of a hierarchical list of name-value pairs in which the nodes are separated by a colon ( `:` ). To retrieve a value, access the `Configuration` indexer with the corresponding item's key:

```
Console.WriteLine(
    $"suboption1 = {Configuration["subsection:suboption1"]});
```

To work with arrays in JSON-formatted configuration sources, use an array index as part of the colon-separated string. The following example gets the name of the first item in the preceding `wizards` array:

```
Console.WriteLine(Configuration["wizards:0:Name"]);
// Output: Gandalf
```

Name-value pairs written to the built-in [Configuration](#) providers are **not** persisted. However, a custom provider that saves values can be created. See [custom configuration provider](#).

The preceding sample uses the configuration indexer to read values. To access configuration outside of `Startup`, use the *options pattern*. For more information, see the [Options](#) topic.

## XML configuration

To work with arrays in XML-formatted configuration sources, provide a `name` index to each element. Use the index to access the values:

```
<wizards>
  <wizard name="Gandalf">
    <age>1000</age>
  </wizard>
  <wizard name="Harry">
    <age>17</age>
  </wizard>
</wizards>
```

```
Console.WriteLine(Configuration["wizard:Harry:age"]);
// Output: 17
```

## Configuration by environment

It's typical to have different configuration settings for different environments, for example, development, testing, and production. The `CreateDefaultBuilder` extension method in an ASP.NET Core 2.x app (or using `AddJsonFile` and `AddEnvironmentVariables` directly in an ASP.NET Core 1.x app) adds configuration providers for reading JSON files and system configuration sources:

- `appsettings.json`
- `appsettings.<EnvironmentName>.json`
- Environment variables

ASP.NET Core 1.x apps need to call `AddJsonFile` and `AddEnvironmentVariables`.

See [AddJsonFile](#) for an explanation of the parameters. `reloadOnChange` is only supported in ASP.NET Core 1.1 and later.

Configuration sources are read in the order that they're specified. In the preceding code, the environment variables are read last. Any configuration values set through the environment replace those set in the two previous providers.

Consider the following `appsettings.Staging.json` file:

```
{
    "Logging": {
        "IncludeScopes": false,
        "LogLevel": {
            "System": "Information",
            "Microsoft": "Information"
        }
    },
    "MyConfig": "My Config Value for staging."
}
```

In the following code, `Configure` reads the value of `MyConfig`:

```
public void Configure(IApplicationBuilder app, IHostingEnvironment env)
{
    var myConfig = Configuration["MyConfig"];
    // use myConfig
    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
        app.UseBrowserLink();
    }

    if (env.IsProduction() || env.IsStaging())
    {
        app.UseExceptionHandler("/Error");
    }

    app.UseStaticFiles();
    app.UseMvcWithDefaultRoute();
}
```

The environment is typically set to `Development`, `Staging`, or `Production`. For more information, see [Use multiple environments](#).

Configuration considerations:

- [IOptionsSnapshot](#) can reload configuration data when it changes.
- Configuration keys are **not** case-sensitive.
- **Never** store passwords or other sensitive data in configuration provider code or in plain text configuration files. Don't use production secrets in development or test environments. Specify secrets outside of the project so that they can't be accidentally committed to a source code repository. Learn more about [how to use multiple environments](#) and managing [safe storage of app secrets in development](#).
- For hierarchical config values specified in environment variables, a colon (`:`) may not work on all platforms. Double underscore (`__`) is supported by all platforms.
- When interacting with the configuration API, a colon (`:`) works on all platforms.

## In-memory provider and binding to a POCO class

The following sample shows how to use the in-memory provider and bind to a class:

```

using System;
using System.Collections.Generic;
using Microsoft.Extensions.Configuration;

public class Program
{
    public static IConfiguration Configuration { get; set; }

    public static void Main(string[] args = null)
    {
        var dict = new Dictionary<string, string>
        {
            {"Profile:MachineName", "Rick"},
            {"App:MainWindow:Height", "11"},
            {"App:MainWindow:Width", "11"},
            {"App:MainWindow:Top", "11"},
            {"App:MainWindow:Left", "11"}
        };
        var builder = new ConfigurationBuilder();
        builder.AddInMemoryCollection(dict);

        Configuration = builder.Build();

        Console.WriteLine($"Hello {Configuration["Profile:MachineName"]}");

        var window = new MyWindow();
        // Bind requires NuGet package
        // Microsoft.Extensions.Configuration.Binder
        Configuration.GetSection("App:MainWindow").Bind(window);
        Console.WriteLine($"Left {window.Left}");
        Console.WriteLine();

        Console.WriteLine("Press any key...");
        Console.ReadKey();
    }
}

public class MyWindow
{
    public int Height { get; set; }
    public int Width { get; set; }
    public int Top { get; set; }
    public int Left { get; set; }
}

```

Configuration values are returned as strings, but binding enables the construction of objects. Binding allows the retrieval of POCO objects or even entire object graphs.

## GetValue

The following sample demonstrates the `GetValue<T>` extension method:

```

using System;
using System.Collections.Generic;
using Microsoft.Extensions.Configuration;

public class Program
{
    public static IConfiguration Configuration { get; set; }

    public static void Main(string[] args = null)
    {
        var dict = new Dictionary<string, string>
        {
            {"Profile:MachineName", "Rick"},
            {"App:MainWindow:Height", "11"},
            {"App:MainWindow:Width", "11"},
            {"App:MainWindow:Top", "11"},
            {"App:MainWindow:Left", "11"}
        };
    }

    var builder = new ConfigurationBuilder();
    builder.AddInMemoryCollection(dict);

    Configuration = builder.Build();

    Console.WriteLine($"Hello {Configuration["Profile:MachineName"]}");

    // Show GetValue overload and set the default value to 80
    // Requires NuGet package "Microsoft.Extensions.Configuration.Binder"
    var left = Configuration.GetValue<int>("App:MainWindow:Left", 80);
    Console.WriteLine($"Left {left}");

    var window = new MyWindow();
    Configuration.GetSection("App:MainWindow").Bind(window);
    Console.WriteLine($"Left {window.Left}");
    Console.WriteLine();

    Console.WriteLine("Press a key...");
    Console.ReadKey();
}
}

public class MyWindow
{
    public int Height { get; set; }
    public int Width { get; set; }
    public int Top { get; set; }
    public int Left { get; set; }
}

```

The ConfigurationBinder's `GetValue<T>` method allows the specification of a default value (80 in the sample). `GetValue<T>` is for simple scenarios and doesn't bind to entire sections. `GetValue<T>` obtains scalar values from `GetSection(key).Value` converted to a specific type.

## Bind to an object graph

Each object in a class can be recursively bound. Consider the following `AppSettings` class:

```

public class AppSettings
{
    public Window Window { get; set; }
    public Connection Connection { get; set; }
    public Profile Profile { get; set; }
}

public class Window
{
    public int Height { get; set; }
    public int Width { get; set; }
}

public class Connection
{
    public string Value { get; set; }
}

public class Profile
{
    public string Machine { get; set; }
}

```

The following sample binds to the `AppSettings` class:

```

using System;
using System.IO;
using Microsoft.Extensions.Configuration;

public class Program
{
    public static void Main(string[] args = null)
    {
        var builder = new ConfigurationBuilder()
            .SetBasePath(Directory.GetCurrentDirectory())
            .AddJsonFile("appsettings.json");

        var config = builder.Build();

        var appConfig = new AppSettings();
        config.GetSection("App").Bind(appConfig);

        Console.WriteLine($"Height {appConfig.Window.Height}");
        Console.WriteLine();

        Console.WriteLine("Press a key...");
        Console.ReadKey();
    }
}

```

**ASP.NET Core 1.1** and higher can use `Get<T>`, which works with entire sections. `Get<T>` can be more convenient than using `Bind`. The following code shows how to use `Get<T>` with the preceding sample:

```
var appConfig = config.GetSection("App").Get<AppSettings>();
```

Using the following `appsettings.json` file:

```
{
    "App": {
        "Profile": {
            "Machine": "Rick"
        },
        "Connection": {
            "Value": "connectionstring"
        },
        "Window": {
            "Height": "11",
            "Width": "11"
        }
    }
}
```

The program displays `Height 11`.

The following code can be used to unit test the configuration:

```
[Fact]
public void CanBindObjectTree()
{
    var dict = new Dictionary<string, string>
    {
        {"App:Profile:Machine", "Rick"},
        {"App:Connection:Value", "connectionstring"},
        {"App:Window:Height", "11"},
        {"App:Window:Width", "11"}
    };
    var builder = new ConfigurationBuilder();
    builder.AddInMemoryCollection(dict);
    var config = builder.Build();

    var settings = new AppSettings();
    config.GetSection("App").Bind(settings);

    Assert.Equal("Rick", settings.Profile.Machine);
    Assert.Equal(11, settings.Window.Height);
    Assert.Equal(11, settings.Window.Width);
    Assert.Equal("connectionstring", settings.Connection.Value);
}
```

## Create an Entity Framework custom provider

In this section, a basic configuration provider that reads name-value pairs from a database using EF is created.

Define a `ConfigurationValue` entity for storing configuration values in the database:

```
public class ConfigurationValue
{
    public string Id { get; set; }
    public string Value { get; set; }
}
```

Add a `ConfigurationContext` to store and access the configured values:

```
public class ConfigurationContext : DbContext
{
    public ConfigurationContext(DbContextOptions options) : base(options)
    {
    }

    public DbSet<ConfigurationValue> Values { get; set; }
}
```

Create a class that implements [IConfigurationSource](#):

```
using System;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.Configuration;

namespace CustomConfigurationProvider
{
    public class EFConfigSource : IConfigurationSource
    {
        private readonly Action<DbContextOptionsBuilder> _optionsAction;

        public EFConfigSource(Action<DbContextOptionsBuilder> optionsAction)
        {
            _optionsAction = optionsAction;
        }

        public IConfigurationProvider Build(IConfigurationBuilder builder)
        {
            return new EFConfigProvider(_optionsAction);
        }
    }
}
```

Create the custom configuration provider by inheriting from [ConfigurationProvider](#). The configuration provider initializes the database when it's empty:

```

using System;
using System.Collections.Generic;
using System.Linq;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.Configuration;

namespace CustomConfigurationProvider
{
    public class EFConfigProvider : ConfigurationProvider
    {
        public EFConfigProvider(Action<DbContextOptionsBuilder> optionsAction)
        {
            OptionsAction = optionsAction;
        }

        Action<DbContextOptionsBuilder> OptionsAction { get; }

        // Load config data from EF DB.
        public override void Load()
        {
            var builder = new DbContextOptionsBuilder<ConfigurationContext>();
            OptionsAction(builder);

            using (var dbContext = new ConfigurationContext(builder.Options))
            {
                dbContext.Database.EnsureCreated();
                Data = !dbContext.Values.Any()
                    ? CreateAndSaveDefaultValues(dbContext)
                    : dbContext.Values.ToDictionary(c => c.Id, c => c.Value);
            }
        }

        private static IDictionary<string, string> CreateAndSaveDefaultValues(
            ConfigurationContext dbContext)
        {
            var configValues = new Dictionary<string, string>
            {
                { "key1", "value_from_ef_1" },
                { "key2", "value_from_ef_2" }
            };
            dbContext.Values.AddRange(configValues
                .Select(kvp => new ConfigurationValue { Id = kvp.Key, Value = kvp.Value })
                .ToArray());
            dbContext.SaveChanges();
            return configValues;
        }
    }
}

```

The highlighted values from the database ("value\_from\_ef\_1" and "value\_from\_ef\_2") are displayed when the sample is run.

An `EFConfigSource` extension method for adding the configuration source can be used:

```

using System;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.Configuration;

namespace CustomConfigurationProvider
{
    public static class EntityFrameworkExtensions
    {
        public static IConfigurationBuilder AddEntityFrameworkConfig(
            this IConfigurationBuilder builder, Action<DbContextOptionsBuilder> setup)
        {
            return builder.Add(new EFConfigSource(setup));
        }
    }
}

```

The following code shows how to use the custom `EFConfigProvider`:

```

using System;
using System.IO;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.Configuration;
using CustomConfigurationProvider;

public static class Program
{
    public static void Main()
    {
        var builder = new ConfigurationBuilder()
            .SetBasePath(Directory.GetCurrentDirectory())
            .AddJsonFile("appsettings.json");

        var connectionStringConfig = builder.Build();

        var config = new ConfigurationBuilder()
            .SetBasePath(Directory.GetCurrentDirectory())
            // Add "appsettings.json" to bootstrap EF config.
            .AddJsonFile("appsettings.json")
            // Add the EF configuration provider, which will override any
            // config made with the JSON provider.
            .AddEntityFrameworkConfig(options =>
                options.UseSqlServer(connectionStringConfig.GetConnectionString(
                    "DefaultConnection"))
            )
            .Build();

        Console.WriteLine("key1={0}", config["key1"]);
        Console.WriteLine("key2={0}", config["key2"]);
        Console.WriteLine("key3={0}", config["key3"]);
        Console.WriteLine();

        Console.WriteLine("Press a key...");
        Console.ReadKey();
    }
}

```

Note the sample adds the custom `EFConfigProvider` after the JSON provider, so any settings from the database will override settings from the `appsettings.json` file.

Using the following `appsettings.json` file:

```
{  
    "ConnectionStrings": {  
        "DefaultConnection": "Server=  
        (localdb)\\mssqllocaldb;Database=CustomConfigurationProvider;Trusted_Connection=True;MultipleActiveResultSets=t  
        rue"  
    },  
    "key1": "value_from_json_1",  
    "key2": "value_from_json_2",  
    "key3": "value_from_json_3"  
}
```

The following output is displayed:

```
key1=value_from_ef_1  
key2=value_from_ef_2  
key3=value_from_json_3
```

## CommandLine configuration provider

The [CommandLine configuration provider](#) receives command-line argument key-value pairs for configuration at runtime.

[View or download the CommandLine configuration sample](#)

### Setup and use the CommandLine configuration provider

- [Basic Configuration](#)
- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

To activate command-line configuration, call the `AddCommandLine` extension method on an instance of `ConfigurationBuilder`:

```

using System;
using System.Collections.Generic;
using System.Linq;
using Microsoft.Extensions.Configuration;

public class Program
{
    public static IConfiguration Configuration { get; set; }

    public static void Main(string[] args = null)
    {
        var dict = new Dictionary<string, string>
        {
            {"Profile:MachineName", "MairaPC"},
            {"App:MainWindow:Left", "1980"}
        };

        var builder = new ConfigurationBuilder();

        builder.AddInMemoryCollection(dict)
            .AddCommandLine(args);

        Configuration = builder.Build();

        Console.WriteLine($"MachineName: {Configuration["Profile:MachineName"]}");
        Console.WriteLine($"Left: {Configuration["App:MainWindow:Left"]}");
        Console.WriteLine();

        Console.WriteLine("Press a key...");
        Console.ReadKey();
    }
}

```

Running the code, the following output is displayed:

```

MachineName: MairaPC
Left: 1980

```

Passing argument key-value pairs on the command line changes the values of `Profile:MachineName` and `App:MainWindow:Left`:

```
dotnet run Profile:MachineName=BartPC App:MainWindow:Left=1979
```

The console window displays:

```

MachineName: BartPC
Left: 1979

```

To override configuration provided by other configuration providers with command-line configuration, call `AddCommandLine` last on `ConfigurationBuilder`:

```

var config = new ConfigurationBuilder()
    .SetBasePath(Directory.GetCurrentDirectory())
    .AddJsonFile("appsettings.json", optional: true, reloadOnChange: true)
    .AddEnvironmentVariables()
    .AddCommandLine(args)
    .Build();

```

## Arguments

Arguments passed on the command line must conform to one of two formats shown in the following table:

ARGUMENT FORMAT	EXAMPLE
Single argument: a key-value pair separated by an equals sign ( <code>=</code> )	<code>key1=value</code>
Sequence of two arguments: a key-value pair separated by a space	<code>/key1 value1</code>

### Single argument

The value must follow an equals sign (`=`). The value can be null (for example, `mykey=`).

The key may have a prefix.

KEY PREFIX	EXAMPLE
No prefix	<code>key1=value1</code>
Single dash ( <code>-</code> ) <sup>†</sup>	<code>-key2=value2</code>
Two dashes ( <code>--</code> )	<code>--key3=value3</code>
Forward slash ( <code>/</code> )	<code>/key4=value4</code>

<sup>†</sup>A key with a single dash prefix (`-`) must be provided in [switch mappings](#), described below.

Example command:

```
dotnet run key1=value1 -key2=value2 --key3=value3 /key4=value4
```

Note: If `-key2` isn't present in the [switch mappings](#) given to the configuration provider, a `FormatException` is thrown.

### Sequence of two arguments

The value can't be null and must follow the key separated by a space.

The key must have a prefix.

KEY PREFIX	EXAMPLE
Single dash ( <code>-</code> ) <sup>†</sup>	<code>-key1 value1</code>
Two dashes ( <code>--</code> )	<code>--key2 value2</code>
Forward slash ( <code>/</code> )	<code>/key3 value3</code>

<sup>†</sup>A key with a single dash prefix (`-`) must be provided in [switch mappings](#), described below.

Example command:

```
dotnet run -key1 value1 --key2 value2 /key3 value3
```

Note: If `-key1` isn't present in the [switch mappings](#) given to the configuration provider, a `FormatException` is thrown.

## Duplicate keys

If duplicate keys are provided, the last key-value pair is used.

## Switch mappings

When manually building configuration with `ConfigurationBuilder`, a switch mappings dictionary can be added to the `AddCommandLine` method. Switch mappings allow key name replacement logic.

When the switch mappings dictionary is used, the dictionary is checked for a key that matches the key provided by a command-line argument. If the command-line key is found in the dictionary, the dictionary value (the key replacement) is passed back to set the configuration. A switch mapping is required for any command-line key prefixed with a single dash (`-`).

Switch mappings dictionary key rules:

- Switches must start with a dash (`-`) or double-dash (`--`).
- The switch mappings dictionary must not contain duplicate keys.

In the following example, the `GetSwitchMappings` method allows command-line arguments to use a single dash (`-`) key prefix and avoid leading subkey prefixes.

```

using System;
using System.Collections.Generic;
using System.Linq;
using Microsoft.Extensions.Configuration;

public class Program
{
    public static IConfiguration Configuration { get; set; }

    public static Dictionary<string, string> GetSwitchMappings(
        IReadOnlyDictionary<string, string> configurationStrings)
    {
        return configurationStrings.Select(item =>
            new KeyValuePair<string, string>(
                "-" + item.Key.Substring(item.Key.LastIndexOf(':') + 1),
                item.Key))
            .ToDictionary(
                item => item.Key, item => item.Value);
    }

    public static void Main(string[] args = null)
    {
        var dict = new Dictionary<string, string>
        {
            {"Profile:MachineName", "RickPC"},
            {"App:MainWindow:Left", "1980"}
        };

        var builder = new ConfigurationBuilder();

        builder.AddInMemoryCollection(dict)
            .AddCommandLine(args, GetSwitchMappings(dict));

        Configuration = builder.Build();

        Console.WriteLine($"MachineName: {Configuration["Profile:MachineName"]}");
        Console.WriteLine($"Left: {Configuration["App:MainWindow:Left"]}");
        Console.WriteLine();

        Console.WriteLine("Press a key...");
        Console.ReadKey();
    }
}

```

Without providing command-line arguments, the dictionary provided to `AddInMemoryCollection` sets the configuration values. Run the app with the following command:

```
dotnet run
```

The console window displays:

```
MachineName: RickPC
Left: 1980
```

Use the following to pass in configuration settings:

```
dotnet run /Profile:MachineName=DahliaPC /App:MainWindow:Left=1984
```

The console window displays:

```
MachineName: DahliaPC
Left: 1984
```

After the switch mappings dictionary is created, it contains the data shown in the following table:

KEY	VALUE
-MachineName	Profile:MachineName
-Left	App:MainWindow:Left

To demonstrate key switching using the dictionary, run the following command:

```
dotnet run -MachineName=ChadPC -Left=1988
```

The command-line keys are swapped. The console window displays the configuration values for `Profile:MachineName` and `App:MainWindow:Left`:

```
MachineName: ChadPC
Left: 1988
```

## web.config file

A `web.config` file is required when hosting the app in IIS or IIS Express. Settings in `web.config` enable the [ASP.NET Core Module](#) to launch the app and configure other IIS settings and modules. If the `web.config` file isn't present and the project file includes `<Project Sdk="Microsoft.NET.Sdk.Web">`, publishing the project creates a `web.config` file in the published output (the *publish* folder). For more information, see [Host ASP.NET Core on Windows with IIS](#).

## Access configuration during startup

To access configuration within `ConfigureServices` or `Configure` during startup, see the examples in the [Application startup](#) topic.

## Adding configuration from an external assembly

An [IHostingStartup](#) implementation allows adding enhancements to an app at startup from an external assembly outside of the app's `Startup` class. For more information, see [Enhance an app from an external assembly](#).

## Access configuration in a Razor Page or MVC view

To access configuration settings in a Razor Pages page or an MVC view, add a [using directive \(C# reference: using directive\)](#) for the [Microsoft.Extensions.Configuration namespace](#) and inject  [IConfiguration](#) into the page or view.

In a Razor Pages page:

```

@page
@model IndexModel

@using Microsoft.Extensions.Configuration
@inject IConfiguration Configuration

<!DOCTYPE html>
<html lang="en">
<head>
    <title>Index Page</title>
</head>
<body>
    <h1>Access configuration in a Razor Pages page</h1>
    <p>Configuration["key"]:</p>
</body>
</html>

```

In an MVC view:

```

@using Microsoft.Extensions.Configuration
@inject IConfiguration Configuration

<!DOCTYPE html>
<html lang="en">
<head>
    <title>Index View</title>
</head>
<body>
    <h1>Access configuration in an MVC view</h1>
    <p>Configuration["key"]:</p>
</body>
</html>

```

## Additional notes

- Dependency Injection (DI) isn't set up until after `ConfigureServices` is invoked.
- The configuration system isn't DI aware.
- `IConfiguration` has two specializations:
  - `IConfigurationRoot` Used for the root node. Can trigger a reload.
  - `IConfigurationSection` Represents a section of configuration values. The `GetSection` and `GetChildren` methods return an `IConfigurationSection`.
  - Use `IConfigurationRoot` when reloading configuration or for access to each provider. Neither of these situations are common.

# Configuration in ASP.NET Core

6/21/2018 • 15 minutes to read • [Edit Online](#)

By [Rick Anderson](#), [Mark Michaelis](#), [Steve Smith](#), [Daniel Roth](#), and [Luke Latham](#)

The Configuration API provides a way to configure an ASP.NET Core web app based on a list of name-value pairs. Configuration is read at runtime from multiple sources. Name-value pairs can be grouped into a multi-level hierarchy.

There are configuration providers for:

- File formats (INI, JSON, and XML).
- Command-line arguments.
- Environment variables.
- In-memory .NET objects.
- The unencrypted [Secret Manager](#) storage.
- An encrypted user store, such as [Azure Key Vault](#).
- Custom providers (installed or created).

Each configuration value maps to a string key. There's built-in binding support to deserialize settings into a custom [POCO](#) object (a simple .NET class with properties).

The options pattern uses options classes to represent groups of related settings. For more information on using the options pattern, see the [Options](#) topic.

[View or download sample code \(how to download\)](#)

## JSON configuration

The following console app uses the JSON configuration provider:

```

using System;
using System.IO;
// Requires NuGet package
// Microsoft.Extensions.Configuration.Json
using Microsoft.Extensions.Configuration;

public class Program
{
    public static IConfiguration Configuration { get; set; }

    public static void Main(string[] args = null)
    {
        var builder = new ConfigurationBuilder()
            .SetBasePath(Directory.GetCurrentDirectory())
            .AddJsonFile("appsettings.json");

        Configuration = builder.Build();

        Console.WriteLine($"option1 = {Configuration["Option1"]}");
        Console.WriteLine($"option2 = {Configuration["option2"]}");
        Console.WriteLine(
            $"suboption1 = {Configuration["subsection:suboption1"]}");
        Console.WriteLine();

        Console.WriteLine("Wizards:");
        Console.Write($"{Configuration["wizards:0:Name"]}, ");
        Console.WriteLine($"{Configuration["wizards:0:Age"]}");
        Console.Write($"{Configuration["wizards:1:Name"]}, ");
        Console.WriteLine($"{Configuration["wizards:1:Age"]}");
        Console.WriteLine();

        Console.WriteLine("Press a key...");
        Console.ReadKey();
    }
}

```

The app reads and displays the following configuration settings:

```
{
    "option1": "value1_from_json",
    "option2": 2,

    "subsection": {
        "suboption1": "subvalue1_from_json"
    },
    "wizards": [
        {
            "Name": "Gandalf",
            "Age": "1000"
        },
        {
            "Name": "Harry",
            "Age": "17"
        }
    ]
}
```

Configuration consists of a hierarchical list of name-value pairs in which the nodes are separated by a colon ( : ). To retrieve a value, access the `Configuration` indexer with the corresponding item's key:

```

Console.WriteLine(
    $"suboption1 = {Configuration["subsection:suboption1"]}");

```

To work with arrays in JSON-formatted configuration sources, use an array index as part of the colon-separated string. The following example gets the name of the first item in the preceding `wizards` array:

```
Console.WriteLine("${Configuration["wizards:0:Name"]}");
// Output: Gandalf
```

Name-value pairs written to the built-in [Configuration](#) providers are **not** persisted. However, a custom provider that saves values can be created. See [custom configuration provider](#).

The preceding sample uses the configuration indexer to read values. To access configuration outside of `Startup`, use the *options pattern*. For more information, see the [Options](#) topic.

## XML configuration

To work with arrays in XML-formatted configuration sources, provide a `name` index to each element. Use the index to access the values:

```
<wizards>
  <wizard name="Gandalf">
    <age>1000</age>
  </wizard>
  <wizard name="Harry">
    <age>17</age>
  </wizard>
</wizards>
```

```
Console.WriteLine("${Configuration["wizard:Harry:age"]}");
// Output: 17
```

## Configuration by environment

It's typical to have different configuration settings for different environments, for example, development, testing, and production. The `createDefaultBuilder` extension method in an ASP.NET Core 2.x app (or using `AddJsonFile` and `AddEnvironmentVariables` directly in an ASP.NET Core 1.x app) adds configuration providers for reading JSON files and system configuration sources:

- `appsettings.json`
- `appsettings.<EnvironmentName>.json`
- Environment variables

ASP.NET Core 1.x apps need to call `AddJsonFile` and [AddEnvironmentVariables](#).

See [AddJsonFile](#) for an explanation of the parameters. `reloadOnChange` is only supported in ASP.NET Core 1.1 and later.

Configuration sources are read in the order that they're specified. In the preceding code, the environment variables are read last. Any configuration values set through the environment replace those set in the two previous providers.

Consider the following `appsettings.Staging.json` file:

```
{
    "Logging": {
        "IncludeScopes": false,
        "LogLevel": {
            "System": "Information",
            "Microsoft": "Information"
        }
    },
    "MyConfig": "My Config Value for staging."
}
```

In the following code, `Configure` reads the value of `MyConfig`:

```
public void Configure(IApplicationBuilder app, IHostingEnvironment env)
{
    var myConfig = Configuration["MyConfig"];
    // use myConfig
    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
        app.UseBrowserLink();
    }

    if (env.IsProduction() || env.IsStaging())
    {
        app.UseExceptionHandler("/Error");
    }

    app.UseStaticFiles();
    app.UseMvcWithDefaultRoute();
}
```

The environment is typically set to `Development`, `Staging`, or `Production`. For more information, see [Use multiple environments](#).

Configuration considerations:

- [IOptionsSnapshot](#) can reload configuration data when it changes.
- Configuration keys are **not** case-sensitive.
- **Never** store passwords or other sensitive data in configuration provider code or in plain text configuration files. Don't use production secrets in development or test environments. Specify secrets outside of the project so that they can't be accidentally committed to a source code repository. Learn more about [how to use multiple environments](#) and managing [safe storage of app secrets in development](#).
- For hierarchical config values specified in environment variables, a colon (`:`) may not work on all platforms. Double underscore (`__`) is supported by all platforms.
- When interacting with the configuration API, a colon (`:`) works on all platforms.

## In-memory provider and binding to a POCO class

The following sample shows how to use the in-memory provider and bind to a class:

```

using System;
using System.Collections.Generic;
using Microsoft.Extensions.Configuration;

public class Program
{
    public static IConfiguration Configuration { get; set; }

    public static void Main(string[] args = null)
    {
        var dict = new Dictionary<string, string>
        {
            {"Profile:MachineName", "Rick"},
            {"App:MainWindow:Height", "11"},
            {"App:MainWindow:Width", "11"},
            {"App:MainWindow:Top", "11"},
            {"App:MainWindow:Left", "11"}
        };
    }

    var builder = new ConfigurationBuilder();
    builder.AddInMemoryCollection(dict);

    Configuration = builder.Build();

    Console.WriteLine($"Hello {Configuration["Profile:MachineName"]}");

    var window = new MyWindow();
    // Bind requires NuGet package
    // Microsoft.Extensions.Configuration.Binder
    Configuration.GetSection("App:MainWindow").Bind(window);
    Console.WriteLine($"Left {window.Left}");
    Console.WriteLine();

    Console.WriteLine("Press any key...");
    Console.ReadKey();
}
}

public class MyWindow
{
    public int Height { get; set; }
    public int Width { get; set; }
    public int Top { get; set; }
    public int Left { get; set; }
}

```

Configuration values are returned as strings, but binding enables the construction of objects. Binding allows the retrieval of POCO objects or even entire object graphs.

## GetValue

The following sample demonstrates the `GetValue<T>` extension method:

```

using System;
using System.Collections.Generic;
using Microsoft.Extensions.Configuration;

public class Program
{
    public static IConfiguration Configuration { get; set; }

    public static void Main(string[] args = null)
    {
        var dict = new Dictionary<string, string>
        {
            {"Profile:MachineName", "Rick"},
            {"App:MainWindow:Height", "11"},
            {"App:MainWindow:Width", "11"},
            {"App:MainWindow:Top", "11"},
            {"App:MainWindow:Left", "11"}
        };
    }

    var builder = new ConfigurationBuilder();
    builder.AddInMemoryCollection(dict);

    Configuration = builder.Build();

    Console.WriteLine($"Hello {Configuration["Profile:MachineName"]}");

    // Show GetValue overload and set the default value to 80
    // Requires NuGet package "Microsoft.Extensions.Configuration.Binder"
    var left = Configuration.GetValue<int>("App:MainWindow:Left", 80);
    Console.WriteLine($"Left {left}");

    var window = new MyWindow();
    Configuration.GetSection("App:MainWindow").Bind(window);
    Console.WriteLine($"Left {window.Left}");
    Console.WriteLine();

    Console.WriteLine("Press a key...");
    Console.ReadKey();
}
}

public class MyWindow
{
    public int Height { get; set; }
    public int Width { get; set; }
    public int Top { get; set; }
    public int Left { get; set; }
}

```

The ConfigurationBinder's `GetValue<T>` method allows the specification of a default value (80 in the sample). `GetValue<T>` is for simple scenarios and doesn't bind to entire sections. `GetValue<T>` obtains scalar values from `GetSection(key).Value` converted to a specific type.

## Bind to an object graph

Each object in a class can be recursively bound. Consider the following `AppSettings` class:

```

public class AppSettings
{
    public Window Window { get; set; }
    public Connection Connection { get; set; }
    public Profile Profile { get; set; }
}

public class Window
{
    public int Height { get; set; }
    public int Width { get; set; }
}

public class Connection
{
    public string Value { get; set; }
}

public class Profile
{
    public string Machine { get; set; }
}

```

The following sample binds to the `AppSettings` class:

```

using System;
using System.IO;
using Microsoft.Extensions.Configuration;

public class Program
{
    public static void Main(string[] args = null)
    {
        var builder = new ConfigurationBuilder()
            .SetBasePath(Directory.GetCurrentDirectory())
            .AddJsonFile("appsettings.json");

        var config = builder.Build();

        var appConfig = new AppSettings();
        config.GetSection("App").Bind(appConfig);

        Console.WriteLine($"Height {appConfig.Window.Height}");
        Console.WriteLine();

        Console.WriteLine("Press a key...");
        Console.ReadKey();
    }
}

```

**ASP.NET Core 1.1** and higher can use `Get<T>`, which works with entire sections. `Get<T>` can be more convenient than using `Bind`. The following code shows how to use `Get<T>` with the preceding sample:

```
var appConfig = config.GetSection("App").Get<AppSettings>();
```

Using the following `appsettings.json` file:

```
{
    "App": {
        "Profile": {
            "Machine": "Rick"
        },
        "Connection": {
            "Value": "connectionstring"
        },
        "Window": {
            "Height": "11",
            "Width": "11"
        }
    }
}
```

The program displays `Height 11`.

The following code can be used to unit test the configuration:

```
[Fact]
public void CanBindObjectTree()
{
    var dict = new Dictionary<string, string>
    {
        {"App:Profile:Machine", "Rick"},
        {"App:Connection:Value", "connectionstring"},
        {"App:Window:Height", "11"},
        {"App:Window:Width", "11"}
    };
    var builder = new ConfigurationBuilder();
    builder.AddInMemoryCollection(dict);
    var config = builder.Build();

    var settings = new AppSettings();
    config.GetSection("App").Bind(settings);

    Assert.Equal("Rick", settings.Profile.Machine);
    Assert.Equal(11, settings.Window.Height);
    Assert.Equal(11, settings.Window.Width);
    Assert.Equal("connectionstring", settings.Connection.Value);
}
```

## Create an Entity Framework custom provider

In this section, a basic configuration provider that reads name-value pairs from a database using EF is created.

Define a `ConfigurationValue` entity for storing configuration values in the database:

```
public class ConfigurationValue
{
    public string Id { get; set; }
    public string Value { get; set; }
}
```

Add a `ConfigurationContext` to store and access the configured values:

```
public class ConfigurationContext : DbContext
{
    public ConfigurationContext(DbContextOptions options) : base(options)
    {
    }

    public DbSet<ConfigurationValue> Values { get; set; }
}
```

Create a class that implements [IConfigurationSource](#):

```
using System;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.Configuration;

namespace CustomConfigurationProvider
{
    public class EFConfigSource : IConfigurationSource
    {
        private readonly Action<DbContextOptionsBuilder> _optionsAction;

        public EFConfigSource(Action<DbContextOptionsBuilder> optionsAction)
        {
            _optionsAction = optionsAction;
        }

        public IConfigurationProvider Build(IConfigurationBuilder builder)
        {
            return new EFConfigProvider(_optionsAction);
        }
    }
}
```

Create the custom configuration provider by inheriting from [ConfigurationProvider](#). The configuration provider initializes the database when it's empty:

```

using System;
using System.Collections.Generic;
using System.Linq;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.Configuration;

namespace CustomConfigurationProvider
{
    public class EFConfigProvider : ConfigurationProvider
    {
        public EFConfigProvider(Action<DbContextOptionsBuilder> optionsAction)
        {
            OptionsAction = optionsAction;
        }

        Action<DbContextOptionsBuilder> OptionsAction { get; }

        // Load config data from EF DB.
        public override void Load()
        {
            var builder = new DbContextOptionsBuilder<ConfigurationContext>();
            OptionsAction(builder);

            using (var dbContext = new ConfigurationContext(builder.Options))
            {
                dbContext.Database.EnsureCreated();
                Data = !dbContext.Values.Any()
                    ? CreateAndSaveDefaultValues(dbContext)
                    : dbContext.Values.ToDictionary(c => c.Id, c => c.Value);
            }
        }

        private static IDictionary<string, string> CreateAndSaveDefaultValues(
            ConfigurationContext dbContext)
        {
            var configValues = new Dictionary<string, string>
            {
                { "key1", "value_from_ef_1" },
                { "key2", "value_from_ef_2" }
            };
            dbContext.Values.AddRange(configValues
                .Select(kvp => new ConfigurationValue { Id = kvp.Key, Value = kvp.Value })
                .ToArray());
            dbContext.SaveChanges();
            return configValues;
        }
    }
}

```

The highlighted values from the database ("value\_from\_ef\_1" and "value\_from\_ef\_2") are displayed when the sample is run.

An `EFConfigSource` extension method for adding the configuration source can be used:

```

using System;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.Configuration;

namespace CustomConfigurationProvider
{
    public static class EntityFrameworkExtensions
    {
        public static IConfigurationBuilder AddEntityFrameworkConfig(
            this IConfigurationBuilder builder, Action<DbContextOptionsBuilder> setup)
        {
            return builder.Add(new EFConfigSource(setup));
        }
    }
}

```

The following code shows how to use the custom `EFConfigProvider`:

```

using System;
using System.IO;
using Microsoft.EntityFrameworkCore;
using Microsoft.Extensions.Configuration;
using CustomConfigurationProvider;

public static class Program
{
    public static void Main()
    {
        var builder = new ConfigurationBuilder()
            .SetBasePath(Directory.GetCurrentDirectory())
            .AddJsonFile("appsettings.json");

        var connectionStringConfig = builder.Build();

        var config = new ConfigurationBuilder()
            .SetBasePath(Directory.GetCurrentDirectory())
            // Add "appsettings.json" to bootstrap EF config.
            .AddJsonFile("appsettings.json")
            // Add the EF configuration provider, which will override any
            // config made with the JSON provider.
            .AddEntityFrameworkConfig(options =>
                options.UseSqlServer(connectionStringConfig.GetConnectionString(
                    "DefaultConnection"))
            )
            .Build();

        Console.WriteLine("key1={0}", config["key1"]);
        Console.WriteLine("key2={0}", config["key2"]);
        Console.WriteLine("key3={0}", config["key3"]);
        Console.WriteLine();

        Console.WriteLine("Press a key...");
        Console.ReadKey();
    }
}

```

Note the sample adds the custom `EFConfigProvider` after the JSON provider, so any settings from the database will override settings from the `appsettings.json` file.

Using the following `appsettings.json` file:

```
{  
    "ConnectionStrings": {  
        "DefaultConnection": "Server=localdb\\mssqllocaldb;Database=CustomConfigurationProvider;Trusted_Connection=True;MultipleActiveResultSets=true"  
    },  
    "key1": "value_from_ef_1",  
    "key2": "value_from_ef_2",  
    "key3": "value_from_json_3"  
}
```

The following output is displayed:

```
key1=value_from_ef_1  
key2=value_from_ef_2  
key3=value_from_json_3
```

## CommandLine configuration provider

The [CommandLine configuration provider](#) receives command-line argument key-value pairs for configuration at runtime.

[View or download the CommandLine configuration sample](#)

### Setup and use the CommandLine configuration provider

- [Basic Configuration](#)
- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

To activate command-line configuration, call the `AddCommandLine` extension method on an instance of `ConfigurationBuilder`:

```

using System;
using System.Collections.Generic;
using System.Linq;
using Microsoft.Extensions.Configuration;

public class Program
{
    public static IConfiguration Configuration { get; set; }

    public static void Main(string[] args = null)
    {
        var dict = new Dictionary<string, string>
        {
            {"Profile:MachineName", "MairaPC"},
            {"App:MainWindow:Left", "1980"}
        };

        var builder = new ConfigurationBuilder();

        builder.AddInMemoryCollection(dict)
            .AddCommandLine(args);

        Configuration = builder.Build();

        Console.WriteLine($"MachineName: {Configuration["Profile:MachineName"]}");
        Console.WriteLine($"Left: {Configuration["App:MainWindow:Left"]}");
        Console.WriteLine();

        Console.WriteLine("Press a key...");
        Console.ReadKey();
    }
}

```

Running the code, the following output is displayed:

```

MachineName: MairaPC
Left: 1980

```

Passing argument key-value pairs on the command line changes the values of `Profile:MachineName` and `App:MainWindow:Left`:

```

dotnet run Profile:MachineName=BartPC App:MainWindow:Left=1979

```

The console window displays:

```

MachineName: BartPC
Left: 1979

```

To override configuration provided by other configuration providers with command-line configuration, call `AddCommandLine` last on `ConfigurationBuilder`:

```

var config = new ConfigurationBuilder()
    .SetBasePath(Directory.GetCurrentDirectory())
    .AddJsonFile("appsettings.json", optional: true, reloadOnChange: true)
    .AddEnvironmentVariables()
    .AddCommandLine(args)
    .Build();

```

## Arguments

Arguments passed on the command line must conform to one of two formats shown in the following table:

ARGUMENT FORMAT	EXAMPLE
Single argument: a key-value pair separated by an equals sign ( = )	key1=value
Sequence of two arguments: a key-value pair separated by a space	/key1 value1

### Single argument

The value must follow an equals sign ( = ). The value can be null (for example, mykey= ).

The key may have a prefix.

KEY PREFIX	EXAMPLE
No prefix	key1=value1
Single dash ( - )†	-key2=value2
Two dashes ( -- )	--key3=value3
Forward slash ( / )	/key4=value4

†A key with a single dash prefix ( - ) must be provided in [switch mappings](#), described below.

Example command:

```
dotnet run key1=value1 -key2=value2 --key3=value3 /key4=value4
```

Note: If -key2 isn't present in the [switch mappings](#) given to the configuration provider, a [FormatException](#) is thrown.

### Sequence of two arguments

The value can't be null and must follow the key separated by a space.

The key must have a prefix.

KEY PREFIX	EXAMPLE
Single dash ( - )†	-key1 value1
Two dashes ( -- )	--key2 value2
Forward slash ( / )	/key3 value3

†A key with a single dash prefix ( - ) must be provided in [switch mappings](#), described below.

Example command:

```
dotnet run -key1 value1 --key2 value2 /key3 value3
```

Note: If `-key1` isn't present in the [switch mappings](#) given to the configuration provider, a [FormatException](#) is thrown.

## Duplicate keys

If duplicate keys are provided, the last key-value pair is used.

## Switch mappings

When manually building configuration with [ConfigurationBuilder](#), a switch mappings dictionary can be added to the [AddCommandLine](#) method. Switch mappings allow key name replacement logic.

When the switch mappings dictionary is used, the dictionary is checked for a key that matches the key provided by a command-line argument. If the command-line key is found in the dictionary, the dictionary value (the key replacement) is passed back to set the configuration. A switch mapping is required for any command-line key prefixed with a single dash (`-`).

Switch mappings dictionary key rules:

- Switches must start with a dash (`-`) or double-dash (`--`).
- The switch mappings dictionary must not contain duplicate keys.

In the following example, the [GetSwitchMappings](#) method allows command-line arguments to use a single dash (`-`) key prefix and avoid leading subkey prefixes.

```

using System;
using System.Collections.Generic;
using System.Linq;
using Microsoft.Extensions.Configuration;

public class Program
{
    public static IConfiguration Configuration { get; set; }

    public static Dictionary<string, string> GetSwitchMappings(
        IReadOnlyDictionary<string, string> configurationStrings)
    {
        return configurationStrings.Select(item =>
            new KeyValuePair<string, string>(
                "-" + item.Key.Substring(item.Key.LastIndexOf(':') + 1),
                item.Key))
            .ToDictionary(
                item => item.Key, item => item.Value);
    }

    public static void Main(string[] args = null)
    {
        var dict = new Dictionary<string, string>
        {
            {"Profile:MachineName", "RickPC"},
            {"App:MainWindow:Left", "1980"}
        };

        var builder = new ConfigurationBuilder();

        builder.AddInMemoryCollection(dict)
            .AddCommandLine(args, GetSwitchMappings(dict));

        Configuration = builder.Build();

        Console.WriteLine($"MachineName: {Configuration["Profile:MachineName"]}");
        Console.WriteLine($"Left: {Configuration["App:MainWindow:Left"]}");
        Console.WriteLine();

        Console.WriteLine("Press a key...");
        Console.ReadKey();
    }
}

```

Without providing command-line arguments, the dictionary provided to `AddInMemoryCollection` sets the configuration values. Run the app with the following command:

```
dotnet run
```

The console window displays:

```
MachineName: RickPC
Left: 1980
```

Use the following to pass in configuration settings:

```
dotnet run /Profile:MachineName=DahliaPC /App:MainWindow:Left=1984
```

The console window displays:

```
MachineName: DahliaPC
Left: 1984
```

After the switch mappings dictionary is created, it contains the data shown in the following table:

KEY	VALUE
-MachineName	Profile:MachineName
-Left	App:MainWindow:Left

To demonstrate key switching using the dictionary, run the following command:

```
dotnet run -MachineName=ChadPC -Left=1988
```

The command-line keys are swapped. The console window displays the configuration values for `Profile:MachineName` and `App:MainWindow:Left`:

```
MachineName: ChadPC
Left: 1988
```

## web.config file

A `web.config` file is required when hosting the app in IIS or IIS Express. Settings in `web.config` enable the [ASP.NET Core Module](#) to launch the app and configure other IIS settings and modules. If the `web.config` file isn't present and the project file includes `<Project Sdk="Microsoft.NET.Sdk.Web">`, publishing the project creates a `web.config` file in the published output (the `publish` folder). For more information, see [Host ASP.NET Core on Windows with IIS](#).

## Access configuration during startup

To access configuration within `ConfigureServices` or `Configure` during startup, see the examples in the [Application startup](#) topic.

## Adding configuration from an external assembly

An [IHostingStartup](#) implementation allows adding enhancements to an app at startup from an external assembly outside of the app's `Startup` class. For more information, see [Enhance an app from an external assembly](#).

## Access configuration in a Razor Page or MVC view

To access configuration settings in a Razor Pages page or an MVC view, add a [using directive \(C# reference: using directive\)](#) for the [Microsoft.Extensions.Configuration](#) namespace and inject `IConfiguration` into the page or view.

In a Razor Pages page:

```

@page
@model IndexModel

@using Microsoft.Extensions.Configuration
@inject IConfiguration Configuration

<!DOCTYPE html>
<html lang="en">
<head>
    <title>Index Page</title>
</head>
<body>
    <h1>Access configuration in a Razor Pages page</h1>
    <p>Configuration["key"]: @Configuration["key"]</p>
</body>
</html>

```

In an MVC view:

```

@using Microsoft.Extensions.Configuration
@inject IConfiguration Configuration

<!DOCTYPE html>
<html lang="en">
<head>
    <title>Index View</title>
</head>
<body>
    <h1>Access configuration in an MVC view</h1>
    <p>Configuration["key"]: @Configuration["key"]</p>
</body>
</html>

```

## Additional notes

- Dependency Injection (DI) isn't set up until after `ConfigureServices` is invoked.
- The configuration system isn't DI aware.
- `IConfiguration` has two specializations:
  - `IConfigurationRoot` Used for the root node. Can trigger a reload.
  - `IConfigurationSection` Represents a section of configuration values. The `GetSection` and `GetChildren` methods return an `IConfigurationSection`.
- Use `IConfigurationRoot` when reloading configuration or for access to each provider. Neither of these situations are common.

# Options pattern in ASP.NET Core

7/11/2018 • 10 minutes to read • [Edit Online](#)

By [Luke Latham](#)

The options pattern uses classes to represent groups of related settings. When configuration settings are isolated by feature into separate classes, the app adheres to two important software engineering principles:

- The [Interface Segregation Principle \(ISP\)](#): Features (classes) that depend on configuration settings depend only on the configuration settings that they use.
- [Separation of Concerns](#): Settings for different parts of the app aren't dependent or coupled to one another.

[View or download sample code \(how to download\)](#) This article is easier to follow with the sample app.

## Basic options configuration

Basic options configuration is demonstrated as Example #1 in the [sample app](#).

An options class must be non-abstract with a public parameterless constructor. The following class, `MyOptions`, has two properties, `Option1` and `Option2`. Setting default values is optional, but the class constructor in the following example sets the default value of `option1`. `Option2` has a default value set by initializing the property directly (*Models/MyOptions.cs*):

```
public class MyOptions
{
    public MyOptions()
    {
        // Set default value.
        Option1 = "value1_from_ctor";
    }

    public string Option1 { get; set; }
    public int Option2 { get; set; } = 5;
}
```

The `MyOptions` class is added to the service container with `Configure<TOptions>(IServiceCollection, IConfiguration)` and bound to configuration:

```
// Example #1: Basic options
// Register the Configuration instance which MyOptions binds against.
services.Configure<MyOptions>(Configuration);
```

The following page model uses [constructor dependency injection](#) with `IOptions<TOptions>` to access the settings (*Pages/Index.cshtml.cs*):

```
private readonly MyOptions _options;
```

```
public IndexModel(
    IOptions<MyOptions> optionsAccessor,
    IOptions<MyOptionsWithDelegateConfig> optionsAccessorWithDelegateConfig,
    IOptions<MySubOptions> subOptionsAccessor,
    IOptionsSnapshot<MyOptions> snapshotOptionsAccessor,
    IOptionsSnapshot<MyOptions> namedOptionsAccessor)
{
    _options = optionsAccessor.Value;
    _optionsWithDelegateConfig = optionsAccessorWithDelegateConfig.Value;
    _subOptions = subOptionsAccessor.Value;
    _snapshotOptions = snapshotOptionsAccessor.Value;
    _named_options_1 = namedOptionsAccessor.Get("named_options_1");
    _named_options_2 = namedOptionsAccessor.Get("named_options_2");
}
```

```
// Example #1: Simple options
var option1 = _options.Option1;
var option2 = _options.Option2;
SimpleOptions = $"option1 = {option1}, option2 = {option2}";
```

The sample's `appsettings.json` file specifies values for `option1` and `option2`:

```
{
    "option1": "value1_from_json",
    "option2": -1,
    "subsection": {
        "suboption1": "subvalue1_from_json",
        "suboption2": 200
    },
    "Logging": {
        "LogLevel": {
            "Default": "Warning"
        }
    },
    "AllowedHosts": "*"
}
```

When the app is run, the page model's `OnGet` method returns a string showing the option class values:

```
option1 = value1_from_json, option2 = -1
```

#### NOTE

When using a custom [ConfigurationBuilder](#) to load options configuration from a settings file, confirm that the base path is set correctly:

```
var configBuilder = new ConfigurationBuilder()
    .SetBasePath(Directory.GetCurrentDirectory())
    .AddJsonFile("appsettings.json", optional: true);
var config = configBuilder.Build();

services.Configure<MyOptions>(config);
```

Explicitly setting the base path isn't required when loading options configuration from the settings file via [CreateDefaultBuilder](#).

## Configure simple options with a delegate

Configuring simple options with a delegate is demonstrated as Example #2 in the [sample app](#).

Use a delegate to set options values. The sample app uses the `MyOptionsWithDelegateConfig` class (`Models/MyOptionsWithDelegateConfig.cs`):

```
public class MyOptionsWithDelegateConfig
{
    public MyOptionsWithDelegateConfig()
    {
        // Set default value.
        Option1 = "value1_from_ctor";
    }

    public string Option1 { get; set; }
    public int Option2 { get; set; } = 5;
}
```

In the following code, a second `IConfigureOptions<TOptions>` service is added to the service container. It uses a delegate to configure the binding with `MyOptionsWithDelegateConfig`:

```
// Example #2: Options bound and configured by a delegate
services.Configure<MyOptionsWithDelegateConfig>(myOptions =>
{
    myOptions.Option1 = "value1_configured_by_delegate";
    myOptions.Option2 = 500;
});
```

*Index.cshtml.cs:*

```
private readonly MyOptionsWithDelegateConfig _optionsWithDelegateConfig;
```

```
public IndexModel(
    IOptions<MyOptions> optionsAccessor,
    IOptions<MyOptionsWithDelegateConfig> optionsAccessorWithDelegateConfig,
    IOptions<MySubOptions> subOptionsAccessor,
    IOptionsSnapshot<MyOptions> snapshotOptionsAccessor,
    IOptionsSnapshot<MyOptions> namedOptionsAccessor)
{
    _options = optionsAccessor.Value;
    _optionsWithDelegateConfig = optionsAccessorWithDelegateConfig.Value;
    _subOptions = subOptionsAccessor.Value;
    _snapshotOptions = snapshotOptionsAccessor.Value;
    _named_options_1 = namedOptionsAccessor.Get("named_options_1");
    _named_options_2 = namedOptionsAccessor.Get("named_options_2");
}
```

```
// Example #2: Options configured by delegate
var delegate_config_option1 = _optionsWithDelegateConfig.Option1;
var delegate_config_option2 = _optionsWithDelegateConfig.Option2;
SimpleOptionsWithDelegateConfig =
    $"delegate_option1 = {delegate_config_option1}, " +
    $"delegate_option2 = {delegate_config_option2}";
```

You can add multiple configuration providers. Configuration providers are available in NuGet packages. They're applied in order that they're registered.

Each call to `Configure<TOptions>` adds an `IConfigureOptions<TOptions>` service to the service container. In the preceding example, the values of `option1` and `option2` are both specified in `appsettings.json`, but the values of

`Option1` and `Option2` are overridden by the configured delegate.

When more than one configuration service is enabled, the last configuration source specified `wins` and sets the configuration value. When the app is run, the page model's `OnGet` method returns a string showing the option class values:

```
delegate_option1 = value1_configured_by_delegate, delegate_option2 = 500
```

## Suboptions configuration

Suboptions configuration is demonstrated as Example #3 in the [sample app](#).

Apps should create options classes that pertain to specific feature groups (classes) in the app. Parts of the app that require configuration values should only have access to the configuration values that they use.

When binding options to configuration, each property in the options type is bound to a configuration key of the form `property[:sub-property:]`. For example, the `MyOptions.Option1` property is bound to the key `Option1`, which is read from the `option1` property in `appsettings.json`.

In the following code, a third `IConfigureOptions<TOptions>` service is added to the service container. It binds `MySubOptions` to the section `subsection` of the `appsettings.json` file:

```
// Example #3: Sub-options
// Bind options using a sub-section of the appsettings.json file.
services.Configure<MySubOptions>(Configuration.GetSection("subsection"));
```

The `GetSection` extension method requires the [Microsoft.Extensions.Options.ConfigurationExtensions](#) NuGet package. If the app uses the [Microsoft.AspNetCore.App metapackage](#) (ASP.NET Core 2.1 or later), the package is automatically included.

The sample's `appsettings.json` file defines a `subsection` member with keys for `suboption1` and `suboption2`:

```
{
  "option1": "value1_from_json",
  "option2": -1,
  "subsection": {
    "suboption1": "subvalue1_from_json",
    "suboption2": 200
  },
  "Logging": {
    "LogLevel": {
      "Default": "Warning"
    }
  },
  "AllowedHosts": "*"
}
```

The `MySubOptions` class defines properties, `SubOption1` and `SubOption2`, to hold the sub-option values (`Models/MySubOptions.cs`):

```

public class MySubOptions
{
    public MySubOptions()
    {
        // Set default values.
        SubOption1 = "value1_from_ctor";
        SubOption2 = 5;
    }

    public string SubOption1 { get; set; }
    public int SubOption2 { get; set; }
}

```

The page model's `OnGet` method returns a string with the sub-option values (*Pages/Index.cshtml.cs*):

```
private readonly MySubOptions _subOptions;
```

```

public IndexModel(
    IOptions<MyOptions> optionsAccessor,
    IOptions<MyOptionsWithDelegateConfig> optionsAccessorWithDelegateConfig,
    IOptions<MySubOptions> subOptionsAccessor,
    IOptionsSnapshot<MyOptions> snapshotOptionsAccessor,
    IOptionsSnapshot<MyOptions> namedOptionsAccessor)
{
    _options = optionsAccessor.Value;
    _optionsWithDelegateConfig = optionsAccessorWithDelegateConfig.Value;
    _subOptions = subOptionsAccessor.Value;
    _snapshotOptions = snapshotOptionsAccessor.Value;
    _named_options_1 = namedOptionsAccessor.Get("named_options_1");
    _named_options_2 = namedOptionsAccessor.Get("named_options_2");
}

```

```

// Example #3: Sub-options
var subOption1 = _subOptions.SubOption1;
var subOption2 = _subOptions.SubOption2;
SubOptions = $"subOption1 = {subOption1}, subOption2 = {subOption2}";

```

When the app is run, the `OnGet` method returns a string showing the sub-option class values:

```
subOption1 = subvalue1_from_json, subOption2 = 200
```

## Options provided by a view model or with direct view injection

Options provided by a view model or with direct view injection is demonstrated as Example #4 in the [sample app](#).

Options can be supplied in a view model or by injecting `IOptions<TOptions>` directly into a view (*Pages/Index.cshtml.cs*):

```
private readonly MyOptions _options;
```

```
public IndexModel(
    IOptions<MyOptions> optionsAccessor,
    IOptions<MyOptionsWithDelegateConfig> optionsAccessorWithDelegateConfig,
    IOptions<MySubOptions> subOptionsAccessor,
    IOptionsSnapshot<MyOptions> snapshotOptionsAccessor,
    IOptionsSnapshot<MyOptions> namedOptionsAccessor)
{
    _options = optionsAccessor.Value;
    _optionsWithDelegateConfig = optionsAccessorWithDelegateConfig.Value;
    _subOptions = subOptionsAccessor.Value;
    _snapshotOptions = snapshotOptionsAccessor.Value;
    _named_options_1 = namedOptionsAccessor.Get("named_options_1");
    _named_options_2 = namedOptionsAccessor.Get("named_options_2");
}
```

```
// Example #4: Bind options directly to the page
MyOptions = _options;
```

For direct injection, inject `IOptions<MyOptions>` with an `@inject` directive:

```
@page
@model IndexModel
@using Microsoft.Extensions.Options
@using UsingOptionsSample.Models
@inject IOptions<MyOptions> OptionsAccessor
 @{
    ViewData["Title"] = "Using Options Sample";
}

<h1>@ViewData["Title"]</h1>
```

When the app is run, the option values are shown in the rendered page:

#### Example #4: Model and injected options

##### Options provided by the model

Options provided by the model: `@Model.MyOptions.Option1` and `@Model.MyOptions.Option2`

**Option1:** value1\_from\_json

**Option2:** -1

##### Options injected into the page

Options injected into the page: `@inject IOptions<MyOptions> OptionsAccessor` with `@OptionsAccessor.Value.Option1` and `@OptionsAccessor.Value.Option2`

**Option1:** value1\_from\_json

**Option2:** -1

## Reload configuration data with `IOptionsSnapshot`

Reloading configuration data with `IOptionsSnapshot` is demonstrated in Example #5 in the [sample app](#).

`IOptionsSnapshot` supports reloading options with minimal processing overhead.

Options are computed once per request when accessed and cached for the lifetime of the request.

`IOptionsSnapshot` is a snapshot of `IOptionsMonitor<TOptions>` and updates automatically whenever the monitor triggers changes based on the data source changing.

The following example demonstrates how a new `IOptionsSnapshot` is created after `appsettings.json` changes (`Pages/Index.cshtml.cs`). Multiple requests to the server return constant values provided by the `appsettings.json` file until the file is changed and configuration reloads.

```
private readonly MyOptions _snapshotOptions;

public IndexModel(
    IOptions<MyOptions> optionsAccessor,
    IOptions<MyOptionsWithDelegateConfig> optionsAccessorWithDelegateConfig,
    IOptions<MySubOptions> subOptionsAccessor,
    IOptionsSnapshot<MyOptions> snapshotOptionsAccessor,
    IOptionsSnapshot<MyOptions> namedOptionsAccessor)
{
    _options = optionsAccessor.Value;
    _optionsWithDelegateConfig = optionsAccessorWithDelegateConfig.Value;
    _subOptions = subOptionsAccessor.Value;
    _snapshotOptions = snapshotOptionsAccessor.Value;
    _named_options_1 = namedOptionsAccessor.Get("named_options_1");
    _named_options_2 = namedOptionsAccessor.Get("named_options_2");
}

// Example #5: Snapshot options
var snapshotOption1 = _snapshotOptions.Option1;
var snapshotOption2 = _snapshotOptions.Option2;
SnapshotOptions =
    $"snapshot option1 = {snapshotOption1}, " +
    $"snapshot option2 = {snapshotOption2}";
```

The following image shows the initial `option1` and `option2` values loaded from the `appsettings.json` file:

```
snapshot option1 = value1_from_json, snapshot option2 = -1
```

Change the values in the `appsettings.json` file to `value1_from_json UPDATED` and `200`. Save the `appsettings.json` file. Refresh the browser to see that the options values are updated:

```
snapshot option1 = value1_from_json UPDATED, snapshot option2 = 200
```

## Named options support with `IConfigureNamedOptions`

Named options support with `IConfigureNamedOptions` is demonstrated as Example #6 in the [sample app](#).

*Named options* support allows the app to distinguish between named options configurations. In the sample app, named options are declared with the `OptionsServiceCollectionExtensions.Configure<TOptions>(IServiceCollection, String, Action<TOptions>)` which in turn calls the extension method `ConfigureNamedOptions<TOptions>.Configure` method:

```

// Example #6: Named options (named_options_1)
// Register the ConfigurationBuilder instance which MyOptions binds against.
// Specify that the options loaded from configuration are named
// "named_options_1".
services.Configure<MyOptions>("named_options_1", Configuration);

// Example #6: Named options (named_options_2)
// Specify that the options loaded from the MyOptions class are named
// "named_options_2".
// Use a delegate to configure option values.
services.Configure<MyOptions>("named_options_2", myOptions =>
{
    myOptions.Option1 = "named_options_2_value1_from_action";
});

```

The sample app accesses the named options with [IOptionsSnapshot<TOptions>.Get \(Pages/Index.cshtml.cs\)](#):

```

private readonly MyOptions _named_options_1;
private readonly MyOptions _named_options_2;

```

```

public IndexModel(
    IOptions<MyOptions> optionsAccessor,
    IOptions<MyOptionsWithDelegateConfig> optionsAccessorWithDelegateConfig,
    IOptions<MySubOptions> subOptionsAccessor,
    IOptionsSnapshot<MyOptions> snapshotOptionsAccessor,
    IOptionsSnapshot<MyOptions> namedOptionsAccessor)
{
    _options = optionsAccessor.Value;
    _optionsWithDelegateConfig = optionsAccessorWithDelegateConfig.Value;
    _subOptions = subOptionsAccessor.Value;
    _snapshotOptions = snapshotOptionsAccessor.Value;
    _named_options_1 = namedOptionsAccessor.Get("named_options_1");
    _named_options_2 = namedOptionsAccessor.Get("named_options_2");
}

```

```

// Example #6: Named options
var named_options_1 =
    $"named_options_1: option1 = {_named_options_1.Option1}, " +
    $"option2 = {_named_options_1.Option2}";
var named_options_2 =
    $"named_options_2: option1 = {_named_options_2.Option1}, " +
    $"option2 = {_named_options_2.Option2}";
NamedOptions = $"{named_options_1} {named_options_2}";

```

Running the sample app, the named options are returned:

```

named_options_1: option1 = value1_from_json, option2 = -1
named_options_2: option1 = named_options_2_value1_from_action, option2 = 5

```

`named_options_1` values are provided from configuration, which are loaded from the *appsettings.json* file.  
`named_options_2` values are provided by:

- The `named_options_2` delegate in `ConfigureServices` for `Option1`.
- The default value for `Option2` provided by the `MyOptions` class.

Configure all named options instances with the [OptionsServiceCollectionExtensions.ConfigureAll](#) method. The following code configures `Option1` for all named configuration instances with a common value. Add the

following code manually to the `Configure` method:

```
services.ConfigureAll<MyOptions>(myOptions =>
{
    myOptions.Option1 = "ConfigureAll replacement value";
});
```

Running the sample app after adding the code produces the following result:

```
named_options_1: option1 = ConfigureAll replacement value, option2 = -1
named_options_2: option1 = ConfigureAll replacement value, option2 = 5
```

#### NOTE

All options are named instances. Existing `IConfigureOption` instances are treated as targeting the `Options.DefaultName` instance, which is `string.Empty`. `IConfigureNamedOptions` also implements `IConfigureOptions`. The default implementation of the `IOptionsFactory<TOptions>` ([reference source](#)) has logic to use each appropriately. The `null` named option is used to target all of the named instances instead of a specific named instance (`ConfigureAll` and `PostConfigureAll` use this convention).

## IPostConfigureOptions

Set postconfiguration with `IPostConfigureOptions<TOptions>`. Postconfiguration runs after all `IConfigureOptions<TOptions>` configuration occurs:

```
services.PostConfigure<MyOptions>(myOptions =>
{
    myOptions.Option1 = "post_configured_option1_value";
});
```

`PostConfigure<TOptions>` is available to post-configure named options:

```
services.PostConfigure<MyOptions>("named_options_1", myOptions =>
{
    myOptions.Option1 = "post_configured_option1_value";
});
```

Use `PostConfigureAll<TOptions>` to post-configure all named configuration instances:

```
services.PostConfigureAll<MyOptions>("named_options_1", myOptions =>
{
    myOptions.Option1 = "post_configured_option1_value";
});
```

## Options factory, monitoring, and cache

`IOptionsMonitor` is used for notifications when `TOptions` instances change. `IOptionsMonitor` supports reloadable options, change notifications, and `IPostConfigureOptions`.

`IOptionsFactory<TOptions>` is responsible for creating new options instances. It has a single `Create` method. The default implementation takes all registered `IConfigureOptions` and `IPostConfigureOptions` and runs all the configures first, followed by the post-configures. It distinguishes between `IConfigureNamedOptions` and

`IConfigureOptions` and only calls the appropriate interface.

`IOptionsMonitorCache<TOptions>` is used by `IOptionsMonitor` to cache `TOptions` instances. The `IOptionsMonitorCache` invalidates options instances in the monitor so that the value is recomputed (`TryRemove`). Values can be manually introduced as well with `TryAdd`. The `Clear` method is used when all named instances should be recreated on demand.

## Accessing options during startup

`IOptions` can be used in `Configure`, since services are built before the `Configure` method executes. If a service provider is built in `ConfigureServices` to access options, it wouldn't contain any options configurations provided after the service provider is built. Therefore, an inconsistent options state may exist due to the ordering of service registrations.

Since options are typically loaded from configuration, configuration can be used in startup in both `Configure` and `ConfigureServices`. For examples of using configuration during startup, see the [Application startup](#) topic.

# Enhance an app from an external assembly in ASP.NET Core with IHostingStartup

6/21/2018 • 5 minutes to read • [Edit Online](#)

By [Luke Latham](#)

An [IHostingStartup](#) implementation allows adding enhancements to an app at startup from an external assembly outside of the app's `Startup` class. For example, an external tooling library can use an `IHostingStartup` implementation to provide additional configuration providers or services to an app. `IHostingStartup` is available in ASP.NET Core 2.0 and later.

[View or download sample code \(how to download\)](#)

## Discover loaded hosting startup assemblies

To discover hosting startup assemblies loaded by the app or by libraries, enable logging and check the application logs. Errors that occur when loading assemblies are logged. Loaded hosting startup assemblies are logged at the Debug level, and all errors are logged.

The sample app reads the `HostingStartupAssembliesKey` into a `string` array and displays the result in the app's Index page:

```
public class IndexModel : PageModel
{
    private readonly IConfiguration _config;

    public IndexModel(IConfiguration config)
    {
        _config = config;
    }

    public string[] LoadedHostingStartupAssemblies { get; private set; }

    public void OnGet()
    {
        LoadedHostingStartupAssemblies =
            _config[WebHostDefaults.HostingStartupAssembliesKey]
            .Split(new[] { ';' }, StringSplitOptions.RemoveEmptyEntries) ?? new string[0];
    }
}
```

## Disable automatic loading of hosting startup assemblies

There are two ways to disable the automatic loading of hosting startup assemblies:

- Set the [Prevent Hosting Startup](#) host configuration setting.
- Set the `ASPNETCORE_PREVENTHOSTINGSTARTUP` environment variable.

When either the host setting or the environment variable is set to `true` or `1`, hosting startup assemblies aren't automatically loaded. If both are set, the host setting controls the behavior.

Disabling hosting startup assemblies using the host setting or environment variable disables them globally and may disable several characteristics of an app. It isn't currently possible to selectively disable a hosting startup

assembly added by a library unless the library offers its own configuration option. A future release will offer the ability to selectively disable hosting startup assemblies (see [GitHub issue aspnet/Hosting #1243](#)).

## Implement IHostingStartup

### Create the assembly

An `IHostingStartup` enhancement is deployed as an assembly based on a console app without an entry point. The assembly references the `Microsoft.AspNetCore.Hosting.Abstractions` package:

```
<Project Sdk="Microsoft.NET.Sdk">

<PropertyGroup>
  <TargetFramework>netcoreapp2.1</TargetFramework>
</PropertyGroup>

<ItemGroup>
  <PackageReference Include="Microsoft.AspNetCore.Hosting.Abstractions"
    Version="2.1.0" />
</ItemGroup>

</Project>
```

A `HostingStartup` attribute identifies a class as an implementation of `IHostingStartup` for loading and execution when building the `IWebHost`. In the following example, the namespace is `StartupEnhancement`, and the class is `StartupEnhancementHostingStartup`:

```
[assembly: HostingStartup(typeof(StartupEnhancement.StartupEnhancementHostingStartup))]
```

A class implements `IHostingStartup`. The class's `Configure` method uses an `IWebHostBuilder` to add enhancements to an app. `IHostingStartup.Configure` in the hosting startup assembly is called by the runtime before `Startup.Configure` in user code, which allows user code to overwrite any configuration provided by the hosting startup assembly.

```
namespace StartupEnhancement
{
    public class StartupEnhancementHostingStartup : IHostingStartup
    {
        public void Configure(IWebHostBuilder builder)
        {
            // Use the IWebHostBuilder to add app enhancements.
        }
    }
}
```

When building an `IHostingStartup` project, the dependencies file (`*.deps.json`) sets the `runtime` location of the assembly to the `bin` folder:

```
"targets": {
  ".NETCoreApp,Version=v2.1": {
    "StartupEnhancement/1.0.0": {
      "dependencies": {
        "Microsoft.AspNetCore.Hosting.Abstractions": "2.1.0"
      },
      "runtime": {
        "StartupEnhancement.dll": {}
      }
    }
  }
}
```

Only part of the file is shown. The assembly name in the example is `StartupEnhancement`.

## Update the dependencies file

The runtime location is specified in the `*.deps.json` file. To active the enhancement, the `runtime` element must specify the location of the enhancement's runtime assembly. Prefix the `runtime` location with

```
lib/<TARGET_FRAMEWORK_MONIKER> :
```

```
"targets": {
  ".NETCoreApp,Version=v2.1": {
    "StartupEnhancement/1.0.0": {
      "dependencies": {
        "Microsoft.AspNetCore.Hosting.Abstractions": "2.1.0"
      },
      "runtime": {
        "lib/netcoreapp2.1/StartupEnhancement.dll": {}
      }
    }
  }
}
```

In the sample app, modification of the `*.deps.json` file is performed by a [PowerShell](#) script. The PowerShell script is automatically triggered by a build target in the project file.

## Enhancement activation

### Place the assembly file

The `IHostingStartup` implementation's assembly file must be *bin*-deployed in the app or placed in the [runtime store](#):

For per-user use, place the assembly in the user profile's runtime store at:

```
<DRIVE>\Users\<USER>\.dotnet\store\x64\<TARGET_FRAMEWORK_MONIKER>\<ENHANCEMENT_ASSEMBLY_NAME>\  
<ENHANCEMENT_VERSION>\lib\<TARGET_FRAMEWORK_MONIKER>\
```

For global use, place the assembly in the .NET Core installation's runtime store:

```
<DRIVE>\Program Files\dotnet\store\x64\<TARGET_FRAMEWORK_MONIKER>\<ENHANCEMENT_ASSEMBLY_NAME>\  
<ENHANCEMENT_VERSION>\lib\<TARGET_FRAMEWORK_MONIKER>\
```

When deploying the assembly to the runtime store, the symbols file may be deployed as well but isn't required for the enhancement to work.

### Place the dependencies file

The implementation's `*.deps.json` file must be in an accessible location.

For per-user use, place the file in the `additionalDeps` folder of the user profile's `.dotnet` settings:

```
<DRIVE>\Users\<USER>\.dotnet\x64\additionalDeps\<ENHANCEMENT_ASSEMBLY_NAME>\shared\Microsoft.NETCore.App\  
<SHARED_FRAMEWORK_VERSION>\
```

For global use, place the file in the `additionalDeps` folder of the .NET Core installation:

```
<DRIVE>\Program Files\dotnet\additionalDeps\<ENHANCEMENT_ASSEMBLY_NAME>\shared\Microsoft.NETCore.App\  
<SHARED_FRAMEWORK_VERSION>\
```

The shared framework version reflects the version of the shared runtime that the target app uses. The shared runtime is shown in the `*.runtimeconfig.json` file. In the sample app, the shared runtime is specified in the `HostingStartupSample.runtimeconfig.json` file.

### Set environment variables

Set the following environment variables in the context of the app that uses the enhancement.

#### ASPNETCORE\_HOSTINGSTARTUPASSEMBLIES

Only hosting startup assemblies are scanned for the `HostingStartupAttribute`. The assembly name of the implementation is provided in this environment variable. The sample app sets this value to `StartupDiagnostics`.

The value can also be set using the [Hosting Startup Assemblies](#) host configuration setting.

When multiple hosting startup assemblies are present, their `Configure` methods are executed in the order that the assemblies are listed.

#### DOTNET\_ADDITIONAL\_DEPS

The location of the implementation's `*.deps.json` file.

If the file is placed in the user profile's `.dotnet` folder for per-user use:

```
<DRIVE>\Users\<USER>\.dotnet\x64\additionalDeps\
```

If the file is placed in the .NET Core installation for global use, provide the full path to the file:

```
<DRIVE>\Program Files\dotnet\additionalDeps\<ENHANCEMENT_ASSEMBLY_NAME>\shared\Microsoft.NETCore.App\  
<SHARED_FRAMEWORK_VERSION>\<ENHANCEMENT_ASSEMBLY_NAME>.deps.json
```

The sample app sets this value to:

```
%UserProfile%\dotnet\x64\additionalDeps\StartupDiagnostics\
```

For examples of how to set environment variables for various operating systems, see [Use multiple environments](#).

## Sample app

The [sample app \(how to download\)](#) uses `IHostingStartup` to create a diagnostics tool. The tool adds two middlewares to the app at startup that provide diagnostic information:

- Registered services
- Address: scheme, host, path base, path, query string
- Connection: remote IP, remote port, local IP, local port, client certificate

- Request headers
- Environment variables

To run the sample:

1. The Startup Diagnostic project uses [PowerShell](#) to modify its `StartupDiagnostics.deps.json` file. PowerShell is installed by default on Windows OS starting with Windows 7 SP1 and Windows Server 2008 R2 SP1. To obtain PowerShell on other platforms, see [Installing Windows PowerShell](#).
2. Build the Startup Diagnostic project. A build target in the project file:
  - Moves the assembly and symbols files to the user profile's runtime store.
  - Triggers the PowerShell script to modify the `StartupDiagnostics.deps.json` file.
  - Moves the `StartupDiagnostics.deps.json` file to the user profile's `additionalDeps` folder.
3. Set the environment variables:
  - `ASPNETCORE_HOSTINGSTARTUPASSEMBLIES` : `StartupDiagnostics`
  - `DOTNET_ADDITIONAL_DEPS` : `%UserProfile%\dotnet\x64\additionalDeps\StartupDiagnostics\`
4. Run the sample app.
5. Request the `/services` endpoint to see the app's registered services. Request the `/diag` endpoint to see the diagnostic information.

# Logging in ASP.NET Core

7/10/2018 • 23 minutes to read • [Edit Online](#)

By [Steve Smith](#) and [Tom Dykstra](#)

ASP.NET Core supports a logging API that works with a variety of logging providers. Built-in providers let you send logs to one or more destinations, and you can plug in a third-party logging framework. This article shows how to use the built-in logging API and providers in your code.

[View or download sample code \(how to download\)](#)

[View or download sample code \(how to download\)](#)

For information on stdout logging when hosting with IIS, see [Troubleshoot ASP.NET Core on IIS](#). For information on stdout logging with Azure App Service, see [Troubleshoot ASP.NET Core on Azure App Service](#).

## How to create logs

To create logs, implement an [ILogger](#) object from the [dependency injection container](#):

```
public class TodoController : Controller
{
    private readonly ITodoRepository _todoRepository;
    private readonly ILogger _logger;

    public TodoController(ITodoRepository todoRepository,
        ILogger<TodoController> logger)
    {
        _todoRepository = todoRepository;
        _logger = logger;
    }
}
```

Then call logging methods on that logger object:

```
public IActionResult GetById(string id)
{
    _logger.LogInformation(LoggingEvents.GetItem, "Getting item {ID}", id);
    var item = _todoRepository.Find(id);
    if (item == null)
    {
        _logger.LogWarning(LoggingEvents.GetItemNotFound, "GetById({ID}) NOT FOUND", id);
        return NotFound();
    }
    return new ObjectResult(item);
}
```

This example creates logs with the `TodoController` class as the *category*. Categories are explained [later in this article](#).

ASP.NET Core doesn't provide async logger methods because logging should be so fast that it isn't worth the cost of using async. If you're in a situation where that's not true, consider changing the way you log. If your data store is slow, write the log messages to a fast store first, then move them to a slow store later. For example, log to a message queue that's read and persisted to slow storage by another process.

## How to add providers

A logging provider takes the messages that you create with an `ILogger` object and displays or stores them. For example, the Console provider displays messages on the console, and the Azure App Service provider can store them in Azure blob storage.

To use a provider, call the provider's `Add<ProviderName>` extension method in *Program.cs*:

```
public static void Main(string[] args)
{
    var webHost = new WebHostBuilder()
        .UseKestrel()
        .UseContentRoot(Directory.GetCurrentDirectory())
        .ConfigureAppConfiguration((hostingContext, config) =>
    {
        var env = hostingContext.HostingEnvironment;
        config.AddJsonFile("appsettings.json", optional: true, reloadOnChange: true)
            .AddJsonFile($"appsettings.{env.EnvironmentName}.json", optional: true, reloadOnChange:
true);
        config.AddEnvironmentVariables();
    })
        .ConfigureLogging((hostingContext, logging) =>
    {
        logging.AddConfiguration(hostingContext.Configuration.GetSection("Logging"));
        logging.AddConsole();
        logging.AddDebug();
    })
        .UseStartup<Startup_()
        .Build();

    webHost.Run();
}
```

The default project template enables logging with the [CreateDefaultBuilder](#) method:

```
public static void Main(string[] args)
{
    BuildWebHost(args).Run();
}

public static IWebHost BuildWebHost(string[] args) =>
    WebHost.CreateDefaultBuilder(args)
        .UseStartup<Startup_()
        .Build();
```

A logging provider takes the messages that you create with an `ILogger` object and displays or stores them. For example, the Console provider displays messages on the console, and the Azure App Service provider can store them in Azure blob storage.

To use a provider, install its NuGet package and call the provider's extension method on an instance of `ILoggerFactory`, as shown in the following example:

```
public void Configure(IApplicationBuilder app,
    IHostingEnvironment env,
    ILoggerFactory loggerFactory)
{
    loggerFactory
        .AddConsole()
        .AddDebug();
```

ASP.NET Core dependency injection (DI) provides the `I LoggerFactory` instance. The `AddConsole` and `AddDebug` extension methods are defined in the `Microsoft.Extensions.Logging.Console` and `Microsoft.Extensions.Logging.Debug` packages. Each extension method calls the `I LoggerFactory.AddProvider` method, passing in an instance of the provider.

**NOTE**

The [sample app](#) adds logging providers in the `Startup.Configure` method. If you want to obtain log output from code that executes earlier, add logging providers in the `Startup` class constructor.

You'll find information about each [built-in logging provider](#) and links to [third-party logging providers](#) later in the article.

## Settings file configuration

Each of the preceding examples in the [How to add providers](#) section loads logging provider configuration from the `Logging` section of app settings files. The following example shows the contents of a typical `appsettings.Development.json` file:

```
{  
  "Logging": {  
    "LogLevel": {  
      "Default": "Debug",  
      "System": "Information",  
      "Microsoft": "Information"  
    },  
    "Console": {  
      "IncludeScopes": "true"  
    }  
  }  
}
```

`LogLevel` keys represent log names. The `Default` key applies to logs not explicitly listed. The value represents the [log level](#) applied to the given log. Log keys that set `IncludeScopes` (`Console` in the example), specify if [log scopes](#) are enabled for the indicated log.

```
{  
  "Logging": {  
    "LogLevel": {  
      "Default": "Debug",  
      "System": "Information",  
      "Microsoft": "Information"  
    }  
  }  
}
```

`LogLevel` keys represent log names. The `Default` key applies to logs not explicitly listed. The value represents the [log level](#) applied to the given log.

## Sample logging output

With the sample code shown in the preceding section, you'll see logs in the console when you run from the command line. Here's an example of console output:

```
info: Microsoft.AspNetCore.Hosting.Internal.WebHost[1]
      Request starting HTTP/1.1 GET http://localhost:5000/api/todo/0
info: Microsoft.AspNetCore.Mvc.Internal.ControllerActionInvoker[1]
      Executing action method TodoApi.Controllers.TodoController.GetById (TodoApi) with arguments (0) -
ModelState is Valid
info: TodoApi.Controllers.TodoController[1002]
      Getting item 0
warn: TodoApi.Controllers.TodoController[4000]
      GetById(0) NOT FOUND
info: Microsoft.AspNetCore.Mvc.StatusCodeResult[1]
      Executing HttpStatusCodeResult, setting HTTP status code 404
info: Microsoft.AspNetCore.Mvc.Internal.ControllerActionInvoker[2]
      Executed action TodoApi.Controllers.TodoController.GetById (TodoApi) in 42.9286ms
info: Microsoft.AspNetCore.Hosting.Internal.WebHost[2]
      Request finished in 148.889ms 404
```

These logs were created by going to `http://localhost:5000/api/todo/0`, which triggers execution of both `ILogger` calls shown in the preceding section.

Here's an example of the same logs as they appear in the Debug window when you run the sample application in Visual Studio:

```
Microsoft.AspNetCore.Hosting.Internal.WebHost:Information: Request starting HTTP/1.1 GET
http://localhost:53104/api/todo/0
Microsoft.AspNetCore.Mvc.Internal.ControllerActionInvoker:Information: Executing action method
TodoApi.Controllers.TodoController.GetById (TodoApi) with arguments (0) - ModelState is Valid
TodoApi.Controllers.TodoController:Information: Getting item 0
TodoApi.Controllers.TodoController:Warning: GetById(0) NOT FOUND
Microsoft.AspNetCore.Mvc.StatusCodeResult:Information: Executing HttpStatusCodeResult, setting HTTP status
code 404
Microsoft.AspNetCore.Mvc.Internal.ControllerActionInvoker:Information: Executed action
TodoApi.Controllers.TodoController.GetById (TodoApi) in 152.5657ms
Microsoft.AspNetCore.Hosting.Internal.WebHost:Information: Request finished in 316.3195ms 404
```

The logs that were created by the `ILogger` calls shown in the preceding section begin with "TodoApi.Controllers.TodoController". The logs that begin with "Microsoft" categories are from ASP.NET Core. ASP.NET Core itself and your application code are using the same logging API and the same logging providers.

The remainder of this article explains some details and options for logging.

## NuGet packages

The `ILogger` and `ILoggerFactory` interfaces are in [Microsoft.Extensions.Logging.Abstractions](#), and default implementations for them are in [Microsoft.Extensions.Logging](#).

## Log category

A *category* is included with each log that you create. You specify the category when you create an `ILogger` object. The category may be any string, but a convention is to use the fully qualified name of the class from which the logs are written. For example: "TodoApi.Controllers.TodoController".

You can specify the category as a string or use an extension method that derives the category from the type. To specify the category as a string, call `CreateLogger` on an `ILoggerFactory` instance, as shown below.

```

public class TodoController : Controller
{
    private readonly ITodoRepository _todoRepository;
    private readonly ILogger _logger;

    public TodoController(ITodoRepository todoRepository,
        ILoggerFactory logger)
    {
        _todoRepository = todoRepository;
        _logger = logger.CreateLogger("TodoApi.Controllers.TodoController");
    }
}

```

Most of the time, it will be easier to use `ILogger<T>`, as in the following example.

```

public class TodoController : Controller
{
    private readonly ITodoRepository _todoRepository;
    private readonly ILogger _logger;

    public TodoController(ITodoRepository todoRepository,
        ILogger<TodoController> logger)
    {
        _todoRepository = todoRepository;
        _logger = logger;
    }
}

```

This is equivalent to calling `CreateLogger` with the fully qualified type name of `T`.

## Log level

Each time you write a log, you specify its [LogLevel](#). The log level indicates the degree of severity or importance. For example, you might write an `Information` log when a method ends normally, a `Warning` log when a method returns a 404 return code, and an `Error` log when you catch an unexpected exception.

In the following code example, the names of the methods (for example, `LogWarning`) specify the log level. The first parameter is the [Log event ID](#). The second parameter is a [message template](#) with placeholders for argument values provided by the remaining method parameters. The method parameters are explained in more detail later in this article.

```

public IActionResult GetById(string id)
{
    _logger.LogInformation(LoggingEvents.GetItem, "Getting item {ID}", id);
    var item = _todoRepository.Find(id);
    if (item == null)
    {
        _logger.LogWarning(LoggingEvents.GetItemNotFound, "GetById({ID}) NOT FOUND", id);
        return NotFound();
    }
    return new ObjectResult(item);
}

```

Log methods that include the level in the method name are [extension methods for ILogger](#). Behind the scenes, these methods call a `Log` method that takes a `LogLevel` parameter. You can call the `Log` method directly rather than one of these extension methods, but the syntax is relatively complicated. For more information, see the [ILogger interface](#) and the [logger extensions source code](#).

ASP.NET Core defines the following [log levels](#), ordered here from least to highest severity.

- Trace = 0

For information that's valuable only to a developer debugging an issue. These messages may contain sensitive application data and so shouldn't be enabled in a production environment. *Disabled by default*.

Example: `credentials: {"User": "someuser", "Password": "P@ssword"}`

- Debug = 1

For information that has short-term usefulness during development and debugging. Example:

`Entering method Configure with flag set to true.` You typically wouldn't enable `Debug` level logs in production unless you are troubleshooting, due to the high volume of logs.

- Information = 2

For tracking the general flow of the application. These logs typically have some long-term value. Example:

`Request received for path /api/todo`

- Warning = 3

For abnormal or unexpected events in the application flow. These may include errors or other conditions that don't cause the application to stop, but which may need to be investigated. Handled exceptions are a common place to use the `Warning` log level. Example: `FileNotFoundException for file quotes.txt.`

- Error = 4

For errors and exceptions that cannot be handled. These messages indicate a failure in the current activity or operation (such as the current HTTP request), not an application-wide failure. Example log message:

`Cannot insert record due to duplicate key violation.`

- Critical = 5

For failures that require immediate attention. Examples: data loss scenarios, out of disk space.

You can use the log level to control how much log output is written to a particular storage medium or display window. For example, in production you might want all logs of `Information` level and lower to go to a volume data store, and all logs of `Warning` level and higher to go to a value data store. During development, you might normally send logs of `Warning` or higher severity to the console. Then when you need to troubleshoot, you can add `Debug` level. The [Log filtering](#) section later in this article explains how to control which log levels a provider handles.

The ASP.NET Core framework writes `Debug` level logs for framework events. The log examples earlier in this article excluded logs below `Information` level, so no `Debug` level logs were shown. Here's an example of console logs if you run the sample application configured to show `Debug` and higher logs for the console provider.

```

info: Microsoft.AspNetCore.Hosting.Internal.WebHost[1]

info: Microsoft.AspNetCore.Hosting.Internal.WebHost[2]
      Request finished in 2.7286ms 404

```

## Log event ID

Each time you write a log, you can specify an *event ID*. The sample app does this by using a locally-defined `LoggingEvents` class:

```

public IActionResult GetById(string id)
{
    _logger.LogInformation(LoggingEvents.GetItem, "Getting item {ID}", id);
    var item = _todoRepository.Find(id);
    if (item == null)
    {
        _logger.LogWarning(LoggingEvents.GetItemNotFound, ".GetById({ID}) NOT FOUND", id);
        return NotFound();
    }
    return new ObjectResult(item);
}

```

```

public class LoggingEvents
{
    public const int GenerateItems = 1000;
    public const int ListItems = 1001;
    public const int GetItem = 1002;
    public const int InsertItem = 1003;
    public const int UpdateItem = 1004;
    public const int DeleteItem = 1005;

    public const int GetItemNotFound = 4000;
    public const int UpdateItemNotFound = 4001;
}

```

An event ID is an integer value that you can use to associate a set of logged events with one another. For instance, a log for adding an item to a shopping cart could be event ID 1000 and a log for completing a purchase could be event ID 1001.

In logging output, the event ID may be stored in a field or included in the text message, depending on the provider. The Debug provider doesn't show event IDs, but the console provider shows them in brackets after the category:

```
info: TodoApi.Controllers.TodoController[1002]
      Getting item invalidid
warn: TodoApi.Controllers.TodoController[4000]
      GetById(invalidid) NOT FOUND
```

## Log message template

Each time you write a log message, you provide a message template. The message template can be a string or it can contain named placeholders into which argument values are placed. The template isn't a format string, and placeholders should be named, not numbered.

```
public IActionResult GetById(string id)
{
    _logger.LogInformation(LoggingEvents.GetItem, "Getting item {ID}", id);
    var item = _todoRepository.Find(id);
    if (item == null)
    {
        _logger.LogWarning(LoggingEvents.GetItemNotFound, "GetById({ID}) NOT FOUND", id);
        return NotFound();
    }
    return new ObjectResult(item);
}
```

The order of placeholders, not their names, determines which parameters are used to provide their values. If you have the following code:

```
string p1 = "parm1";
string p2 = "parm2";
_logger.LogInformation("Parameter values: {p2}, {p1}", p1, p2);
```

The resulting log message looks like this:

```
Parameter values: parm1, parm2
```

The logging framework does message formatting in this way to make it possible for logging providers to implement [semantic logging, also known as structured logging](#). Because the arguments themselves are passed to the logging system, not just the formatted message template, logging providers can store the parameter values as fields in addition to the message template. If you're directing your log output to Azure Table Storage and your logger method call looks like this:

```
_logger.LogInformation("Getting item {ID} at {RequestTime}", id, DateTime.Now);
```

Each Azure Table entity can have `ID` and `RequestTime` properties, which simplifies queries on log data. You can find all logs within a particular `RequestTime` range without the need to parse the time out of the text message.

# Logging exceptions

The logger methods have overloads that let you pass in an exception, as in the following example:

```
catch (Exception ex)
{
    _logger.LogWarning(LoggingEvents.GetItemNotFound, ex, "GetById({ID}) NOT FOUND", id);
    return NotFound();
}
return new ObjectResult(item);
```

Different providers handle the exception information in different ways. Here's an example of Debug provider output from the code shown above.

```
TodoApi.Controllers.TodoController:Warning: GetById(036dd898-fb01-47e8-9a65-f92eb73cf924) NOT FOUND
System.Exception: Item not found exception.
at TodoApi.Controllers.TodoController.GetById(String id) in
C:\logging\sample\src\TodoApi\Controllers\TodoController.cs:line 226
```

## Log filtering

You can specify a minimum log level for a specific provider and category or for all providers or all categories. Any logs below the minimum level aren't passed to that provider, so they don't get displayed or stored.

If you want to suppress all logs, you can specify `LogLevel.None` as the minimum log level. The integer value of `LogLevel.None` is 6, which is higher than `LogLevel.Critical` (5).

### Create filter rules in configuration

The project templates create code that calls `CreateDefaultBuilder` to set up logging for the Console and Debug providers. The `CreateDefaultBuilder` method also sets up logging to look for configuration in a `Logging` section, using code like the following:

```
public static void Main(string[] args)
{
    var webHost = new WebHostBuilder()
        .UseKestrel()
        .UseContentRoot(Directory.GetCurrentDirectory())
        .ConfigureAppConfiguration((hostingContext, config) =>
    {
        var env = hostingContext.HostingEnvironment;
        config.AddJsonFile("appsettings.json", optional: true, reloadOnChange: true)
            .AddJsonFile($"appsettings.{env.EnvironmentName}.json", optional: true, reloadOnChange:
true);
        config.AddEnvironmentVariables();
    })
    .ConfigureLogging((hostingContext, logging) =>
    {
        logging.AddConfiguration(hostingContext.Configuration.GetSection("Logging"));
        logging.AddConsole();
        logging.AddDebug();
    })
    .UseStartup<Startup>()
    .Build();

    webHost.Run();
}
```

The configuration data specifies minimum log levels by provider and category, as in the following example:

```
{  
    "Logging": {  
        "Debug": {  
            "LogLevel": {  
                "Default": "Information"  
            }  
        },  
        "Console": {  
            "IncludeScopes": false,  
            "LogLevel": {  
                "Microsoft.AspNetCore.Mvc.Razor.Internal": "Warning",  
                "Microsoft.AspNetCore.Mvc.Razor.Razor": "Debug",  
                "Microsoft.AspNetCore.Mvc.Razor": "Error",  
                "Default": "Information"  
            }  
        },  
        "LogLevel": {  
            "Default": "Debug"  
        }  
    }  
}
```

This JSON creates six filter rules, one for the Debug provider, four for the Console provider, and one that applies to all providers. You'll see later how just one of these rules is chosen for each provider when an `ILogger` object is created.

## Filter rules in code

You can register filter rules in code, as shown in the following example:

```
WebHost.CreateDefaultBuilder(args)  
    .UseStartup<Startup>()  
    .ConfigureLogging(logging =>  
        logging.AddFilter("System", LogLevel.Debug)  
            .AddFilter<DebugLoggerProvider>("Microsoft", LogLevel.Trace))  
    .Build();
```

The second `AddFilter` specifies the Debug provider by using its type name. The first `AddFilter` applies to all providers because it doesn't specify a provider type.

## How filtering rules are applied

The configuration data and the `AddFilter` code shown in the preceding examples create the rules shown in the following table. The first six come from the configuration example and the last two come from the code example.

NUMBER	PROVIDER	CATEGORIES THAT BEGIN WITH ...	MINIMUM LOG LEVEL
1	Debug	All categories	Information
2	Console	Microsoft.AspNetCore.Mvc.Razor.Internal	Warning
3	Console	Microsoft.AspNetCore.Mvc.Razor.Razor	Debug

NUMBER	PROVIDER	CATEGORIES THAT BEGIN WITH ...	MINIMUM LOG LEVEL
4	Console	Microsoft.AspNetCore.Mvc.Razor	Error
5	Console	All categories	Information
6	All providers	All categories	Debug
7	All providers	System	Debug
8	Debug	Microsoft	Trace

When you create an `ILogger` object to write logs with, the `ILoggerFactory` object selects a single rule per provider to apply to that logger. All messages written by that `ILogger` object are filtered based on the selected rules. The most specific rule possible for each provider and category pair is selected from the available rules.

The following algorithm is used for each provider when an `ILogger` is created for a given category:

- Select all rules that match the provider or its alias. If none are found, select all rules with an empty provider.
- From the result of the preceding step, select rules with longest matching category prefix. If none are found, select all rules that don't specify a category.
- If multiple rules are selected take the **last** one.
- If no rules are selected, use `MinimumLevel`.

For example, suppose you have the preceding list of rules and you create an `ILogger` object for category "Microsoft.AspNetCore.Mvc.Razor.RazorViewEngine":

- For the Debug provider, rules 1, 6, and 8 apply. Rule 8 is most specific, so that's the one selected.
- For the Console provider, rules 3, 4, 5, and 6 apply. Rule 3 is most specific.

When you create logs with an `ILogger` for category "Microsoft.AspNetCore.Mvc.Razor.RazorViewEngine", logs of `Trace` level and above will go to the Debug provider, and logs of `Debug` level and above will go to the Console provider.

## Provider aliases

You can use the type name to specify a provider in configuration, but each provider defines a shorter *alias* that's easier to use. For the built-in providers, use the following aliases:

- Console
- Debug
- EventLog
- AzureAppServices
- TraceSource
- EventSource

## Default minimum level

There's a minimum level setting that takes effect only if no rules from configuration or code apply for a given provider and category. The following example shows how to set the minimum level:

```
WebHost.CreateDefaultBuilder(args)
    .UseStartup<Startup>()
    .ConfigureLogging(logging => logging.SetMinimumLevel(LogLevel.Warning))
    .Build();
```

If you don't explicitly set the minimum level, the default value is `Information`, which means that `Trace` and `Debug` logs are ignored.

## Filter functions

You can write code in a filter function to apply filtering rules. A filter function is invoked for all providers and categories that don't have rules assigned to them by configuration or code. Code in the function has access to the provider type, category, and log level to decide whether or not a message should be logged. For example:

```
WebHost.CreateDefaultBuilder(args)
    .UseStartup<Startup>()
    .ConfigureLogging(logBuilder =>
{
    logBuilder.AddFilter((provider, category, logLevel) =>
    {
        if (provider == "Microsoft.Extensions.Logging.Console.ConsoleLoggerProvider" &&
            category == "TodoApi.Controllers.TodoController")
        {
            return false;
        }
        return true;
    });
})
.Build();
```

Some logging providers let you specify when logs should be written to a storage medium or ignored based on log level and category.

The `AddConsole` and `AddDebug` extension methods provide overloads that let you pass in filtering criteria. The following sample code causes the console provider to ignore logs below `Warning` level, while the Debug provider ignores logs that the framework creates.

```
public void Configure(IApplicationBuilder app,
    IHostingEnvironment env,
    ILoggerFactory loggerFactory)
{
    loggerFactory
        .AddConsole(LogLevel.Warning)
        .AddDebug((category, logLevel) => (category.Contains("TodoApi") && logLevel >= LogLevel.Trace));
```

The `AddEventLog` method has an overload that takes an `EventLogSettings` instance, which may contain a filtering function in its `Filter` property. The `TraceSource` provider doesn't provide any of those overloads, since its logging level and other parameters are based on the `SourceSwitch` and `TraceListener` it uses.

You can set filtering rules for all providers that are registered with an `ILoggerFactory` instance by using the `WithFilter` extension method. The example below limits framework logs (category begins with "Microsoft" or "System") to warnings while letting the app log at debug level.

```

public void Configure(IApplicationBuilder app,
    IHostingEnvironment env,
    ILoggerFactory loggerFactory)
{
    loggerFactory
        .WithFilter(new FilterLoggerSettings
        {
            { "Microsoft", LogLevel.Warning },
            { "System", LogLevel.Warning },
            { "ToDoApi", LogLevel.Debug }
        })
        .AddConsole()
        .AddDebug();
}

```

If you want to use filtering to prevent all logs from being written for a particular category, you can specify `LogLevel.None` as the minimum log level for that category. The integer value of `LogLevel.None` is 6, which is higher than `LogLevel.Critical` (5).

The `WithFilter` extension method is provided by the [Microsoft.Extensions.Logging.Filter](#) NuGet package. The method returns a new `ILoggerFactory` instance that will filter the log messages passed to all logger providers registered with it. It doesn't affect any other `ILoggerFactory` instances, including the original `ILoggerFactory` instance.

## Log scopes

You can group a set of logical operations within a *scope* in order to attach the same data to each log that's created as part of that set. For example, you might want every log created as part of processing a transaction to include the transaction ID.

A scope is an `IDisposable` type that's returned by the `ILogger.BeginScope<TState>` method and lasts until it's disposed. You use a scope by wrapping your logger calls in a `using` block, as shown here:

```

public IActionResult GetById(string id)
{
    TodoItem item;
    using (_logger.BeginScope("Message attached to logs created in the using block"))
    {
        _logger.LogInformation(LoggingEvents.GetItem, "Getting item {ID}", id);
        item = _todoRepository.Find(id);
        if (item == null)
        {
            _logger.LogWarning(LoggingEvents.GetItemNotFound, ".GetById({ID}) NOT FOUND", id);
            return NotFound();
        }
    }
    return new ObjectResult(item);
}

```

The following code enables scopes for the console provider:

*Program.cs:*

```

.ConfigureLogging((hostingContext, logging) =>
{
    logging.AddConfiguration(hostingContext.Configuration.GetSection("Logging"));
    logging.AddConsole(options => options.IncludeScopes = true);
    logging.AddDebug();
})

```

#### NOTE

Configuring the `IncludeScopes` console logger option is required to enable scope-based logging.

`IncludeScopes` can be configured via *appsettings* configuration files. For more information, see the [Settings file configuration](#) section.

*Program.cs*:

```
.ConfigureLogging((hostingContext, logging) =>
{
    logging.AddConfiguration(hostingContext.Configuration.GetSection("Logging"));
    logging.AddConsole(options => options.IncludeScopes = true);
    logging.AddDebug();
})
```

#### NOTE

Configuring the `IncludeScopes` console logger option is required to enable scope-based logging.

*Startup.cs*:

```
public void Configure(IApplicationBuilder app,
    IHostingEnvironment env,
    ILoggerFactory loggerFactory)
{
    loggerFactory
        .AddConsole(includeScopes: true)
        .AddDebug();
```

Each log message includes the scoped information:

```
info: TodoApi.Controllers.TodoController[1002]
    => RequestId:0HKV9C49II9CK RequestPath:/api/todo/0 => TodoApi.Controllers.TodoController.GetById
(TodoApi) => Message attached to logs created in the using block
    Getting item 0
warn: TodoApi.Controllers.TodoController[4000]
    => RequestId:0HKV9C49II9CK RequestPath:/api/todo/0 => TodoApi.Controllers.TodoController.GetById
(TodoApi) => Message attached to logs created in the using block
    GetById(0) NOT FOUND
```

## Built-in logging providers

ASP.NET Core ships the following providers:

- [Console](#)
- [Debug](#)
- [EventSource](#)
- [EventLog](#)
- [TraceSource](#)
- [Azure App Service](#)

### Console provider

The [Microsoft.Extensions.Logging.Console](#) provider package sends log output to the console.

```
logging.AddConsole()
```

```
loggerFactory.AddConsole()
```

[AddConsole overloads](#) let you pass in an a minimum log level, a filter function, and a boolean that indicates whether scopes are supported. Another option is to pass in an `IConfiguration` object, which can specify scopes support and logging levels.

If you are considering the console provider for use in production, be aware that it has a significant impact on performance.

When you create a new project in Visual Studio, the `AddConsole` method looks like this:

```
loggerFactory.AddConsole(Configuration.GetSection("Logging"));
```

This code refers to the `Logging` section of the `appSettings.json` file:

```
{
  "Logging": {
    "Console": {
      "IncludeScopes": false
    },
    "LogLevel": {
      "Default": "Debug",
      "System": "Information",
      "Microsoft": "Information"
    }
  }
}
```

The settings shown limit framework logs to warnings while allowing the app to log at debug level, as explained in the [Log filtering](#) section. For more information, see [Configuration](#).

## Debug provider

The `Microsoft.Extensions.Logging.Debug` provider package writes log output by using the `System.Diagnostics.Debug` class (`Debug.WriteLine` method calls).

On Linux, this provider writes logs to `/var/log/message`.

```
logging.AddDebug()
```

```
loggerFactory.AddDebug()
```

[AddDebug overloads](#) let you pass in a minimum log level or a filter function.

## EventSource provider

For apps that target ASP.NET Core 1.1.0 or higher, the `Microsoft.Extensions.Logging.EventSource` provider package can implement event tracing. On Windows, it uses [ETW](#). The provider is cross-platform, but there are no event collection and display tools yet for Linux or macOS.

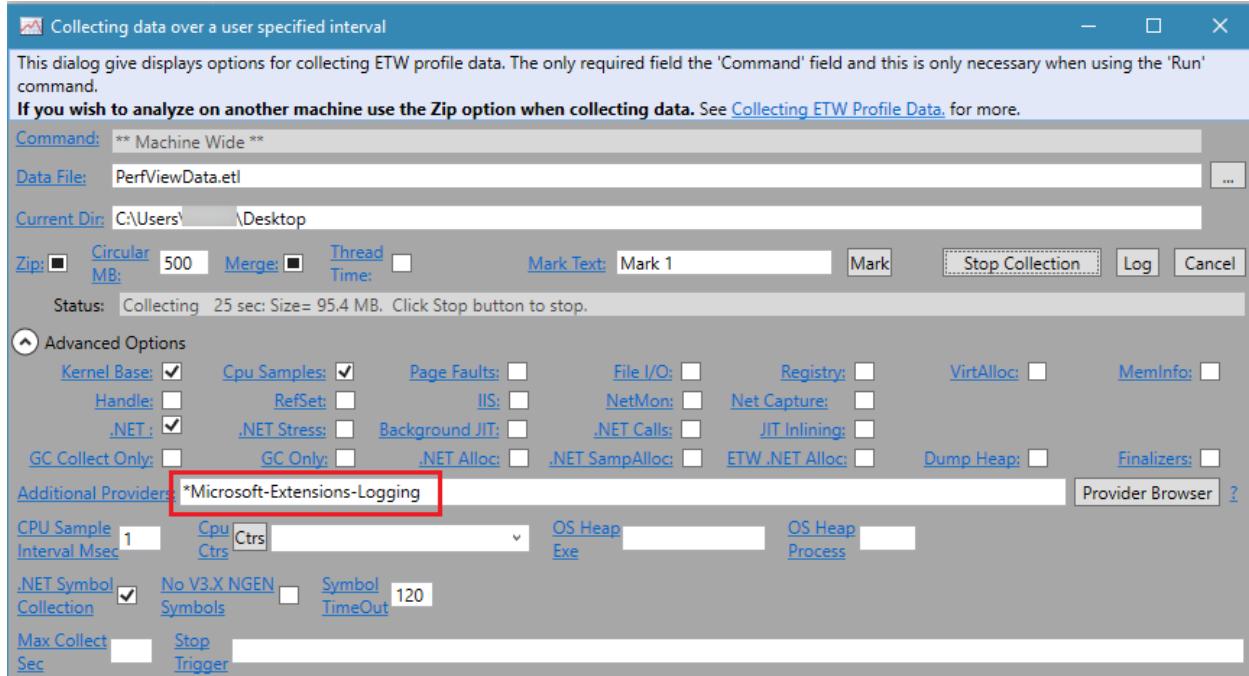

```
logging.AddEventSourceLogger()
```

```
loggerFactory.AddEventSourceLogger()
```

A good way to collect and view logs is to use the [PerfView utility](#). There are other tools for viewing ETW logs, but PerfView provides the best experience for working with the ETW events emitted by ASP.NET.

To configure PerfView for collecting events logged by this provider, add the string

`*Microsoft.Extensions.Logging` to the **Additional Providers** list. (Don't miss the asterisk at the start of the string.)

## Windows EventLog provider

The [Microsoft.Extensions.Logging.EventLog](#) provider package sends log output to the Windows Event Log.

```
logging.AddEventLog()
```

```
loggerFactory.AddEventLog()
```

[AddEventLog](#) overloads let you pass in `EventLogSettings` or a minimum log level.

## TraceSource provider

The [Microsoft.Extensions.Logging.TraceSource](#) provider package uses the [System.Diagnostics.TraceSource](#) libraries and providers.

```
logging.AddTraceSource(sourceSwitchName);
```

```
loggerFactory.AddTraceSource(sourceSwitchName);
```

[AddTraceSource](#) overloads let you pass in a source switch and a trace listener.

To use this provider, an application has to run on the .NET Framework (rather than .NET Core). The provider lets you route messages to a variety of [listeners](#), such as the [TextWriterTraceListener](#) used in the sample application.

The following example configures a `TraceSource` provider that logs `Warning` and higher messages to the

console window.

```
public void Configure(IApplicationBuilder app,
    IHostingEnvironment env,
    ILoggerFactory loggerFactory)
{
    loggerFactory
        .AddDebug();

    // add Trace Source logging
    var testSwitch = new SourceSwitch("sourceSwitch", "Logging Sample");
    testSwitch.Level = SourceLevels.Warning;
    loggerFactory.AddTraceSource(testSwitch,
        new TextWriterTraceListener(writer: Console.Out));
```

## Azure App Service provider

The [Microsoft.Extensions.Logging.AzureAppServices](#) provider package writes logs to text files in an Azure App Service app's file system and to [blob storage](#) in an Azure Storage account. The provider is available only for apps that target ASP.NET Core 1.1 or later.

If targeting .NET Core, don't install the provider package or explicitly call [AddAzureWebAppDiagnostics](#). The provider is automatically available to the app when the app is deployed to Azure App Service.

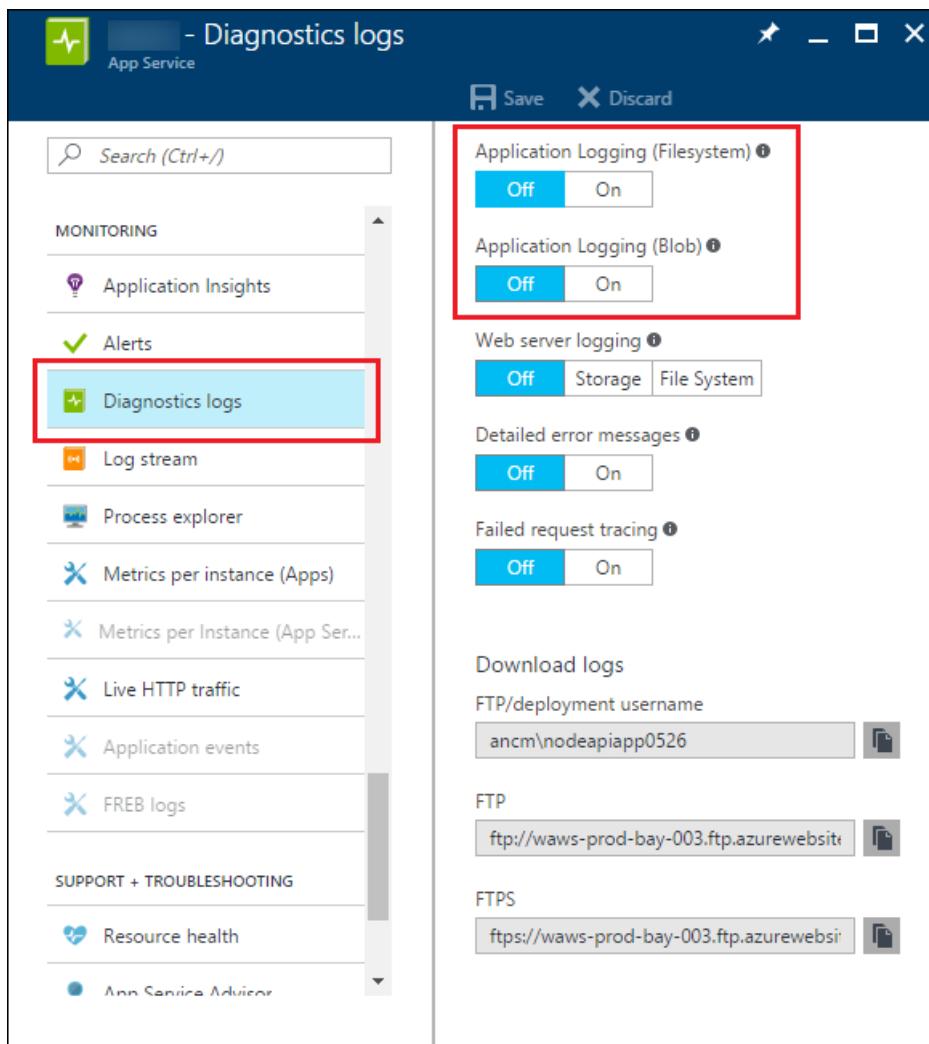

If targeting .NET Framework, add the provider package to the project and invoke [AddAzureWebAppDiagnostics](#):

```
logging.AddAzureWebAppDiagnostics();
```

```
loggerFactory.AddAzureWebAppDiagnostics();
```

An [AddAzureWebAppDiagnostics](#) overload lets you pass in [AzureAppServicesDiagnosticsSettings](#) with which you can override default settings such as the logging output template, blob name, and file size limit. (*Output template* is a message template that's applied to all logs on top of the one that you provide when you call an [ILogger](#) method.)

When you deploy to an App Service app, the app honors the settings in the [Diagnostic Logs](#) section of the **App Service** page of the Azure portal. When these settings are updated, the changes take effect immediately without requiring a restart or redeployment of the app.

The default location for log files is in the `D:\home\LogFiles\Application` folder, and the default file name is `diagnostics-yyyymmdd.txt`. The default file size limit is 10 MB, and the default maximum number of files retained is 2. The default blob name is `{app-name}{timestamp}/yyyy/mm/dd/hh/{guid}-applicationLog.txt`. For more information about default behavior, see [AzureAppServicesDiagnosticsSettings](#).

The provider only works when the project runs in the Azure environment. It has no effect when the project is run locally—it doesn't write to local files or local development storage for blobs.

## Third-party logging providers

Third-party logging frameworks that work with ASP.NET Core:

- [elmah.io \(GitHub repo\)](#)
- [Gelf \(GitHub repo\)](#)
- [JSONLog \(GitHub repo\)](#)
- [Loggr \(GitHub repo\)](#)
- [NLog \(GitHub repo\)](#)
- [Serilog \(GitHub repo\)](#)

Some third-party frameworks can perform [semantic logging](#), also known as structured logging.

Using a third-party framework is similar to using one of the built-in providers:

1. Add a NuGet package to your project.
2. Call an extension method on `ILoggerFactory`.

For more information, see each framework's documentation.

# Azure log streaming

Azure log streaming enables you to view log activity in real time from:

- The application server
- The web server
- Failed request tracing

To configure Azure log streaming:

- Navigate to the **Diagnostics Logs** page from your application's portal page
- Set **Application Logging (Filesystem)** to on.

The screenshot shows the 'Diagnostics logs' configuration page for an Azure App Service. The left sidebar lists various monitoring and troubleshooting tools. The 'Diagnostics logs' section is highlighted with a red box. On the right, the 'Application Logging (Filesystem)' settings are shown, with the 'On' button selected. Below it, the 'Level' is set to 'Warning'. Other sections like 'Application Logging (Blob)', 'Web server logging', and 'Failed request tracing' also have their respective settings visible. At the bottom, there are fields for 'Download logs', 'FTP/deployment username' (set to 'azure-raffle\azure-ftp-deployment-user'), 'FTP' (set to 'ftp://waws-prod-am2-135.ftp.azurewebsites.windows.net'), and 'FTPS' (set to 'ftps://waws-prod-am2-135.ftp.azurewebsites.windows.net').

Navigate to the **Log Streaming** page to view application messages. They're logged by application through the `ILogger` interface.

The screenshot shows the Azure Log stream interface for an App Service. The left sidebar contains a navigation menu with the following items:

- Search (Ctrl+ /)
- Performance test
- Resource explorer
- Testing in production
- Extensions
- MOBILE

  - Easy tables
  - Easy APIs
  - Data connections

- API

  - API definition
  - CORS

- MONITORING

  - Application Insights
  - Alerts
  - Diagnostics logs
  - Log stream** (highlighted with a red box)
  - Process explorer

- SUPPORT + TROUBLESHOOTING

  - Resource health
  - App Service Advisor

The main area displays the log stream with the following content:

```
Connecting...
2017-11-16T18:39:47 Welcome, you are now connected to log-streaming service.

## Azure Application Insights trace logging

The [Application Insights SDK](#) is capable of collecting trace telemetry from logs generated via the ASP.NET Core logging infrastructure. For more information, see [Microsoft/ApplicationInsights-aspnetcore Wiki: Logging](#).

## Additional resources

[High-performance logging with LoggerMessage](#)

# High-performance logging with LoggerMessage in ASP.NET Core

6/21/2018 • 7 minutes to read • [Edit Online](#)

By [Luke Latham](#)

`LoggerMessage` features create cacheable delegates that require fewer object allocations and reduced computational overhead compared to `logger extension methods`, such as `LogInformation`, `LogDebug`, and `.LogError`. For high-performance logging scenarios, use the `LoggerMessage` pattern.

`LoggerMessage` provides the following performance advantages over `Logger extension methods`:

- `Logger extension methods` require "boxing" (converting) value types, such as `int`, into `object`. The `LoggerMessage` pattern avoids boxing by using static `Action` fields and extension methods with strongly-typed parameters.
- `Logger extension methods` must parse the message template (named format string) every time a log message is written. `LoggerMessage` only requires parsing a template once when the message is defined.

[View or download sample code \(how to download\)](#)

The sample app demonstrates `LoggerMessage` features with a basic quote tracking system. The app adds and deletes quotes using an in-memory database. As these operations occur, log messages are generated using the `LoggerMessage` pattern.

## LoggerMessage.Define

`Define(LogLevel, EventId, String)` creates an `Action` delegate for logging a message. `Define` overloads permit passing up to six type parameters to a named format string (template).

The string provided to the `Define` method is a template and not an interpolated string. Placeholders are filled in the order that the types are specified. Placeholder names in the template should be descriptive and consistent across templates. They serve as property names within structured log data. We recommend [Pascal casing](#) for placeholder names. For example, `{Count}`, `{FirstName}`.

Each log message is an `Action` held in a static field created by `LoggerMessage.Define`. For example, the sample app creates a field to describe a log message for a GET request for the Index page (*Internal/LoggerExtensions.cs*):

```
private static readonly Action<ILogger, Exception> _indexPageRequested;
```

For the `Action`, specify:

- The log level.
- A unique event identifier (`EventId`) with the name of the static extension method.
- The message template (named format string).

A request for the Index page of the sample app sets the:

- Log level to `Information`.
- Event id to `1` with the name of the `IndexPageRequested` method.
- Message template (named format string) to a string.

```
_indexPageRequested = LoggerMessage.Define(
    LogLevel.Information,
    new EventId(1, nameof(IndexPageRequested)),
    "GET request for Index page");
```

Structured logging stores may use the event name when it's supplied with the event id to enrich logging. For example, [Serilog](#) uses the event name.

The `Action` is invoked through a strongly-typed extension method. The `IndexPageRequested` method logs a message for an Index page GET request in the sample app:

```
public static void IndexPageRequested(this ILogger logger)
{
    _indexPageRequested(logger, null);
}
```

`IndexPageRequested` is called on the logger in the `OnGetAsync` method in *Pages/Index.cshtml.cs*:

```
public async Task OnGetAsync()
{
    _logger.IndexPageRequested();

    Quotes = await _db.Quotes.AsNoTracking().ToListAsync();
}
```

Inspect the app's console output:

```
info: LoggerMessageSample.Pages.IndexModel[1]
      => RequestId:0HL90M6E7PHK4:00000001 RequestPath:/ => /Index
        GET request for Index page
```

To pass parameters to a log message, define up to six types when creating the static field. The sample app logs a string when adding a quote by defining a `string` type for the `Action` field:

```
private static readonly Action<ILogger, string, Exception> _quoteAdded;
```

The delegate's log message template receives its placeholder values from the types provided. The sample app defines a delegate for adding a quote where the quote parameter is a `string`:

```
_quoteAdded = LoggerMessage.Define<string>(
    LogLevel.Information,
    new EventId(2, nameof(QuoteAdded)),
    "Quote added (Quote = '{Quote}')");
```

The static extension method for adding a quote, `QuoteAdded`, receives the quote argument value and passes it to the `Action` delegate:

```
public static void QuoteAdded(this ILogger logger, string quote)
{
    _quoteAdded(logger, quote, null);
}
```

In the Index page's page model (*Pages/Index.cshtml.cs*), `quoteAdded` is called to log the message:

```

public async Task<IActionResult> OnPostAddQuoteAsync()
{
    _db.Quotes.Add(Quote);
    await _db.SaveChangesAsync();

    _logger.QuoteAdded(Quote.Text);

    return RedirectToAction();
}

```

Inspect the app's console output:

```

info: LoggerMessageSample.Pages.IndexModel[2]
      => RequestId:0HL90M6E7PHK5:0000000A RequestPath:/ => /Index
      Quote added (Quote = 'You can avoid reality, but you cannot avoid the consequences of avoiding reality.
      - Ayn Rand')

```

The sample app implements a `try – catch` pattern for quote deletion. An informational message is logged for a successful delete operation. An error message is logged for a delete operation when an exception is thrown. The log message for the unsuccessful delete operation includes the exception stack trace (*Internal/LoggerExtensions.cs*):

```

private static readonly Action<ILogger, string, int, Exception> _quoteDeleted;
private static readonly Action<ILogger, int, Exception> _quoteDeleteFailed;

```

```

_quoteDeleted = LoggerMessage.Define<string, int>(
    LogLevel.Information,
    new EventId(4, nameof(QuoteDeleted)),
    "Quote deleted (Quote = '{Quote}' Id = {Id})");

_quoteDeleteFailed = LoggerMessage.Define<int>(
    LogLevel.Error,
    new EventId(5, nameof(QuoteDeleteFailed)),
    "Quote delete failed (Id = {Id})");

```

Note how the exception is passed to the delegate in `QuoteDeleteFailed`:

```

public static void QuoteDeleted(this ILogger logger, string quote, int id)
{
    _quoteDeleted(logger, quote, id, null);
}

public static void QuoteDeleteFailed(this ILogger logger, int id, Exception ex)
{
    _quoteDeleteFailed(logger, id, ex);
}

```

In the page model for the Index page, a successful quote deletion calls the `QuoteDeleted` method on the logger. When a quote isn't found for deletion, an `ArgumentNullException` is thrown. The exception is trapped by the `try – catch` statement and logged by calling the `QuoteDeleteFailed` method on the logger in the `catch` block (*Pages/Index.cshtml.cs*):

```

public async Task<IActionResult> OnPostDeleteQuoteAsync(int id)
{
    var quote = await _db.Quotes.FindAsync(id);

    // DO NOT use this approach in production code!
    // You should check quote to see if it's null before removing
    // it and saving changes to the database. A try-catch is used
    // here for demonstration purposes of LoggerMessage features.
    try
    {
        _db.Quotes.Remove(quote);
        await _db.SaveChangesAsync();

        _logger.QuoteDeleted(quote.Text, id);
    }
    catch (ArgumentNullException ex)
    {
        _logger.QuoteDeleteFailed(id, ex);
    }

    return RedirectToAction();
}

```

When a quote is successfully deleted, inspect the app's console output:

```

info: LoggerMessageSample.Pages.IndexModel[4]
=> RequestId:0HL90M6E7PHK5:00000016 RequestPath:/ => /Index
    Quote deleted (Quote = 'You can avoid reality, but you cannot avoid the consequences of avoiding
    reality. - Ayn Rand' Id = 1)

```

When quote deletion fails, inspect the app's console output. Note that the exception is included in the log message:

```

fail: LoggerMessageSample.Pages.IndexModel[5]
=> RequestId:0HL90M6E7PHK5:00000010 RequestPath:/ => /Index
    Quote delete failed (Id = 999)
System.ArgumentNullException: Value cannot be null.

```

## LoggerMessage.DefineScope

[DefineScope\(String\)](#) creates a `Func` delegate for defining a [log scope](#). `DefineScope` overloads permit passing up to three type parameters to a named format string (template).

As is the case with the `Define` method, the string provided to the `DefineScope` method is a template and not an interpolated string. Placeholders are filled in the order that the types are specified. Placeholder names in the template should be descriptive and consistent across templates. They serve as property names within structured log data. We recommend [Pascal casing](#) for placeholder names. For example, `{Count}`, `{FirstName}`.

Define a [log scope](#) to apply to a series of log messages using the [DefineScope\(String\)](#) method.

The sample app has a **Clear All** button for deleting all of the quotes in the database. The quotes are deleted by removing them one at a time. Each time a quote is deleted, the `QuoteDeleted` method is called on the logger. A log scope is added to these log messages.

Enable `IncludeScopes` in the console logger section of `appsettings.json`:

```
{  
  "Logging": {  
    "Console": {  
      "IncludeScopes": true  
    },  
    "LogLevel": {  
      "Default": "Warning"  
    }  
  },  
  "AllowedHosts": "*"  
}
```

To create a log scope, add a field to hold a `Func` delegate for the scope. The sample app creates a field called `_allQuotesDeletedScope` (`Internal/LoggerExtensions.cs`):

```
private static Func<ILogger, int, IDisposable> _allQuotesDeletedScope;
```

Use `DefineScope` to create the delegate. Up to three types can be specified for use as template arguments when the delegate is invoked. The sample app uses a message template that includes the number of deleted quotes (an `int` type):

```
_allQuotesDeletedScope = LoggerMessage.DefineScope<int>("All quotes deleted (Count = {Count})");
```

Provide a static extension method for the log message. Include any type parameters for named properties that appear in the message template. The sample app takes in a `count` of quotes to delete and returns

```
_allQuotesDeletedScope :
```

```
public static IDisposable AllQuotesDeletedScope(this ILogger logger, int count)  
{  
    return _allQuotesDeletedScope(logger, count);  
}
```

The scope wraps the logging extension calls in a `using` block:

```
public async Task<IActionResult> OnPostDeleteAllQuotesAsync()  
{  
    var quoteCount = await _db.Quote.CountAsync();  
  
    using (_logger.AllQuotesDeletedScope(quoteCount))  
    {  
        foreach (Quote quote in _db.Quote)  
        {  
            _db.Quote.Remove(quote);  
  
            _logger.QuoteDeleted(quote.Text, quote.Id);  
        }  
        await _db.SaveChangesAsync();  
    }  
  
    return RedirectToPage();  
}
```

Inspect the log messages in the app's console output. The following result shows three quotes deleted with the log scope message included:

```
info: LoggerMessageSample.Pages.IndexModel[4]
=> RequestId:0HL90M6E7PHK5:0000002E RequestPath:/ => /Index => All quotes deleted (Count = 3)
  Quote deleted (Quote = 'Quote 1' Id = 2)
info: LoggerMessageSample.Pages.IndexModel[4]
=> RequestId:0HL90M6E7PHK5:0000002E RequestPath:/ => /Index => All quotes deleted (Count = 3)
  Quote deleted (Quote = 'Quote 2' Id = 3)
info: LoggerMessageSample.Pages.IndexModel[4]
=> RequestId:0HL90M6E7PHK5:0000002E RequestPath:/ => /Index => All quotes deleted (Count = 3)
  Quote deleted (Quote = 'Quote 3' Id = 4)
```

# Handle errors in ASP.NET Core

7/10/2018 • 6 minutes to read • [Edit Online](#)

By [Steve Smith](#) and [Tom Dykstra](#)

This article covers common approaches to handling errors in ASP.NET Core apps.

[View or download sample code \(how to download\)](#)

## The developer exception page

To configure an app to display a page that shows detailed information about exceptions, use the *developer exception page*. The page made available by the [Microsoft.AspNetCore.Diagnostics](#) package, which is available in the [Microsoft.AspNetCore.App metapackage](#). Add a line to the `Startup.Configure` method:

To configure an app to display a page that shows detailed information about exceptions, use the *developer exception page*. The page is made available by the [Microsoft.AspNetCore.Diagnostics](#) package, which is available in the [Microsoft.AspNetCore.All metapackage](#). Add a line to the `Startup.Configure` method:

To configure an app to display a page that shows detailed information about exceptions, use the *developer exception page*. The page is made available by adding a package reference for the [Microsoft.AspNetCore.Diagnostics](#) package in the project file. Add a line to the `Startup.Configure` method:

```
public void Configure(IApplicationBuilder app, IHostingEnvironment env)
{
    env.EnvironmentName = EnvironmentName.Production;

    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
    }
    else
    {
        app.UseExceptionHandler("/error");
    }
}
```

Place the call to [UseDeveloperExceptionPage](#) in front of any middleware where you want to catch exceptions, such as `app.UseMvc`.

### WARNING

Enable the developer exception page **only when the app is running in the Development environment**. You don't want to share detailed exception information publicly when the app runs in production. [Learn more about configuring environments](#).

To see the developer exception page, run the sample app with the environment set to `Development`, and add `?throw=true` to the base URL of the app. The page includes several tabs with information about the exception and the request. The first tab includes a stack trace:

An unhandled exception occurred while processing the request.

Exception: Exception triggered!

```
ErrorHandlingSample.Startup+<>c+<<Configure>b__1_4>d.MoveNext() in Startup.cs, line 67
```

Stack    Query    Cookies    Headers

Exception: Exception triggered!

```
ErrorHandlingSample.Startup+<>c+<<Configure>b__1_4>d.MoveNext() in Startup.cs
+   67.           var builder = new StringBuilder();
System.Runtime.ExceptionServices.ExceptionDispatchInfo.Throw()
Syste...[redacted]m.Runtime.CompilerServices.TaskAwaiter.HandleNonSuccessAndDebuggerNotification(Task task)
```

```
Syste...[redacted]m.Runtime.CompilerServices.TaskAwaiter.HandleNonSuccessAndDebuggerNotification(Task task)
Microsoft.AspNetCore.Diagnostics.DeveloperExceptionPageMiddleware+<Invoke>d__7.MoveNext()
```

Show raw exception details

The next tab shows the query string parameters, if any:

An unhandled exception occurred while processing the request.

Exception: Exception triggered!

```
ErrorHandlingSample.Startup+<>c+<<Configure>b__1_4>d.MoveNext() in Startup.cs, line 67
```

Stack    **Query**    Cookies    Headers

Variable	Value
throw	true

If the request has cookies, they appear on the **Cookies** tab. Headers are seen in the last tab:

An unhandled exception occurred while processing the request.

Exception: Exception triggered!

ErrorHandlingSample.Startup+<>c+<<Configure>b\_1\_4>d.MoveNext() in Startup.cs, line 67

Stack	Query	Cookies	Headers
Variable	Value

## Configuring a custom exception handling page

Configure an exception handler page to use when the app isn't running in the `Development` environment:

```
public void Configure(IApplicationBuilder app, IHostingEnvironment env)
{
    env.EnvironmentName = EnvironmentName.Production;

    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
    }
    else
    {
        app.UseExceptionHandler("/error");
    }
}
```

In a Razor Pages app, the `dotnet new` Razor Pages template provides an Error page and `ErrorModel` page model class in the *Pages* folder.

In an MVC app, don't decorate the error handler action method with HTTP method attributes, such as `HttpGet`. Explicit verbs prevent some requests from reaching the method. Allow anonymous access to the method so that unauthenticated users are able to receive the error view.

For example, the following error handler method is provided by the `dotnet new` MVC template and appears in the Home controller:

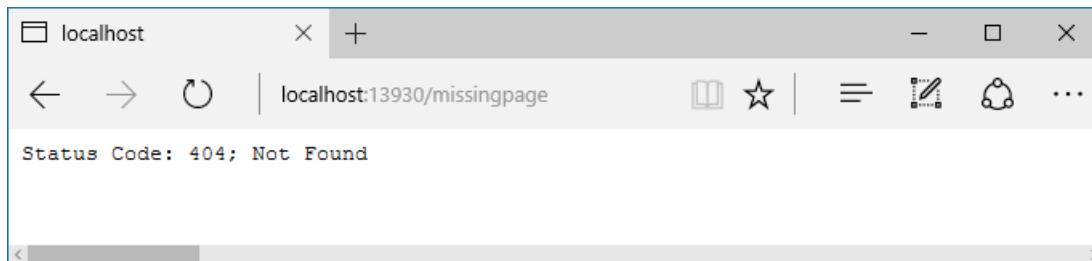

```
[AllowAnonymous]
public IActionResult Error()
{
    return View(new ErrorViewModel
    { RequestId = Activity.Current?.Id ?? HttpContext.TraceIdentifier });
}
```

## Configuring status code pages

By default, an app doesn't provide a rich status code page for HTTP status codes, such as *404 Not Found*. To provide status code pages, configure the Status Code Pages Middleware by adding a line to the `Startup.Configure` method:

```
app.UseStatusCodePages();
```

By default, Status Code Pages Middleware adds text-only handlers for common status codes, such as 404:

The middleware supports several extension methods. One method takes a lambda expression:

```
app.UseStatusCodePages(async context =>
{
    context.HttpContext.Response.ContentType = "text/plain";

    await context.HttpContext.Response.WriteAsync(
        "Status code page, status code: " +
        context.HttpContext.Response.StatusCode);
});
```

Another method takes a content type and format string:

```
app.UseStatusCodePages("text/plain", "Status code page, status code: {0}");
```

There's also redirect and re-execute extension methods. The redirect method sends a *302 Found* status code to the client:

```
app.UseStatusCodePagesWithRedirects("/error/{0}");
```

The re-execute method returns the original status code to the client but also executes the handler for the redirect URL:

```
app.UseStatusCodePagesWithReExecute("/error/{0}");
```

Status code pages can be disabled for specific requests in a Razor Pages handler method or in an MVC controller. To disable status code pages, attempt to retrieve the `IStatusCodePagesFeature` from the request's `HttpContext.Features` collection and disable the feature if it's available:

```

var statusCodePagesFeature = HttpContext.Features.Get<IStatusCodePagesFeature>();

if (statusCodePagesFeature != null)
{
    statusCodePagesFeature.Enabled = false;
}

```

If using a `UseStatusCodePages*` overload that points to an endpoint within the app, create an MVC view or Razor Page for the endpoint. For example, the `dotnet new` template for a Razor Pages app produces the following page and page model class:

*Error.cshtml:*

```

@page
@model ErrorModel
 @{
     ViewData["Title"] = "Error";
 }

<h1 class="text-danger">Error.</h1>
<h2 class="text-danger">An error occurred while processing your request.</h2>

@if (Model.ShowRequestId)
{
    <p>
        <strong>Request ID:</strong> <code>@Model.RequestId</code>
    </p>
}

<h3>Development Mode</h3>
<p>
    Swapping to <strong>Development</strong> environment will display more detailed
    information about the error that occurred.
</p>
<p>
    <strong>Development environment should not be enabled in deployed applications
    </strong>, as it can result in sensitive information from exceptions being
    displayed to end users. For local debugging, development environment can be
    enabled by setting the <strong>ASPNETCORE_ENVIRONMENT</strong> environment
    variable to <strong>Development</strong>, and restarting the application.
</p>

```

*Error.cshtml.cs:*

```

public class ErrorModel : PageModel
{
    public string RequestId { get; set; }

    public bool ShowRequestId => !string.IsNullOrEmpty(RequestId);

    [ResponseCache(Duration = 0, Location = ResponseCacheLocation.None,
        NoStore = true)]
    public void OnGet()
    {
        RequestId = Activity.Current?.Id ?? HttpContext.TraceIdentifier;
    }
}

```

## Exception-handling code

Code in exception handling pages can throw exceptions. It's often a good idea for production error pages to

consist of purely static content.

Also, be aware that once the headers for a response have been sent, you can't change the response's status code, nor can any exception pages or handlers run. The response must be completed or the connection aborted.

## Server exception handling

In addition to the exception handling logic in your app, the [server](#) hosting your app performs some exception handling. If the server catches an exception before the headers are sent, the server sends a *500 Internal Server Error* response with no body. If the server catches an exception after the headers have been sent, the server closes the connection. Requests that aren't handled by your app are handled by the server. Any exception that occurs is handled by the server's exception handling. Any configured custom error pages or exception handling middleware or filters don't affect this behavior.

## Startup exception handling

Only the hosting layer can handle exceptions that take place during app startup. Using the [Web Host](#), you can [configure how the host behaves in response to errors during startup](#) with the `captureStartupErrors` and `detailedErrors` keys.

Hosting can only show an error page for a captured startup error if the error occurs after host address/port binding. If any binding fails for any reason, the hosting layer logs a critical exception, the dotnet process crashes, and no error page is displayed when the app is running on the [Kestrel](#) server.

When running on [IIS](#) or [IIS Express](#), a *502.5 Process Failure* is returned by the [ASP.NET Core Module](#) if the process can't be started. For information on troubleshooting startup issues when hosting with IIS, see [Troubleshoot ASP.NET Core on IIS](#). For information on troubleshooting startup issues with Azure App Service, see [Troubleshoot ASP.NET Core on Azure App Service](#).

## ASP.NET MVC error handling

[MVC](#) apps have some additional options for handling errors, such as configuring exception filters and performing model validation.

### Exception filters

Exception filters can be configured globally or on a per-controller or per-action basis in an MVC app. These filters handle any unhandled exception that occurs during the execution of a controller action or another filter. These filters aren't called otherwise. To learn more, see [Filters](#).

#### TIP

Exception filters are good for trapping exceptions that occur within MVC actions, but they're not as flexible as error handling middleware. Generally prefer the use of middleware, and use filters only where you need to perform error handling *differently* based on which MVC action is chosen.

### Handling model state errors

[Model validation](#) occurs prior to invoking each controller action, and it's the action method's responsibility to inspect `ModelState.IsValid` and react appropriately.

Some apps choose to follow a standard convention for dealing with model validation errors, in which case a [filter](#) may be an appropriate place to implement such a policy. You should test how your actions behave with invalid model states. Learn more in [Test controller logic](#).

# File Providers in ASP.NET Core

6/21/2018 • 6 minutes to read • [Edit Online](#)

By [Steve Smith](#)

ASP.NET Core abstracts file system access through the use of File Providers.

[View or download sample code \(how to download\)](#)

## File Provider abstractions

File Providers are an abstraction over file systems. The main interface is `IFileProvider`. `IFileProvider` exposes methods to get file information (`IFileInfo`), directory information (`IDirectoryContents`), and to set up change notifications (using an `IChangeToken`).

`IFileInfo` provides methods and properties about individual files or directories. It has two boolean properties, `Exists` and `IsDirectory`, as well as properties describing the file's `Name`, `Length` (in bytes), and `LastModified` date. You can read from the file using its `CreateReadStream` method.

## File Provider implementations

Three implementations of `IFileProvider` are available: Physical, Embedded, and Composite. The physical provider is used to access the actual system's files. The embedded provider is used to access files embedded in assemblies. The composite provider is used to provide combined access to files and directories from one or more other providers.

### PhysicalFileProvider

The `PhysicalFileProvider` provides access to the physical file system. It wraps the `System.IO.File` type (for the physical provider), scoping all paths to a directory and its children. This scoping limits access to a certain directory and its children, preventing access to the file system outside of this boundary. When instantiating this provider, you must provide it with a directory path, which serves as the base path for all requests made to this provider (and which restricts access outside of this path). In an ASP.NET Core app, you can instantiate a `PhysicalFileProvider` provider directly, or you can request an `IFileProvider` in a Controller or service's constructor through [dependency injection](#). The latter approach will typically yield a more flexible and testable solution.

The sample below shows how to create a `PhysicalFileProvider`.

```
IFileProvider provider = new PhysicalFileProvider(applicationRoot);
IDirectoryContents contents = provider.GetDirectoryContents(""); // the applicationRoot contents
IFileInfo fileInfo = provider.GetFileInfo("wwwroot/js/site.js"); // a file under applicationRoot
```

You can iterate through its directory contents or get a specific file's information by providing a subpath.

To request a provider from a controller, specify it in the controller's constructor and assign it to a local field. Use the local instance from your action methods:

```

public class HomeController : Controller
{
    private readonly IFileProvider _fileProvider;

    public HomeController(IFileProvider fileProvider)
    {
        _fileProvider = fileProvider;
    }

    public IActionResult Index()
    {
        var contents = _fileProvider.GetDirectoryContents("");
        return View(contents);
    }
}

```

Then, create the provider in the app's `Startup` class:

```

using System.Linq;
using System.Reflection;
using Microsoft.AspNetCore.Builder;
using Microsoft.AspNetCore.Hosting;
using Microsoft.Extensions.Configuration;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.FileProviders;
using Microsoft.Extensions.Logging;

namespace FileProviderSample
{
    public class Startup
    {
        private IHostingEnvironment _hostingEnvironment;
        public Startup(IHostingEnvironment env)
        {
            var builder = new ConfigurationBuilder()
                .SetBasePath(env.ContentRootPath)
                .AddJsonFile("appsettings.json", optional: true, reloadOnChange: true)
                .AddJsonFile($"appsettings.{env.EnvironmentName}.json", optional: true)
                .AddEnvironmentVariables();
            Configuration = builder.Build();

            _hostingEnvironment = env;
        }

        public IConfigurationRoot Configuration { get; }

        // This method gets called by the runtime. Use this method to add services to the container.
        public void ConfigureServices(IServiceCollection services)
        {
            // Add framework services.
            services.AddMvc();

            var physicalProvider = _hostingEnvironment.ContentRootFileProvider;
            var embeddedProvider = new EmbeddedFileProvider(Assembly.GetEntryAssembly());
            var compositeProvider = new CompositeFileProvider(physicalProvider, embeddedProvider);

            // choose one provider to use for the app and register it
            //services.AddSingleton<IFileProvider>(physicalProvider);
            //services.AddSingleton<IFileProvider>(embeddedProvider);
            services.AddSingleton<IFileProvider>(compositeProvider);
        }
}

```

In the `/Index.cshtml` view, iterate through the `IDirectoryContents` provided:

```

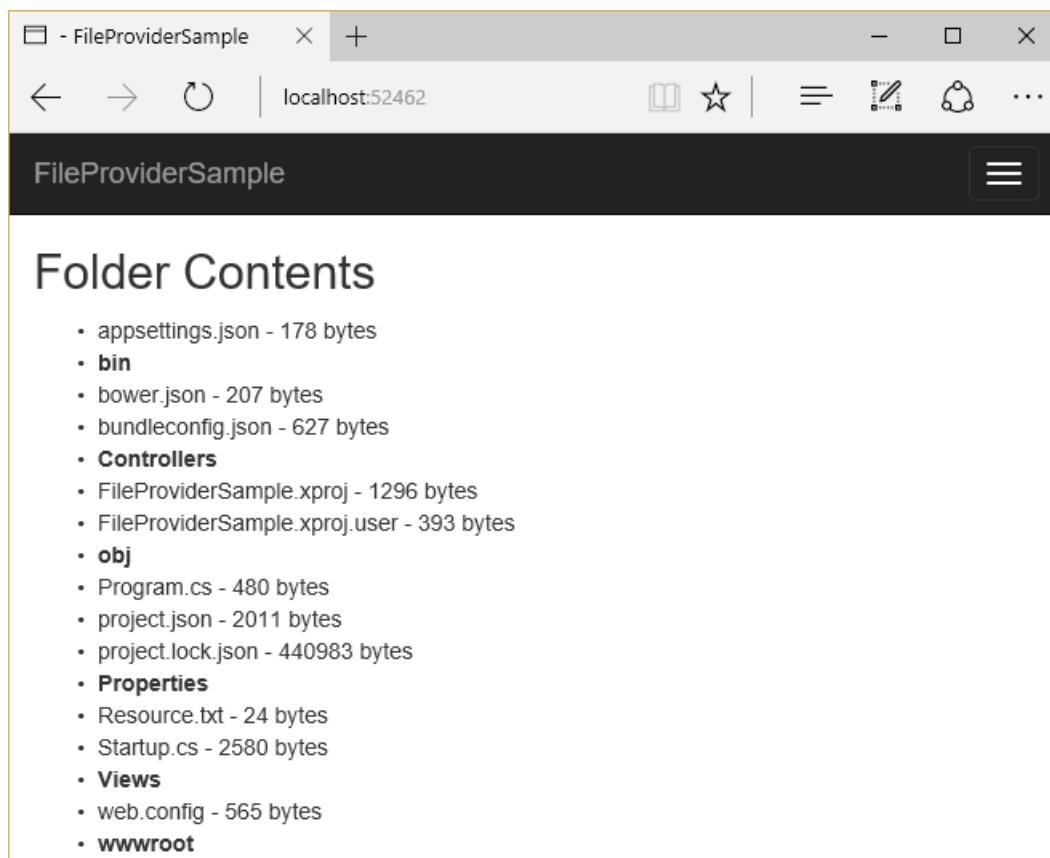

@using Microsoft.Extensions.FileProviders
@model IDirectoryContents

<h2>Folder Contents</h2>

<ul>
    @foreach (IFileInfo item in Model)
    {
        if (item.IsDirectory)
        {
            <li><strong>@item.Name</strong></li>
        }
        else
        {
            <li>@item.Name - @item.Length bytes</li>
        }
    }
</ul>

```

The result:

## EmbeddedFileProvider

The `EmbeddedFileProvider` is used to access files embedded in assemblies. In .NET Core, you embed files in an assembly with the `<EmbeddedResource>` element in the `.csproj` file:

```

<ItemGroup>
    <EmbeddedResource Include="Resource.txt;**\*.js"
        Exclude="bin\**;obj\**;**\*.xproj;packages\**;@(EmbeddedResource)" />
    <Content Update="wwwroot\**\*;Views\**\*;Areas\**\Views;appsettings.json;web.config">
        <CopyToPublishDirectory>PreserveNewest</CopyToPublishDirectory>
    </Content>
</ItemGroup>

```

You can use [globbing patterns](#) when specifying files to embed in the assembly. These patterns can be used to

match one or more files.

#### NOTE

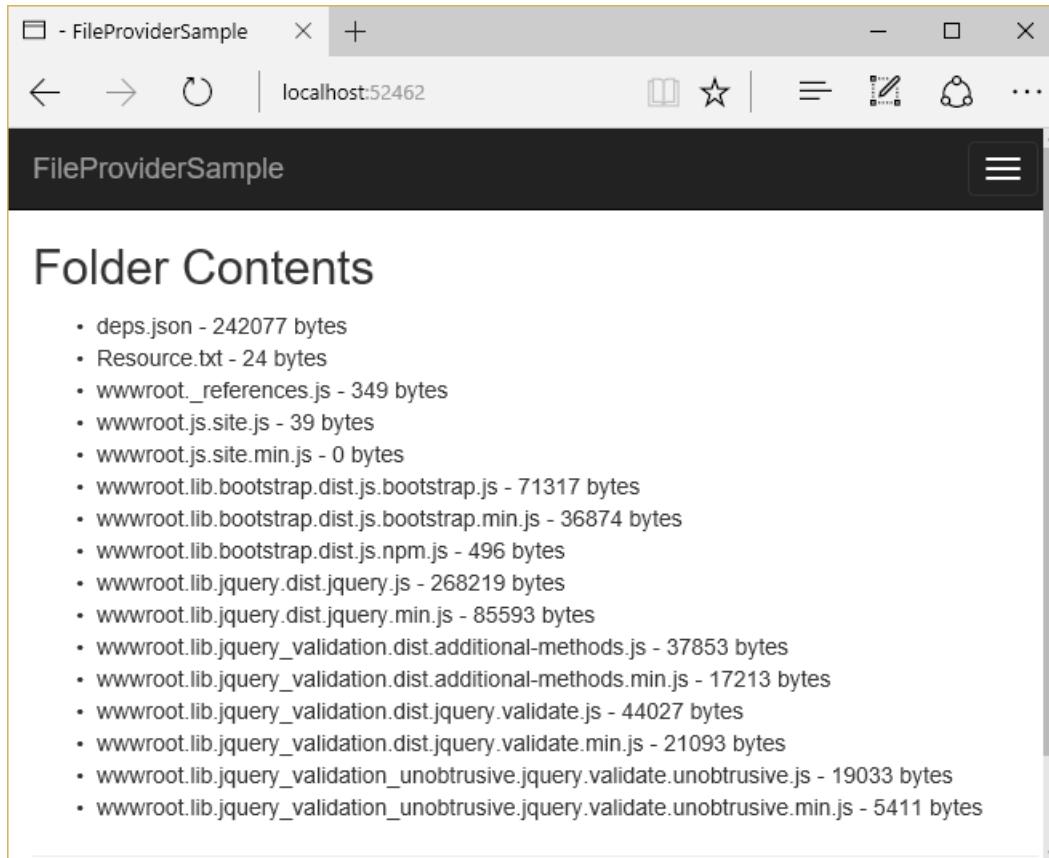

It's unlikely you would ever want to actually embed every .js file in your project in its assembly; the above sample is for demo purposes only.

When creating an `EmbeddedFileProvider`, pass the assembly it will read to its constructor.

```
var embeddedProvider = new EmbeddedFileProvider(Assembly.GetEntryAssembly());
```

The snippet above demonstrates how to create an `EmbeddedFileProvider` with access to the currently executing assembly.

Updating the sample app to use an `EmbeddedFileProvider` results in the following output:

#### NOTE

Embedded resources don't expose directories. Rather, the path to the resource (via its namespace) is embedded in its filename using `.` separators.

#### TIP

The `EmbeddedFileProvider` constructor accepts an optional `baseNamespace` parameter. Specifying this will scope calls to `GetDirectoryContents` to those resources under the provided namespace.

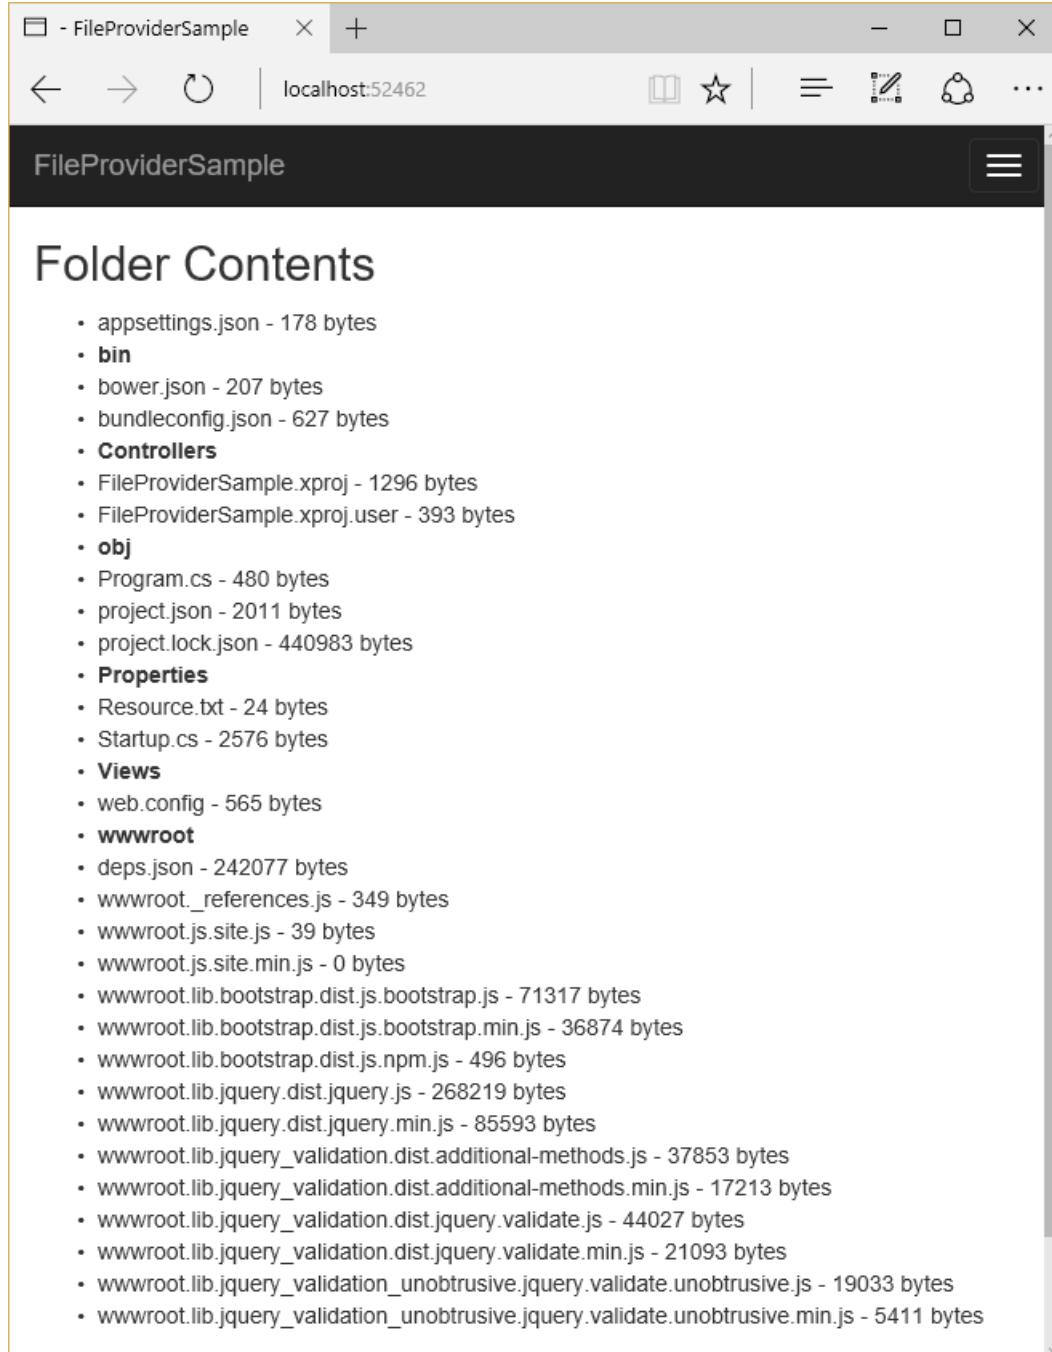

## CompositeFileProvider

The `CompositeFileProvider` combines `IFileProvider` instances, exposing a single interface for working with files from multiple providers. When creating the `CompositeFileProvider`, you pass one or more `IFileProvider`

instances to its constructor:

```
var physicalProvider = _hostingEnvironment.ContentRootFileProvider;
var embeddedProvider = new EmbeddedFileProvider(Assembly.GetEntryAssembly());
var compositeProvider = new CompositeFileProvider(physicalProvider, embeddedProvider);
```

Updating the sample app to use a `CompositeFileProvider` that includes both the physical and embedded providers configured previously, results in the following output:

## Watching for changes

The `IFileProvider` `Watch` method provides a way to watch one or more files or directories for changes. This method accepts a path string, which can use [globbing patterns](#) to specify multiple files, and returns an `IChangeToken`. This token exposes a `HasChanged` property that can be inspected, and a `RegisterChangeCallback` method that's called when changes are detected to the specified path string. Note that each change token only calls its associated callback in response to a single change. To enable constant monitoring, you can use a `TaskCompletionSource` as shown below, or re-create `IChangeToken` instances in response to changes.

In this article's sample, a console application is configured to display a message whenever a text file is modified:

```
private static PhysicalFileProvider _fileProvider =
    new PhysicalFileProvider(Directory.GetCurrentDirectory());

public static void Main(string[] args)
{
    Console.WriteLine("Monitoring quotes.txt for changes (Ctrl-c to quit)...");

    while (true)
    {
        MainAsync().GetAwaiter().GetResult();
    }
}

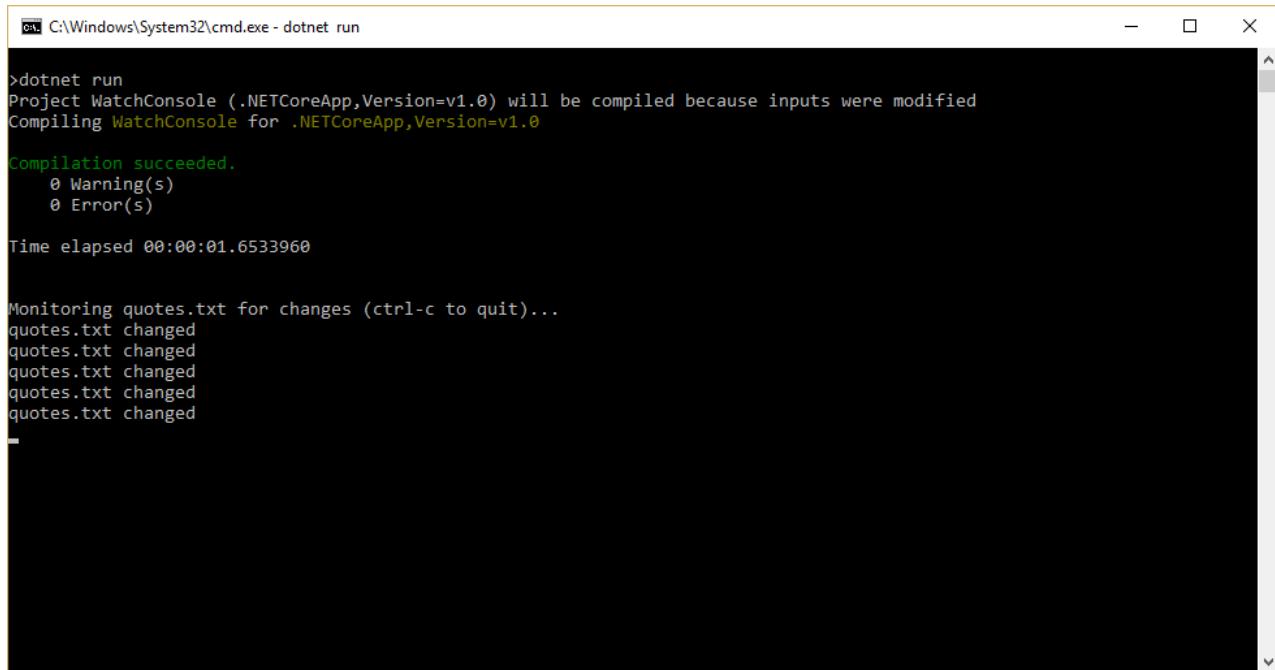

private static async Task MainAsync()
{
    IChangeToken token = _fileProvider.Watch("quotes.txt");
    var tcs = new TaskCompletionSource<object>();

    token.RegisterChangeCallback(state =>
        ((TaskCompletionSource<object>)state).TrySetResult(null), tcs);

    await tcs.Task.ConfigureAwait(false);

    Console.WriteLine("quotes.txt changed");
}
```

The result, after saving the file several times:

```
C:\Windows\System32\cmd.exe - dotnet run

>dotnet run
Project WatchConsole (.NETCoreApp,Version=v1.0) will be compiled because inputs were modified
Compiling WatchConsole for .NETCoreApp,Version=v1.0

Compilation succeeded.
  0 Warning(s)
  0 Error(s)

Time elapsed 00:00:01.6533960

Monitoring quotes.txt for changes (ctrl-c to quit)...
quotes.txt changed
quotes.txt changed
quotes.txt changed
quotes.txt changed
quotes.txt changed
```

#### NOTE

Some file systems, such as Docker containers and network shares, may not reliably send change notifications. Set the `DOTNET_USE_POLLINGFILEWATCHER` environment variable to `1` or `true` to poll the file system for changes every 4 seconds.

## Globbing patterns

File system paths use wildcard patterns called *globbing patterns*. These simple patterns can be used to specify groups of files. The two wildcard characters are `*` and `**`.

\*

Matches anything at the current folder level, or any filename, or any file extension. Matches are terminated by `/` and `.` characters in the file path.

\*\*

Matches anything across multiple directory levels. Can be used to recursively match many files within a directory hierarchy.

## Globbing pattern examples

`directory/file.txt`

Matches a specific file in a specific directory.

`directory/*.txt`

Matches all files with `.txt` extension in a specific directory.

`directory/*bower.json`

Matches all `bower.json` files in directories exactly one level below the `directory` directory.

`directory/**/*.txt`

Matches all files with `.txt` extension found anywhere under the `directory` directory.

## File Provider usage in ASP.NET Core

Several parts of ASP.NET Core utilize file providers. `IHostingEnvironment` exposes the app's content root and web root as `IFileProvider` types. The static files middleware uses file providers to locate static files. Razor makes heavy use of `IFileProvider` in locating views. Dotnet's publish functionality uses file providers and globbing patterns to specify which files should be published.

## Recommendations for use in apps

If your ASP.NET Core app requires file system access, you can request an instance of `IFileProvider` through dependency injection, and then use its methods to perform the access, as shown in this sample. This allows you to configure the provider once, when the app starts up, and reduces the number of implementation types your app instantiates.

# Host in ASP.NET Core

6/21/2018 • 2 minutes to read • [Edit Online](#)

.NET apps configure and launch a *host*. The host is responsible for app startup and lifetime management. Two host APIs are available for use:

- [Web Host](#) – Suitable for hosting web apps.
- [Generic Host](#) (ASP.NET Core 2.1 or later) – Suitable for hosting non-web apps (for example, apps that run background tasks). In a future release, the Generic Host will be suitable for hosting any kind of app, including web apps. The Generic Host will eventually replace the Web Host.

For hosting ASP.NET Core *web apps*, developers should use the Web Host based on [IWebHostBuilder](#). For hosting *non-web apps*, developers should use the Generic Host based on [HostBuilder](#).

# ASP.NET Core Web Host

7/6/2018 • 17 minutes to read • [Edit Online](#)

By [Luke Latham](#)

ASP.NET Core apps configure and launch a *host*. The host is responsible for app startup and lifetime management. At a minimum, the host configures a server and a request processing pipeline. This topic covers the ASP.NET Core Web Host ([IWebHostBuilder](#)), which is useful for hosting web apps. For coverage of the .NET Generic Host ([IHostBuilder](#)), see [.NET Generic Host](#).

## Set up a host

Create a host using an instance of [IWebHostBuilder](#). This is typically performed in the app's entry point, the `Main` method. In the project templates, `Main` is located in *Program.cs*. A typical *Program.cs* calls [CreateDefaultBuilder](#) to start setting up a host:

```
public class Program
{
    public static void Main(string[] args)
    {
        CreateWebHostBuilder(args).Build().Run();
    }

    public static IWebHostBuilder CreateWebHostBuilder(string[] args) =>
        WebHost.CreateDefaultBuilder(args)
            .UseStartup<Startup>();
}
```

`CreateDefaultBuilder` performs the following tasks:

- Configures [Kestrel](#) as the web server and configures the server using the app's hosting configuration providers. For the Kestrel default options, see [Kestrel web server implementation in ASP.NET Core](#).
- Sets the content root to the path returned by [Directory.GetCurrentDirectory](#).
- Loads [host configuration](#) from:
  - Environment variables prefixed with `ASPNETCORE_` (for example, `ASPNETCORE_ENVIRONMENT`).
  - Command-line arguments.
  - Loads app configuration from:
    - `appsettings.json`.
    - `appsettings.{Environment}.json`.
  - [User secrets](#) when the app runs in the `Development` environment using the entry assembly.
  - Environment variables.
  - Command-line arguments.
- Configures [logging](#) for console and debug output. Logging includes [log filtering](#) rules specified in a Logging configuration section of an `appsettings.json` or `appsettings.{Environment}.json` file.
- When running behind IIS, enables [IIS integration](#). Configures the base path and port the server listens on when using the [ASP.NET Core Module](#). The module creates a reverse proxy between IIS and Kestrel. Also configures the app to [capture startup errors](#). For the IIS default options, see [Host ASP.NET Core on Windows with IIS](#).
- Sets `ServiceProviderOptions.ValidateScopes` to `true` if the app's environment is Development. For more information, see [Scope validation](#).

The configuration defined by `CreateDefaultBuilder` can be overridden and augmented by `ConfigureAppConfiguration`, `ConfigureLogging`, and other methods and extension methods of `IWebHostBuilder`. A few examples follow:

- `ConfigureAppConfiguration` is used to specify additional `IConfiguration` for the app. The following `ConfigureAppConfiguration` call adds a delegate to include app configuration in the `appsettings.xml` file. `ConfigureAppConfiguration` may be called multiple times. Note that this configuration doesn't apply to the host (for example, server URLs or environment). See the [Host configuration values](#) section.

```
WebHost.CreateDefaultBuilder(args)
    .ConfigureAppConfiguration((hostingContext, config) =>
{
    config.AddXmlFile("appsettings.xml", optional: true, reloadOnChange: true);
})
...
...
```

- The following `ConfigureLogging` call adds a delegate to configure the minimum logging level (`SetMinimumLevel`) to `LogLevel.Warning`. This setting overrides the settings in `appsettings.Development.json` (`LogLevel.Debug`) and `appsettings.Production.json` (`LogLevel.Error`) configured by `CreateDefaultBuilder`. `ConfigureLogging` may be called multiple times.

```
WebHost.CreateDefaultBuilder(args)
    .ConfigureLogging(logging =>
{
    logging.SetMinimumLevel(LogLevel.Warning);
})
...
...
```

- The following call to `UseKestrel` overrides the default `Limits.MaxRequestBodySize` of 30,000,000 bytes established when Kestrel was configured by `CreateDefaultBuilder`:

```
WebHost.CreateDefaultBuilder(args)
    .UseKestrel(options =>
{
    options.Limits.MaxRequestBodySize = 20000000;
});
...
...
```

The `content root` determines where the host searches for content files, such as MVC view files. When the app is started from the project's root folder, the project's root folder is used as the content root. This is the default used in [Visual Studio](#) and the [dotnet new templates](#).

For more information on app configuration, see [Configuration in ASP.NET Core](#).

#### NOTE

As an alternative to using the static `CreateDefaultBuilder` method, creating a host from `WebHostBuilder` is a supported approach with ASP.NET Core 2.x. For more information, see the [ASP.NET Core 1.x tab](#).

Create a host using an instance of `WebHostBuilder`. Creating a host is typically performed in the app's entry point, the `Main` method. In the project templates, `Main` is located in `Program.cs`:

```

public class Program
{
    public static void Main(string[] args)
    {
        BuildWebHost(args).Run();
    }

    public static IWebHost BuildWebHost(string[] args) =>
        WebHost.CreateDefaultBuilder(args)
            .UseStartup<Startup>()
            .Build();
}

```

`WebHostBuilder` requires a [server that implements `IHostBuilder`](#). The built-in servers are [Kestrel](#) and [HTTP.sys](#) (prior to the release of ASP.NET Core 2.0, HTTP.sys was called [WebListener](#)). In this example, the [UseKestrel extension method](#) specifies the Kestrel server.

The [content root](#) determines where the host searches for content files, such as MVC view files. The default content root is obtained for `UseContentRoot` by [Directory.GetCurrentDirectory](#). When the app is started from the project's root folder, the project's root folder is used as the content root. This is the default used in [Visual Studio](#) and the [dotnet new templates](#).

To use IIS as a reverse proxy, call [UseIISIntegration](#) as part of building the host. `UseIISIntegration` doesn't configure a [server](#), like [UseKestrel](#) does. `UseIISIntegration` configures the base path and port the server listens on when using the [ASP.NET Core Module](#) to create a reverse proxy between Kestrel and IIS. To use IIS with ASP.NET Core, `UseKestrel` and `UseIISIntegration` must be specified. `UseIISIntegration` only activates when running behind IIS or IIS Express. For more information, see [ASP.NET Core Module](#) and [ASP.NET Core Module configuration reference](#).

A minimal implementation that configures a host (and an ASP.NET Core app) includes specifying a server and configuration of the app's request pipeline:

```

var host = new WebHostBuilder()
    .UseKestrel()
    .Configure(app =>
    {
        app.Run(context => context.Response.WriteAsync("Hello World!"));
    })
    .Build();

host.Run();

```

When setting up a host, [Configure](#) and [ConfigureServices](#) methods can be provided. If a `Startup` class is specified, it must define a `Configure` method. For more information, see [Application startup in ASP.NET Core](#). Multiple calls to `ConfigureServices` append to one another. Multiple calls to `Configure` or `UseStartup` on the `WebHostBuilder` replace previous settings.

## Host configuration values

`WebHostBuilder` relies on the following approaches to set the host configuration values:

- Host builder configuration, which includes environment variables with the format `ASPNETCORE_{configurationKey}`. For example, `ASPNETCORE_ENVIRONMENT`.
- Extensions such as [UseContentRoot](#) and [UseConfiguration](#) (see the [Override configuration](#) section).
- [UseSetting](#) and the associated key. When setting a value with `useSetting`, the value is set as a string regardless of the type.

The host uses whichever option sets a value last. For more information, see [Override configuration](#) in the next section.

### Application Key (Name)

The `IHostingEnvironment.ApplicationName` property is automatically set when `UseStartup` or `Configure` is called during host construction. The value is set to the name of the assembly containing the app's entry point. To set the value explicitly, use the `WebHostDefaults.ApplicationKey`:

**Key:** `applicationName`

**Type:** `string`

**Default:** The name of the assembly containing the app's entry point.

**Set using:** `UseSetting`

**Environment variable:** `ASPNETCORE_APPLICATIONKEY`

```
WebHost.CreateDefaultBuilder(args)
    .UseSetting(WebHostDefaults.ApplicationKey, "CustomApplicationName")
```

```
var host = new WebHostBuilder()
    .UseSetting("applicationName", "CustomApplicationName")
```

### Capture Startup Errors

This setting controls the capture of startup errors.

**Key:** `captureStartupErrors`

**Type:** `bool` (`true` or `1`)

**Default:** Defaults to `false` unless the app runs with Kestrel behind IIS, where the default is `true`.

**Set using:** `CaptureStartupErrors`

**Environment variable:** `ASPNETCORE_CAPTURESTARTUPERRORS`

When `false`, errors during startup result in the host exiting. When `true`, the host captures exceptions during startup and attempts to start the server.

```
WebHost.CreateDefaultBuilder(args)
    .CaptureStartupErrors(true)
```

```
var host = new WebHostBuilder()
    .CaptureStartupErrors(true)
```

### Content Root

This setting determines where ASP.NET Core begins searching for content files, such as MVC views.

**Key:** `contentRoot`

**Type:** `string`

**Default:** Defaults to the folder where the app assembly resides.

**Set using:** `UseContentRoot`

**Environment variable:** `ASPNETCORE_CONTENTROOT`

The content root is also used as the base path for the [Web Root setting](#). If the path doesn't exist, the host fails to start.

```
WebHost.CreateDefaultBuilder(args)
    .UseContentRoot("c:\\<content-root>")
```

```
var host = new WebHostBuilder()
    .UseContentRoot("c:\\<content-root>")
```

## Detailed Errors

Determines if detailed errors should be captured.

**Key:** detailedErrors

**Type:** bool (`true` or `1`)

**Default:** false

**Set using:** `UseSetting`

**Environment variable:** `ASPNETCORE_DETAILEDERRORS`

When enabled (or when the [Environment](#) is set to `Development`), the app captures detailed exceptions.

```
WebHost.CreateDefaultBuilder(args)
    .UseSetting(WebHostDefaults.DetailedErrorsKey, "true")
```

```
var host = new WebHostBuilder()
    .UseSetting(WebHostDefaults.DetailedErrorsKey, "true")
```

## Environment

Sets the app's environment.

**Key:** environment

**Type:** string

**Default:** Production

**Set using:** `UseEnvironment`

**Environment variable:** `ASPNETCORE_ENVIRONMENT`

The environment can be set to any value. Framework-defined values include `Development`, `Staging`, and `Production`. Values aren't case sensitive. By default, the *Environment* is read from the `ASPNETCORE_ENVIRONMENT` environment variable. When using [Visual Studio](#), environment variables may be set in the *launchSettings.json* file. For more information, see [Use multiple environments in ASP.NET Core](#).

```
WebHost.CreateDefaultBuilder(args)
    .UseEnvironment(EnvironmentName.Development)
```

```
var host = new WebHostBuilder()
    .UseEnvironment(EnvironmentName.Development)
```

## Hosting Startup Assemblies

Sets the app's hosting startup assemblies.

**Key:** hostingStartupAssemblies

**Type:** string

**Default:** Empty string

**Set using:** `UseSetting`

## **Environment variable:** ASPNETCORE\_HOSTINGSTARTUPASSEMBLIES

A semicolon-delimited string of hosting startup assemblies to load on startup.

Although the configuration value defaults to an empty string, the hosting startup assemblies always include the app's assembly. When hosting startup assemblies are provided, they're added to the app's assembly for loading when the app builds its common services during startup.

```
WebHost.CreateDefaultBuilder(args)
    .UseSetting(WebHostDefaults.HostingStartupAssembliesKey, "assembly1;assembly2")
```

## Prefer Hosting URLs

Indicates whether the host should listen on the URLs configured with the `WebHostBuilder` instead of those configured with the `IIServer` implementation.

**Key:** preferHostingUrls

**Type:** `bool` (`true` or `1`)

**Default:** true

**Set using:** `PreferHostingUrls`

**Environment variable:** ASPNETCORE\_PREFERHOSTINGURLS

```
WebHost.CreateDefaultBuilder(args)
    .PreferHostingUrls(false)
```

## Prevent Hosting Startup

Prevents the automatic loading of hosting startup assemblies, including hosting startup assemblies configured by the app's assembly. For more information, see [Enhance an app from an external assembly in ASP.NET Core with IHostingStartup](#).

**Key:** preventHostingStartup

**Type:** `bool` (`true` or `1`)

**Default:** false

**Set using:** `UseSetting`

**Environment variable:** ASPNETCORE\_PREVENTHOSTINGSTARTUP

```
WebHost.CreateDefaultBuilder(args)
    .UseSetting(WebHostDefaults.PreventHostingStartupKey, "true")
```

## Server URLs

Indicates the IP addresses or host addresses with ports and protocols that the server should listen on for requests.

**Key:** urls

**Type:** `string`

**Default:** `http://localhost:5000`

**Set using:** `UseUrls`

**Environment variable:** ASPNETCORE\_URLS

Set to a semicolon-separated (;) list of URL prefixes to which the server should respond. For example, `http://localhost:123`. Use "\*" to indicate that the server should listen for requests on any IP address or hostname using the specified port and protocol (for example, `http://*:5000`). The protocol (`http://` or `https://`) must be included with each URL. Supported formats vary between servers.

```
WebHost.CreateDefaultBuilder(args)
    .UseUrls("http://*:5000;http://localhost:5001;https://hostname:5002")
```

Kestrel has its own endpoint configuration API. For more information, see [Kestrel web server implementation in ASP.NET Core](#).

```
var host = new WebHostBuilder()
    .UseUrls("http://*:5000;http://localhost:5001;https://hostname:5002")
```

## Shutdown Timeout

Specifies the amount of time to wait for the web host to shut down.

**Key:** shutdownTimeoutSeconds

**Type:** *int*

**Default:** 5

**Set using:** `UseShutdownTimeout`

**Environment variable:** `ASPNETCORE_SHUTDOWNTIMEOUTSECONDS`

Although the key accepts an *int* with `UseSetting` (for example,

```
.UseSetting(WebHostDefaults.ShutdownTimeoutKey, "10"))
```

, the `UseShutdownTimeout` extension method takes a `TimeSpan`.

During the timeout period, hosting:

- Triggers [IApplicationLifetime.ApplicationStopping](#).
- Attempts to stop hosted services, logging any errors for services that fail to stop.

If the timeout period expires before all of the hosted services stop, any remaining active services are stopped when the app shuts down. The services stop even if they haven't finished processing. If services require additional time to stop, increase the timeout.

```
WebHost.CreateDefaultBuilder(args)
    .UseShutdownTimeout(TimeSpan.FromSeconds(10))
```

## Startup Assembly

Determines the assembly to search for the `Startup` class.

**Key:** startupAssembly

**Type:** *string*

**Default:** The app's assembly

**Set using:** `UseStartup`

**Environment variable:** `ASPNETCORE_STARTUPASSEMBLY`

The assembly by name (`string`) or type (`TStartup`) can be referenced. If multiple `useStartup` methods are called, the last one takes precedence.

```
WebHost.CreateDefaultBuilder(args)
    .UseStartup("StartupAssemblyName")
```

```
WebHost.CreateDefaultBuilder(args)
    .UseStartup<TStartup>()
```

```
var host = new WebHostBuilder()
    .UseStartup("StartupAssemblyName")
```

```
var host = new WebHostBuilder()
    .UseStartup<Startup>()
```

## Web Root

Sets the relative path to the app's static assets.

**Key:** webroot

**Type:** string

**Default:** If not specified, the default is "(Content Root)/wwwroot", if the path exists. If the path doesn't exist, then a no-op file provider is used.

**Set using:** `UseWebRoot`

**Environment variable:** `ASPNETCORE_WEBROOT`

```
WebHost.CreateDefaultBuilder(args)
    .UseWebRoot("public")
```

```
var host = new WebHostBuilder()
    .UseWebRoot("public")
```

## Override configuration

Use [Configuration](#) to configure the web host. In the following example, host configuration is optionally specified in a `hostsettings.json` file. Any configuration loaded from the `hostsettings.json` file may be overridden by command-line arguments. The built configuration (in `config`) is used to configure the host with [UseConfiguration](#).

`IWebHostBuilder` configuration is added to the app's configuration, but the converse isn't true—

`ConfigureAppConfiguration` doesn't affect the `IWebHostBuilder` configuration.

Overriding the configuration provided by `useUrls` with `hostsettings.json` config first, command-line argument config second:

```

public class Program
{
    public static void Main(string[] args)
    {
        CreateWebHostBuilder(args).Build().Run();
    }

    public static IWebHostBuilder CreateWebHostBuilder(string[] args)
    {
        var config = new ConfigurationBuilder()
            .SetBasePath(Directory.GetCurrentDirectory())
            .AddJsonFile("hostsettings.json", optional: true)
            .AddCommandLine(args)
            .Build();

        return WebHost.CreateDefaultBuilder(args)
            .UseUrls("http://*:5000")
            .UseConfiguration(config)
            .Configure(app =>
        {
            app.Run(context =>
                context.Response.WriteAsync("Hello, World!"));
        })
            .Build();
    }
}

```

*hostsettings.json:*

```
{
  urls: "http://*:5005"
}
```

Overriding the configuration provided by `useUrls` with *hostsettings.json* config first, command-line argument config second:

```

public class Program
{
    public static void Main(string[] args)
    {
        var config = new ConfigurationBuilder()
            .SetBasePath(Directory.GetCurrentDirectory())
            .AddJsonFile("hostsettings.json", optional: true)
            .AddCommandLine(args)
            .Build();

        var host = new WebHostBuilder()
            .UseUrls("http://*:5000")
            .UseConfiguration(config)
            .UseKestrel()
            .Configure(app =>
        {
            app.Run(context =>
                context.Response.WriteAsync("Hello, World!"));
        })
            .Build();

        host.Run();
    }
}

```

*hostsettings.json:*

```
{  
  urls: "http://*:5005"  
}
```

## NOTE

The `UseConfiguration` extension method isn't currently capable of parsing a configuration section returned by `GetSection` (for example, `.UseConfiguration(Configuration.GetSection("section"))`). The `GetSection` method filters the configuration keys to the section requested but leaves the section name on the keys (for example, `section:urls`, `section:environment`). The `UseConfiguration` method expects the keys to match the `WebHostBuilder` keys (for example, `urls`, `environment`). The presence of the section name on the keys prevents the section's values from configuring the host. This issue will be addressed in an upcoming release. For more information and workarounds, see [Passing configuration section into WebHostBuilder.UseConfiguration uses full keys](#).

`UseConfiguration` only copies keys from the provided `IConfiguration` to the host builder configuration. Therefore, setting `reloadOnChange: true` for JSON, INI, and XML settings files has no effect.

To specify the host run on a particular URL, the desired value can be passed in from a command prompt when executing `dotnet run`. The command-line argument overrides the `urls` value from the `hostsettings.json` file, and the server listens on port 8080:

```
dotnet run --urls "http://*:8080"
```

## Manage the host

### Run

The `Run` method starts the web app and blocks the calling thread until the host is shut down:

```
host.Run();
```

### Start

Run the host in a non-blocking manner by calling its `Start` method:

```
using (host)  
{  
  host.Start();  
  Console.ReadLine();  
}
```

If a list of URLs is passed to the `Start` method, it listens on the URLs specified:

```

var urls = new List<string>()
{
    "http://*:5000",
    "http://localhost:5001"
};

var host = new WebHostBuilder()
    .UseKestrel()
    .UseStartup<Startup>()
    .Start(urls.ToArray());

using (host)
{
    Console.ReadLine();
}

```

The app can initialize and start a new host using the pre-configured defaults of `CreateDefaultBuilder` using a static convenience method. These methods start the server without console output and with `WaitForShutdown` wait for a break (Ctrl-C/SIGINT or SIGTERM):

### **Start(RequestDelegate app)**

Start with a `RequestDelegate` :

```

using (var host = WebHost.Start(app => app.Response.WriteAsync("Hello, World!")))
{
    Console.WriteLine("Use Ctrl-C to shutdown the host...");
    host.WaitForShutdown();
}

```

Make a request in the browser to `http://localhost:5000` to receive the response "Hello World!" `WaitForShutdown` blocks until a break (Ctrl-C/SIGINT or SIGTERM) is issued. The app displays the `Console.WriteLine` message and waits for a keypress to exit.

### **Start(string url, RequestDelegate app)**

Start with a URL and `RequestDelegate` :

```

using (var host = WebHost.Start("http://localhost:8080", app => app.Response.WriteAsync("Hello, World!")))
{
    Console.WriteLine("Use Ctrl-C to shutdown the host...");
    host.WaitForShutdown();
}

```

Produces the same result as **Start(RequestDelegate app)**, except the app responds on `http://localhost:8080`.

### **Start(Action<IRouteBuilder> routeBuilder)**

Use an instance of `IRouteBuilder` ([Microsoft.AspNetCore.Routing](#)) to use routing middleware:

```

using (var host = WebHost.Start(router => router
    .MapGet("hello/{name}", (req, res, data) =>
        res.WriteAsync($"Hello, {data.Values["name"]}!"))
    .MapGet("buenosdias/{name}", (req, res, data) =>
        res.WriteAsync($"Buenos dias, {data.Values["name"]}!"))
    .MapGet("throw/{message?}", (req, res, data) =>
        throw new Exception((string)data.Values["message"] ?? "Uh oh!"))
    .MapGet("{greeting}/{name}", (req, res, data) =>
        res.WriteAsync($"{data.Values["greeting"]}, {data.Values["name"]}!"))
    .MapGet("", (req, res, data) => res.WriteAsync("Hello, World!"))))
{
    Console.WriteLine("Use Ctrl-C to shutdown the host...");
    host.WaitForShutdown();
}

```

Use the following browser requests with the example:

REQUEST	RESPONSE
<code>http://localhost:5000/hello/Martin</code>	Hello, Martin!
<code>http://localhost:5000/buenosdias/Catrina</code>	Buenos dias, Catrina!
<code>http://localhost:5000/throw/ooops!</code>	Throws an exception with string "ooops!"
<code>http://localhost:5000/throw</code>	Throws an exception with string "Uh oh!"
<code>http://localhost:5000/Sante/Kevin</code>	Sante, Kevin!
<code>http://localhost:5000</code>	Hello World!

`WaitForShutdown` blocks until a break (Ctrl-C/SIGINT or SIGTERM) is issued. The app displays the `Console.WriteLine` message and waits for a keypress to exit.

### **Start(string url, Action<IRouteBuilder> routeBuilder)**

Use a URL and an instance of `IRouteBuilder`:

```

using (var host = WebHost.Start("http://localhost:8080", router => router
    .MapGet("hello/{name}", (req, res, data) =>
        res.WriteAsync($"Hello, {data.Values["name"]}!"))
    .MapGet("buenosdias/{name}", (req, res, data) =>
        res.WriteAsync($"Buenos dias, {data.Values["name"]}!"))
    .MapGet("throw/{message?}", (req, res, data) =>
        throw new Exception((string)data.Values["message"] ?? "Uh oh!"))
    .MapGet("{greeting}/{name}", (req, res, data) =>
        res.WriteAsync($"{data.Values["greeting"]}, {data.Values["name"]}!"))
    .MapGet("", (req, res, data) => res.WriteAsync("Hello, World!"))))
{
    Console.WriteLine("Use Ctrl-C to shut down the host...");
    host.WaitForShutdown();
}

```

Produces the same result as **Start(Action<IRouteBuilder> routeBuilder)**, except the app responds at `http://localhost:8080`.

### **StartWith(Action<IApplicationBuilder> app)**

Provide a delegate to configure an `IApplicationBuilder`:

```
using (var host = WebHost.StartWith(app =>
    app.Use(next =>
    {
        return async context =>
        {
            await context.Response.WriteAsync("Hello World!");
        };
    }));
{
    Console.WriteLine("Use Ctrl-C to shut down the host...");
    host.WaitForShutdown();
}
```

Make a request in the browser to `http://localhost:5000` to receive the response "Hello World!" `WaitForShutdown` blocks until a break (Ctrl-C/SIGINT or SIGTERM) is issued. The app displays the `Console.WriteLine` message and waits for a keypress to exit.

### **StartWith(string url, Action<IApplicationBuilder> app)**

Provide a URL and a delegate to configure an `IApplicationBuilder`:

```
using (var host = WebHost.StartWith("http://localhost:8080", app =>
    app.Use(next =>
    {
        return async context =>
        {
            await context.Response.WriteAsync("Hello World!");
        };
    }));
{
    Console.WriteLine("Use Ctrl-C to shut down the host...");
    host.WaitForShutdown();
}
```

Produces the same result as **StartWith(Action<IApplicationBuilder> app)**, except the app responds on `http://localhost:8080`.

### **Run**

The `Run` method starts the web app and blocks the calling thread until the host is shut down:

```
host.Run();
```

### **Start**

Run the host in a non-blocking manner by calling its `Start` method:

```
using (host)
{
    host.Start();
    Console.ReadLine();
}
```

If a list of URLs is passed to the `Start` method, it listens on the URLs specified:

```
var urls = new List<string>()
{
    "http://*:5000",
    "http://localhost:5001"
};

var host = new WebHostBuilder()
    .UseKestrel()
    .UseStartup<Startup>()
    .Start(urls.ToArray());

using (host)
{
    Console.ReadLine();
}
```

## IHostingEnvironment interface

The [IHostingEnvironment interface](#) provides information about the app's web hosting environment. Use [constructor injection](#) to obtain the `IHostingEnvironment` in order to use its properties and extension methods:

```
public class CustomFileReader
{
    private readonly IHostingEnvironment _env;

    public CustomFileReader(IHostingEnvironment env)
    {
        _env = env;
    }

    public string ReadFile(string filePath)
    {
        var fileProvider = _env.WebRootFileProvider;
        // Process the file here
    }
}
```

A [convention-based approach](#) can be used to configure the app at startup based on the environment. Alternatively, inject the `IHostingEnvironment` into the `Startup` constructor for use in `ConfigureServices`:

```

public class Startup
{
    public Startup(IHostingEnvironment env)
    {
        HostingEnvironment = env;
    }

    public IHostingEnvironment HostingEnvironment { get; }

    public void ConfigureServices(IServiceCollection services)
    {
        if (HostingEnvironment.IsDevelopment())
        {
            // Development configuration
        }
        else
        {
            // Staging/Production configuration
        }
    }

    var contentRootPath = HostingEnvironment.ContentRootPath;
}
}

```

#### NOTE

In addition to the `IsDevelopment` extension method, `IHostingEnvironment` offers `IsStaging`, `IsProduction`, and `IsEnvironment(string environmentName)` methods. For more information, see [Use multiple environments in ASP.NET Core](#).

The `IHostingEnvironment` service can also be injected directly into the `Configure` method for setting up the processing pipeline:

```

public void Configure(IApplicationBuilder app, IHostingEnvironment env)
{
    if (env.IsDevelopment())
    {
        // In Development, use the developer exception page
        app.UseDeveloperExceptionPage();
    }
    else
    {
        // In Staging/Production, route exceptions to /error
        app.UseExceptionHandler("/error");
    }

    var contentRootPath = env.ContentRootPath;
}

```

`IHostingEnvironment` can be injected into the `Invoke` method when creating custom [middleware](#):

```

public async Task Invoke(HttpContext context, IHostingEnvironment env)
{
    if (env.IsDevelopment())
    {
        // Configure middleware for Development
    }
    else
    {
        // Configure middleware for Staging/Production
    }

    var contentRootPath = env.ContentRootPath;
}

```

## IApplicationLifetime interface

[IApplicationLifetime](#) allows for post-startup and shutdown activities. Three properties on the interface are cancellation tokens used to register `Action` methods that define startup and shutdown events.

CANCELLATION TOKEN	TRIGGERED WHEN...
<a href="#">ApplicationStarted</a>	The host has fully started.
<a href="#">ApplicationStopped</a>	The host is completing a graceful shutdown. All requests should be processed. Shutdown blocks until this event completes.
<a href="#">ApplicationStopping</a>	The host is performing a graceful shutdown. Requests may still be processing. Shutdown blocks until this event completes.

```

public class Startup
{
    public void Configure(IApplicationBuilder app, IApplicationLifetime appLifetime)
    {
        appLifetime.ApplicationStarted.Register(OnStarted);
        appLifetime.ApplicationStopping.Register(OnStopping);
        appLifetime.ApplicationStopped.Register(OnStopped);

        Console.CancelKeyPress += (sender, eventArgs) =>
        {
            appLifetime.StopApplication();
            // Don't terminate the process immediately, wait for the Main thread to exit gracefully.
            eventArgs.Cancel = true;
        };
    }

    private void OnStarted()
    {
        // Perform post-startup activities here
    }

    private void OnStopping()
    {
        // Perform on-stopping activities here
    }

    private void OnStopped()
    {
        // Perform post-stopped activities here
    }
}

```

[StopApplication](#) requests termination of the app. The following class uses [StopApplication](#) to gracefully shut down an app when the class's [Shutdown](#) method is called:

```

public class MyClass
{
    private readonly IApplicationLifetime _appLifetime;

    public MyClass(IApplicationLifetime appLifetime)
    {
        _appLifetime = appLifetime;
    }

    public void Shutdown()
    {
        _appLifetime.StopApplication();
    }
}

```

## Scope validation

[CreateDefaultBuilder](#) sets [ServiceProviderOptions.ValidateScopes](#) to [true](#) if the app's environment is Development.

When [ValidateScopes](#) is set to [true](#), the default service provider performs checks to verify that:

- Scoped services aren't directly or indirectly resolved from the root service provider.
- Scoped services aren't directly or indirectly injected into singletons.

The root service provider is created when [BuildServiceProvider](#) is called. The root service provider's lifetime corresponds to the app/server's lifetime when the provider starts with the app and is disposed when the app shuts

down.

Scoped services are disposed by the container that created them. If a scoped service is created in the root container, the service's lifetime is effectively promoted to singleton because it's only disposed by the root container when app/server is shut down. Validating service scopes catches these situations when `BuildServiceProvider` is called.

To always validate scopes, including in the Production environment, configure the `ServiceProviderOptions` with `UseDefaultServiceProvider` on the host builder:

```
WebHost.CreateDefaultBuilder(args)
    .UseDefaultServiceProvider((context, options) => {
        options.ValidateScopes = true;
    })
```

## Troubleshooting System.ArgumentException

The following only applies to ASP.NET Core 2.0 apps when the app doesn't call `UseStartup` or `Configure`.

A host may be built by injecting `IStartup` directly into the dependency injection container rather than calling `UseStartup` or `Configure`:

```
services.AddSingleton<IStartup, Startup>();
```

If the host is built this way, the following error may occur:

```
Unhandled Exception: System.ArgumentException: A valid non-empty application name must be provided.
```

This occurs because the app name (the name of the current assembly) is required to scan for `HostingStartupAttributes`. If the app manually injects `IStartup` into the dependency injection container, add the following call to `WebHostBuilder` with the assembly name specified:

```
WebHost.CreateDefaultBuilder(args)
    .UseSetting("applicationName", "AssemblyName")
```

Alternatively, add a dummy `Configure` to the `WebHostBuilder`, which sets the app name automatically:

```
WebHost.CreateDefaultBuilder(args)
    .Configure(_ => { })
```

For more information, see [Announcements: Microsoft.Extensions.PlatformAbstractions has been removed \(comment\)](#) and the [StartupInjection sample](#).

# .NET Generic Host

7/6/2018 • 10 minutes to read • [Edit Online](#)

By [Luke Latham](#)

.NET apps configure and launch a *host*. The host is responsible for app startup and lifetime management. This topic covers the ASP.NET Core Generic Host ([HostBuilder](#)), which is useful for hosting apps that don't process HTTP requests. For coverage of the Web Host ([WebHostBuilder](#)), see [ASP.NET Core Web Host](#).

The goal of the Generic Host is to decouple the HTTP pipeline from the Web Host API to enable a wider array of host scenarios. Messaging, background tasks, and other non-HTTP workloads based on the Generic Host benefit from cross-cutting capabilities, such as configuration, dependency injection (DI), and logging.

The Generic Host is new in ASP.NET Core 2.1 and isn't suitable for web hosting scenarios. For web hosting scenarios, use the [Web Host](#). The Generic Host is under development to replace the Web Host in a future release and act as the primary host API in both HTTP and non-HTTP scenarios.

[View or download sample code \(how to download\)](#)

When running the sample app in [Visual Studio Code](#), use an *external or integrated terminal*. Don't run the sample in an `internalConsole`.

To set the console in Visual Studio Code:

1. Open the `.vscode/launch.json` file.
2. In the **.NET Core Launch (console)** configuration, locate the **console** entry. Set the value to either `externalTerminal` or `integratedTerminal`.

## Introduction

The Generic Host library is available in the [Microsoft.Extensions.Hosting namespace](#) and provided by the [Microsoft.Extensions.Hosting package](#). The `Microsoft.Extensions.Hosting` package is included in the [Microsoft.AspNetCore.App metapackage](#) (ASP.NET Core 2.1 or later).

`IHostedService` is the entry point to code execution. Each `IHostedService` implementation is executed in the order of [service registration in ConfigureServices](#). `StartAsync` is called on each `IHostedService` when the host starts, and `StopAsync` is called in reverse registration order when the host shuts down gracefully.

## Set up a host

`IHostBuilder` is the main component that libraries and apps use to initialize, build, and run the host:

```
public static async Task Main(string[] args)
{
    var host = new HostBuilder()
        .Build();

    await host.RunAsync();
}
```

## Host configuration

`HostBuilder` relies on the following approaches to set the host configuration values:

- Configuration builder
- Extension method configuration

## Configuration builder

Host builder configuration is created by calling [ConfigureHostConfiguration](#) on the [IHostBuilder](#) implementation.

`ConfigureHostConfiguration` uses an  [IConfigurationBuilder](#) to create an  [IConfiguration](#) for the host. The configuration builder initializes the [IHostingEnvironment](#) for use in the app's build process.

Environment variable configuration isn't added by default. Call [AddEnvironmentVariables](#) on the host builder to configure the host from environment variables. `AddEnvironmentVariables` accepts an optional user-defined prefix. The sample app uses a prefix of `PREFIX_`. The prefix is removed when the environment variables are read. When the sample app's host is configured, the environment variable value for `PREFIX_ENVIRONMENT` becomes the host configuration value for the `environment` key.

During development when using [Visual Studio](#) or running an app with `dotnet run`, environment variables may be set in the *Properties/launchSettings.json* file. In [Visual Studio Code](#), environment variables may be set in the *.vscode/launch.json* file during development. For more information, see [Use multiple environments in ASP.NET Core](#).

`ConfigureHostConfiguration` can be called multiple times with additive results. The host uses whichever option sets a value last.

*hostsettings.json*:

```
{
  "environment": "Development"
}
```

Example `HostBuilder` configuration using `ConfigureHostConfiguration`:

```
var host = new HostBuilder()
    .ConfigureHostConfiguration(configHost =>
    {
        configHost.SetBasePath(Directory.GetCurrentDirectory());
        configHost.AddJsonFile("hostsettings.json", optional: true);
        configHost.AddEnvironmentVariables(prefix: "PREFIX_");
        configHost.AddCommandLine(args);
    })
}
```

### NOTE

The [AddConfiguration](#) extension method isn't currently capable of parsing a configuration section returned by [GetSection](#) (for example, `.AddConfiguration(Configuration.GetSection("section"))`). The `GetSection` method filters the configuration keys to the section requested but leaves the section name on the keys (for example, `section:environment`). The `AddConfiguration` method expects the keys to match the `HostBuilder` keys (for example, `environment`). The presence of the section name on the keys prevents the section's values from configuring the host. This issue will be addressed in an upcoming release. For more information and workarounds, see [Passing configuration section into WebHostBuilder.UseConfiguration uses full keys](#).

## Extension method configuration

Extension methods are called on the `IHostBuilder` implementation to configure the content root and the environment.

### Application Key (Name)

The [IHostingEnvironment.ApplicationName](#) property is set from host configuration during host construction. To

set the value explicitly, use the [HostDefaults.ApplicationKey](#):

**Key:** applicationName

**Type:** string

**Default:** The name of the assembly containing the app's entry point.

**Set using:** [UseSetting](#)

**Environment variable:** <PREFIX>APPLICATIONKEY ( <PREFIX> is [optional and user-defined](#))

```
WebHost.CreateDefaultBuilder(args)
    .UseSetting(WebHostDefaults.ApplicationKey, "CustomApplicationName")
```

#### Content Root

This setting determines where the host begins searching for content files.

**Key:** contentRoot

**Type:** string

**Default:** Defaults to the folder where the app assembly resides.

**Set using:** [UseContentRoot](#)

**Environment variable:** <PREFIX>CONTENTROOT ( <PREFIX> is [optional and user-defined](#))

If the path doesn't exist, the host fails to start.

```
var host = new HostBuilder()
    .UseContentRoot("c:\\<content-root>")
```

#### Environment

Sets the app's [environment](#).

**Key:** environment

**Type:** string

**Default:** Production

**Set using:** [UseEnvironment](#)

**Environment variable:** <PREFIX>ENVIRONMENT ( <PREFIX> is [optional and user-defined](#))

The environment can be set to any value. Framework-defined values include [Development](#), [Staging](#), and [Production](#). Values aren't case sensitive.

```
var host = new HostBuilder()
    .UseEnvironment(EnvironmentName.Development)
```

## ConfigureAppConfiguration

App builder configuration is created by calling [ConfigureAppConfiguration](#) on the [IHostBuilder](#) implementation.

[ConfigureAppConfiguration](#) uses an [IConfigurationBuilder](#) to create an [IConfiguration](#) for the app.

[ConfigureAppConfiguration](#) can be called multiple times with additive results. The app uses whichever option sets a value last. The configuration created by [ConfigureAppConfiguration](#) is available at [HostBuilderContext.Configuration](#) for subsequent operations and in [Services](#).

Example app configuration using [ConfigureAppConfiguration](#):

```

var host = new HostBuilder()
    .ConfigureAppConfiguration((hostContext, configApp) =>
{
    configApp.SetBasePath(Directory.GetCurrentDirectory());
    configApp.AddJsonFile("appsettings.json", optional: true);
    configApp.AddJsonFile(
        $"appsettings.{hostContext.HostingEnvironment.EnvironmentName}.json",
        optional: true);
    configApp.AddEnvironmentVariables(prefix: "PREFIX_");
    configApp.AddCommandLine(args);
})

```

*appsettings.json:*

```
{
    "Logging": {
        "LogLevel": {
            "Default": "Warning"
        }
    },
    "AllowedHosts": "*"
}
```

*appsettings.Development.json:*

```
{
    "Logging": {
        "LogLevel": {
            "Default": "Debug",
            "System": "Information",
            "Microsoft": "Information"
        }
    }
}
```

*appsettings.Production.json:*

```
{
    "Logging": {
        "LogLevel": {
            "Default": "Error",
            "System": "Information",
            "Microsoft": "Information"
        }
    }
}
```

#### NOTE

The [AddConfiguration](#) extension method isn't currently capable of parsing a configuration section returned by [GetSection](#) (for example, `.AddConfiguration(Configuration.GetSection("section"))`). The [GetSection](#) method filters the configuration keys to the section requested but leaves the section name on the keys (for example, `section:Logging:LogLevel:Default`). The [AddConfiguration](#) method expects an exact match to configuration keys (for example, `Logging:LogLevel:Default`). The presence of the section name on the keys prevents the section's values from configuring the app. This issue will be addressed in an upcoming release. For more information and workarounds, see [Passing configuration section into WebHostBuilder.UseConfiguration uses full keys](#).

To move settings files to the output directory, specify the settings files as [MSBuild project items](#) in the project file.

The sample app moves its JSON app settings files and `hostsettings.json` with the following <Content> item:

```
<ItemGroup>
<Content Include="**\*.json" CopyToOutputDirectory="PreserveNewest" />
</ItemGroup>
```

## ConfigureServices

[ConfigureServices](#) adds services to the app's dependency injection container. `ConfigureServices` can be called multiple times with additive results.

A hosted service is a class with background task logic that implements the [IHostedService](#) interface. For more information, see [Background tasks with hosted services in ASP.NET Core](#).

The [sample app](#) uses the `AddHostedService` extension method to add a service for lifetime events, `LifetimeEventsHostedService`, and a timed background task, `TimedHostedService`, to the app:

```
var host = new HostBuilder()
    .ConfigureServices((hostContext, services) =>
{
    services.AddLogging();
    services.AddHostedService<LifetimeEventsHostedService>();
    services.AddHostedService<TimedHostedService>();
})
```

## ConfigureLogging

[ConfigureLogging](#) adds a delegate for configuring the provided [ILoggingBuilder](#). `ConfigureLogging` may be called multiple times with additive results.

```
var host = new HostBuilder()
    .ConfigureLogging((hostContext, configLogging) =>
{
    configLogging.AddConsole();
    configLogging.AddDebug();
})
```

### UseConsoleLifetime

[UseConsoleLifetime](#) listens for `ctrl+c` /SIGINT or SIGTERM and calls [StopApplication](#) to start the shutdown process. `UseConsoleLifetime` unblocks extensions such as [RunAsync](#) and [WaitForShutdownAsync](#).

[ConsoleLifetime](#) is pre-registered as the default lifetime implementation. The last lifetime registered is used.

```
var host = new HostBuilder()
    .UseConsoleLifetime()
```

## Container configuration

To support plugging in other containers, the host can accept an [IServiceProviderFactory](#). Providing a factory isn't part of the DI container registration but is instead a host intrinsic used to create the concrete DI container.

[UseServiceProviderFactory\(IServiceProviderFactory<TContainerBuilder>\)](#) overrides the default factory used to create the app's service provider.

Custom container configuration is managed by the [ConfigureContainer](#) method. `ConfigureContainer` provides a

strongly-typed experience for configuring the container on top of the underlying host API. `ConfigureContainer` can be called multiple times with additive results.

Create a service container for the app:

```
namespace GenericHostSample
{
    internal class ServiceContainer
    {
    }
}
```

Provide a service container factory:

```
using System;
using Microsoft.Extensions.DependencyInjection;

namespace GenericHostSample
{
    internal class ServiceContainerFactory : IServiceProviderFactory<MyContainer>
    {
        public ServiceContainer CreateBuilder(IServiceCollection services)
        {
            return new ServiceContainer();
        }

        public IServiceProvider CreateServiceProvider(ServiceContainer containerBuilder)
        {
            throw new NotImplementedException();
        }
    }
}
```

Use the factory and configure the custom service container for the app:

```
var host = new HostBuilder()
    .UseServiceProviderFactory<ServiceContainer>(new ServiceContainerFactory())
    .ConfigureContainer<ServiceContainer>((hostContext, container) =>
{
})
```

## Extensibility

Host extensibility is performed with extension methods on `IHostBuilder`. The following example shows how an extension method extends an `IHostBuilder` implementation with [RabbitMQ](#). The extension method (elsewhere in the app) registers a RabbitMQ `IHostedService`:

```
// UseRabbitMq is an extension method that sets up RabbitMQ to handle incoming
// messages.
var host = new HostBuilder()
    .UseRabbitMq<MyMessageHandler>()
    .Build();

await host.StartAsync();
```

## Manage the host

The `IHost` implementation is responsible for starting and stopping the `IHostedService` implementations that are

registered in the service container.

## Run

[Run](#) runs the app and blocks the calling thread until the host is shut down:

```
public class Program
{
    public void Main(string[] args)
    {
        var host = new HostBuilder()
            .Build();

        host.Run();
    }
}
```

## RunAsync

[RunAsync](#) runs the app and returns a `Task` that completes when the cancellation token or shutdown is triggered:

```
public class Program
{
    public static async Task Main(string[] args)
    {
        var host = new HostBuilder()
            .Build();

        await host.RunAsync();
    }
}
```

## RunConsoleAsync

[RunConsoleAsync](#) enables console support, builds and starts the host, and waits for `Ctrl+C` /SIGINT or SIGTERM to shut down.

```
public class Program
{
    public static async Task Main(string[] args)
    {
        var hostBuilder = new HostBuilder();

        await hostBuilder.RunConsoleAsync();
    }
}
```

## Start and StopAsync

[Start](#) starts the host synchronously.

[StopAsync\(TimeSpan\)](#) attempts to stop the host within the provided timeout.

```

public class Program
{
    public static async Task Main(string[] args)
    {
        var host = new HostBuilder()
            .Build();

        using (host)
        {
            host.Start();

            await host.StopAsync(TimeSpan.FromSeconds(5));
        }
    }
}

```

## StartAsync and StopAsync

[StartAsync](#) starts the app.

[StopAsync](#) stops the app.

```

public class Program
{
    public static async Task Main(string[] args)
    {
        var host = new HostBuilder()
            .Build();

        using (host)
        {
            await host.StartAsync();

            await host.StopAsync();
        }
    }
}

```

## WaitForShutdown

[WaitForShutdown](#) is triggered via the [IHostLifetime](#), such as [ConsoleLifetime](#) (listens for [Ctrl+C](#) /SIGINT or SIGTERM). [WaitForShutdown](#) calls [StopAsync](#).

```

public class Program
{
    public void Main(string[] args)
    {
        var host = new HostBuilder()
            .Build();

        using (host)
        {
            host.Start();

            host.WaitForShutdown();
        }
    }
}

```

## WaitForShutdownAsync

[WaitForShutdownAsync](#) returns a [Task](#) that completes when shutdown is triggered via the given token and calls [StopAsync](#).

```
public class Program
{
    public static async Task Main(string[] args)
    {
        var host = new HostBuilder()
            .Build();

        using (host)
        {
            await host.StartAsync();

            await host.WaitForShutdownAsync();
        }
    }
}
```

## External control

External control of the host can be achieved using methods that can be called externally:

```
public class Program
{
    private IHost _host;

    public Program()
    {
        _host = new HostBuilder()
            .Build();
    }

    public async Task StartAsync()
    {
        _host.StartAsync();
    }

    public async Task StopAsync()
    {
        using (_host)
        {
            await _host.StopAsync(TimeSpan.FromSeconds(5));
        }
    }
}
```

`IHostLifetime.WaitForStartAsync` is called at the start of `StartAsync`, which waits until it's complete before continuing. This can be used to delay startup until signaled by an external event.

## IHostingEnvironment interface

`IHostingEnvironment` provides information about the app's hosting environment. Use [constructor injection](#) to obtain the `IHostingEnvironment` in order to use its properties and extension methods:

```

public class MyClass
{
    private readonly IHostingEnvironment _env;

    public MyClass(IHostingEnvironment env)
    {
        _env = env;
    }

    public void DoSomething()
    {
        var environmentName = _env.EnvironmentName;
    }
}

```

For more information, see [Use multiple environments in ASP.NET Core](#).

## IApplicationLifetime interface

[IApplicationLifetime](#) allows for post-startup and shutdown activities, including graceful shutdown requests. Three properties on the interface are cancellation tokens used to register `Action` methods that define startup and shutdown events.

CANCELLATION TOKEN	TRIGGERED WHEN...
<a href="#">ApplicationStarted</a>	The host has fully started.
<a href="#">ApplicationStopped</a>	The host is completing a graceful shutdown. All requests should be processed. Shutdown blocks until this event completes.
<a href="#">ApplicationStopping</a>	The host is performing a graceful shutdown. Requests may still be processing. Shutdown blocks until this event completes.

Constructor-inject the `IApplicationLifetime` service into any class. The [sample app](#) uses constructor injection into a `LifetimeEventsHostedService` class (an `IHostedService` implementation) to register the events.

*LifetimeEventsHostedService.cs:*

```

internal class LifetimeEventsHostedService : IHostedService
{
    private readonly ILogger _logger;
    private readonly IApplicationLifetime _appLifetime;

    public LifetimeEventsHostedService(
        ILogger<LifetimeEventsHostedService> logger, IApplicationLifetime appLifetime)
    {
        _logger = logger;
        _appLifetime = appLifetime;
    }

    public Task StartAsync(CancellationToken cancellationToken)
    {
        _appLifetime.ApplicationStarted.Register(OnStarted);
        _appLifetime.ApplicationStopping.Register(OnStopping);
        _appLifetime.ApplicationStopped.Register(OnStopped);

        return Task.CompletedTask;
    }

    public Task StopAsync(CancellationToken cancellationToken)
    {
        return Task.CompletedTask;
    }

    private void OnStarted()
    {
        _logger.LogInformation("OnStarted has been called.");

        // Perform post-startup activities here
    }

    private void OnStopping()
    {
        _logger.LogInformation("OnStopping has been called.");

        // Perform on-stopping activities here
    }

    private void OnStopped()
    {
        _logger.LogInformation("OnStopped has been called.");

        // Perform post-stopped activities here
    }
}

```

[StopApplication](#) requests termination of the app. The following class uses `StopApplication` to gracefully shut down an app when the class's `Shutdown` method is called:

```
public class MyClass
{
    private readonly IApplicationLifetime _appLifetime;

    public MyClass(IApplicationLifetime appLifetime)
    {
        _appLifetime = appLifetime;
    }

    public void Shutdown()
    {
        _appLifetime.StopApplication();
    }
}
```

# Background tasks with hosted services in ASP.NET Core

6/21/2018 • 4 minutes to read • [Edit Online](#)

By [Luke Latham](#)

In ASP.NET Core, background tasks can be implemented as *hosted services*. A hosted service is a class with background task logic that implements the [IHostedService](#) interface. This topic provides three hosted service examples:

- Background task that runs on a timer.
- Hosted service that activates a scoped service. The scoped service can use dependency injection.
- Queued background tasks that run sequentially.

[View or download sample code \(how to download\)](#)

The sample app is provided in two versions:

- Web Host – The Web Host is useful for hosting web apps. The example code shown in this topic is from the Web Host version of the sample. For more information, see the [Web Host](#) topic.
- Generic Host – The Generic Host is new in ASP.NET Core 2.1. For more information, see the [Generic Host](#) topic.

## IHostedService interface

Hosted services implement the [IHostedService](#) interface. The interface defines two methods for objects that are managed by the host:

- [StartAsync\(CancellationToken\)](#) - Called after the server has started and [IAplicationLifetime.ApplicationStarted](#) is triggered. `StartAsync` contains the logic to start the background task.
- [StopAsync\(CancellationToken\)](#) - Triggered when the host is performing a graceful shutdown. `StopAsync` contains the logic to end the background task and dispose of any unmanaged resources. If the app shuts down unexpectedly (for example, the app's process fails), `StopAsync` might not be called.

The hosted service is activated once at app startup and gracefully shutdown at app shutdown. When [IDisposable](#) is implemented, resources can be disposed when the service container is disposed. If an error is thrown during background task execution, `Dispose` should be called even if `StopAsync` isn't called.

## Timed background tasks

A timed background task makes use of the [System.Threading.Timer](#) class. The timer triggers the task's `Dowork` method. The timer is disabled on `StopAsync` and disposed when the service container is disposed on `Dispose`:

```

internal class TimedHostedService : IHostedService, IDisposable
{
    private readonly ILogger _logger;
    private Timer _timer;

    public TimedHostedService(ILogger<TimedHostedService> logger)
    {
        _logger = logger;
    }

    public Task StartAsync(CancellationToken cancellationToken)
    {
        _logger.LogInformation("Timed Background Service is starting.");

        _timer = new Timer(DoWork, null, TimeSpan.Zero,
            TimeSpan.FromSeconds(5));

        return Task.CompletedTask;
    }

    private void DoWork(object state)
    {
        _logger.LogInformation("Timed Background Service is working.");
    }

    public Task StopAsync(CancellationToken cancellationToken)
    {
        _logger.LogInformation("Timed Background Service is stopping.");

        _timer?.Change(Timeout.Infinite, 0);

        return Task.CompletedTask;
    }

    public void Dispose()
    {
        _timer?.Dispose();
    }
}

```

The service is registered in `Startup.ConfigureServices` with the `AddHostedService` extension method:

```
services.AddHostedService<TimedHostedService>();
```

The service is registered in `Startup.ConfigureServices`:

```
services.AddSingleton<IHostedService, TimedHostedService>();
```

## Consuming a scoped service in a background task

To use scoped services within an `IHostedService`, create a scope. No scope is created for a hosted service by default.

The scoped background task service contains the background task's logic. In the following example, `ILogger` is injected into the service:

```
internal interface IScopedProcessingService
{
    void DoWork();
}

internal class ScopedProcessingService : IScopedProcessingService
{
    private readonly ILogger _logger;

    public ScopedProcessingService(ILogger<ScopedProcessingService> logger)
    {
        _logger = logger;
    }

    public void DoWork()
    {
        _logger.LogInformation("Scoped Processing Service is working.");
    }
}
```

The hosted service creates a scope to resolve the scoped background task service to call its `DoWork` method:

```

internal class ConsumeScopedServiceHostedService : IHostedService
{
    private readonly ILogger _logger;

    public ConsumeScopedServiceHostedService(IServiceProvider services,
        ILogger<ConsumeScopedServiceHostedService> logger)
    {
        Services = services;
        _logger = logger;
    }

    public IServiceProvider Services { get; }

    public Task StartAsync(CancellationToken cancellationToken)
    {
        _logger.LogInformation(
            "Consume Scoped Service Hosted Service is starting.");

        DoWork();

        return Task.CompletedTask;
    }

    private void DoWork()
    {
        _logger.LogInformation(
            "Consume Scoped Service Hosted Service is working.");

        using (var scope = Services.CreateScope())
        {
            var scopedProcessingService =
                scope.ServiceProvider
                    .GetRequiredService<IScopedProcessingService>();

            scopedProcessingService.DoWork();
        }
    }

    public Task StopAsync(CancellationToken cancellationToken)
    {
        _logger.LogInformation(
            "Consume Scoped Service Hosted Service is stopping.");

        return Task.CompletedTask;
    }
}

```

The services are registered in `Startup.ConfigureServices`. The `IHostedService` implementation is registered with the `AddHostedService` extension method:

```

services.AddHostedService<ConsumeScopedServiceHostedService>();
services.AddScoped<IScopedProcessingService, ScopedProcessingService>();

```

The services are registered in `Startup.ConfigureServices`:

```

services.AddSingleton<IHostedService, ConsumeScopedServiceHostedService>();
services.AddScoped<IScopedProcessingService, ScopedProcessingService>();

```

## Queued background tasks

A background task queue is based on the .NET 4.x `QueueBackgroundWorkItem` (tentatively scheduled to be built-

in for ASP.NET Core 3.0):

```
public interface IBackgroundTaskQueue
{
    void QueueBackgroundWorkItem(Func< CancellationToken, Task> workItem);

    Task<Func< CancellationToken, Task>> DequeueAsync(
        CancellationToken cancellationToken);
}

public class BackgroundTaskQueue : IBackgroundTaskQueue
{
    private ConcurrentQueue<Func< CancellationToken, Task>> _workItems =
        new ConcurrentQueue<Func< CancellationToken, Task>>();
    private SemaphoreSlim _signal = new SemaphoreSlim(0);

    public void QueueBackgroundWorkItem(
        Func< CancellationToken, Task> workItem)
    {
        if (workItem == null)
        {
            throw new ArgumentNullException(nameof(workItem));
        }

        _workItems.Enqueue(workItem);
        _signal.Release();
    }

    public async Task<Func< CancellationToken, Task>> DequeueAsync(
        CancellationToken cancellationToken)
    {
        await _signal.WaitAsync(cancellationToken);
        _workItems.TryDequeue(out var workItem);

        return workItem;
    }
}
```

In `QueueHostedService`, background tasks (`workItem`) in the queue are dequeued and executed:

```

public class QueuedHostedService : IHostedService
{
    private CancellationTokenSource _shutdown =
        new CancellationTokenSource();
    private Task _backgroundTask;
    private readonly ILogger _logger;

    public QueuedHostedService(IBackgroundTaskQueue taskQueue,
        ILoggerFactory loggerFactory)
    {
        TaskQueue = taskQueue;
        _logger = loggerFactory.CreateLogger<QueuedHostedService>();
    }

    public IBackgroundTaskQueue TaskQueue { get; }

    public Task StartAsync(CancellationToken cancellationToken)
    {
        _logger.LogInformation("Queued Hosted Service is starting.");
        _backgroundTask = Task.Run(BackgroundProceessing);

        return Task.CompletedTask;
    }

    private async Task BackgroundProceessing()
    {
        while (!_shutdown.IsCancellationRequested)
        {
            var workItem =
                await TaskQueue.DequeueAsync(_shutdown.Token);

            try
            {
                await workItem(_shutdown.Token);
            }
            catch (Exception ex)
            {
                _logger.LogError(ex,
                    $"Error occurred executing {nameof(workItem)}.");
            }
        }
    }

    public Task StopAsync(CancellationToken cancellationToken)
    {
        _logger.LogInformation("Queued Hosted Service is stopping.");

        _shutdown.Cancel();

        return Task.WhenAny(_backgroundTask,
            Task.Delay(Timeout.Infinite, cancellationToken));
    }
}

```

The services are registered in `Startup.ConfigureServices`. The `IHostedService` implementation is registered with the `AddHostedService` extension method:

```

services.AddHostedService<QueuedHostedService>();
services.AddSingleton<IBackgroundTaskQueue, BackgroundTaskQueue>();

```

The services are registered in `Startup.ConfigureServices`:

```
services.AddSingleton<IHostedService, QueuedHostedService>();
services.AddSingleton<IBackgroundTaskQueue, BackgroundTaskQueue>();
```

In the Index page model class, the `IBackgroundTaskQueue` is injected into the constructor and assigned to `Queue`:

```
public IndexModel(IBackgroundTaskQueue queue,
    IApplicationLifetime appLifetime,
    ILogger<IndexModel> logger)
{
    Queue = queue;
    _appLifetime = appLifetime;
    _logger = logger;
}

public IBackgroundTaskQueue Queue { get; }
```

When the **Add Task** button is selected on the Index page, the `OnPostAddTask` method is executed.

`QueueBackgroundWorkItem` is called to enqueue the work item:

```
public IActionResult OnPostAddTask()
{
    Queue.QueueBackgroundWorkItem(async token =>
    {
        var guid = Guid.NewGuid().ToString();

        for (int delayLoop = 0; delayLoop < 3; delayLoop++)
        {
            _logger.LogInformation(
                $"Queued Background Task {guid} is running. {delayLoop}/3");
            await Task.Delay(TimeSpan.FromSeconds(5), token);
        }

        _logger.LogInformation(
            $"Queued Background Task {guid} is complete. 3/3");
    });

    return RedirectToPage();
}
```

# Session and app state in ASP.NET Core

6/21/2018 • 17 minutes to read • [Edit Online](#)

By [Rick Anderson](#), [Steve Smith](#), [Diana LaRose](#), and [Luke Latham](#)

HTTP is a stateless protocol. Without taking additional steps, HTTP requests are independent messages that don't retain user values or app state. This article describes several approaches to preserve user data and app state between requests.

[View or download sample code \(how to download\)](#)

## State management

State can be stored using several approaches. Each approach is described later in this topic.

STORAGE APPROACH	STORAGE MECHANISM
<a href="#">Cookies</a>	HTTP cookies (may include data stored using server-side app code)
<a href="#">Session state</a>	HTTP cookies and server-side app code
<a href="#">TempData</a>	HTTP cookies or session state
<a href="#">Query strings</a>	HTTP query strings
<a href="#">Hidden fields</a>	HTTP form fields
<a href="#">HttpContext.Items</a>	Server-side app code
<a href="#">Cache</a>	Server-side app code
<a href="#">Dependency Injection</a>	Server-side app code

## Cookies

Cookies store data across requests. Because cookies are sent with every request, their size should be kept to a minimum. Ideally, only an identifier should be stored in a cookie with the data stored by the app. Most browsers restrict cookie size to 4096 bytes. Only a limited number of cookies are available for each domain.

Because cookies are subject to tampering, they must be validated by the app. Cookies can be deleted by users and expire on clients. However, cookies are generally the most durable form of data persistence on the client.

Cookies are often used for personalization, where content is customized for a known user. The user is only identified and not authenticated in most cases. The cookie can store the user's name, account name, or unique user ID (such as a GUID). You can then use the cookie to access the user's personalized settings, such as their preferred website background color.

Be mindful of the [European Union General Data Protection Regulations \(GDPR\)](#) when issuing cookies and dealing with privacy concerns. For more information, see [General Data Protection Regulation \(GDPR\) support in ASP.NET Core](#).

# Session state

Session state is an ASP.NET Core scenario for storage of user data while the user browses a web app. Session state uses a store maintained by the app to persist data across requests from a client. The session data is backed by a cache and considered ephemeral data—the site should continue to function without the session data.

## NOTE

Session isn't supported in [SignalR](#) apps because a [SignalR Hub](#) may execute independent of an HTTP context. For example, this can occur when a long polling request is held open by a hub beyond the lifetime of the request's HTTP context.

ASP.NET Core maintains session state by providing a cookie to the client that contains a session ID, which is sent to the app with each request. The app uses the session ID to fetch the session data.

Session state exhibits the following behaviors:

- Because the session cookie is specific to the browser, sessions aren't shared across browsers.
- Session cookies are deleted when the browser session ends.
- If a cookie is received for an expired session, a new session is created that uses the same session cookie.
- Empty sessions aren't retained—the session must have at least one value set into it to persist the session across requests. When a session isn't retained, a new session ID is generated for each new request.
- The app retains a session for a limited time after the last request. The app either sets the session timeout or uses the default value of 20 minutes. Session state is ideal for storing user data that's specific to a particular session but where the data doesn't require permanent storage across sessions.
- Session data is deleted either when the [ISession.Clear](#) implementation is called or when the session expires.
- There's no default mechanism to inform app code that a client browser has been closed or when the session cookie is deleted or expired on the client.

## WARNING

Don't store sensitive data in session state. The user might not close the browser and clear the session cookie. Some browsers maintain valid session cookies across browser windows. A session might not be restricted to a single user—the next user might continue to browse the app with the same session cookie.

The in-memory cache provider stores session data in the memory of the server where the app resides. In a server farm scenario:

- Use *sticky sessions* to tie each session to a specific app instance on an individual server. [Azure App Service](#) uses [Application Request Routing \(ARR\)](#) to enforce sticky sessions by default. However, sticky sessions can affect scalability and complicate web app updates. A better approach is to use a Redis or SQL Server distributed cache, which doesn't require sticky sessions. For more information, see [Work with a distributed cache](#).
- The session cookie is encrypted via [IDataProtector](#). Data Protection must be properly configured to read session cookies on each machine. For more information, see [Data Protection in ASP.NET Core](#) and [Key storage providers](#).

## Configure session state

The [Microsoft.AspNetCore.Session](#) package, which is included in the [Microsoft.AspNetCore.App metapackage](#), provides middleware for managing session state. To enable the session middleware, `Startup` must contain:

The [Microsoft.AspNetCore.Session](#) package provides middleware for managing session state. To enable the session middleware, `Startup` must contain:

- Any of the [IDistributedCache](#) memory caches. The `IDistributedCache` implementation is used as a backing

store for session. For more information, see [Work with a distributed cache](#).

- A call to [AddSession](#) in `ConfigureServices`.
- A call to [UseSession](#) in `Configure`.

The following code shows how to set up the in-memory session provider with a default in-memory implementation of `IDistributedCache`:

```
public class Startup
{
    public void ConfigureServices(IServiceCollection services)
    {
        services.Configure<CookiePolicyOptions>(options =>
        {
            options.CheckConsentNeeded = context => true;
            options.MinimumSameSitePolicy = SameSiteMode.None;
        });

        services.AddDistributedMemoryCache();

        services.AddSession(options =>
        {
            // Set a short timeout for easy testing.
            options.IdleTimeout = TimeSpan.FromSeconds(10);
            options.Cookie.HttpOnly = true;
        });

        services.AddMvc()
            .SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
    }

    public void Configure(IApplicationBuilder app, IHostingEnvironment env)
    {
        if (env.IsDevelopment())
        {
            app.UseDeveloperExceptionPage();
        }
        else
        {
            app.UseExceptionHandler("/Error");
            app.UseHsts();
        }

        app.UseHttpsRedirection();
        app.UseStaticFiles();
        app.UseCookiePolicy();
        app.UseSession();
        app.UseHttpContextItemsMiddleware();
        app.UseMvc();
    }
}
```

```

public class Startup
{
    public void ConfigureServices(IServiceCollection services)
    {
        services.AddDistributedMemoryCache();

        services.AddSession(options =>
        {
            // Set a short timeout for easy testing.
            options.IdleTimeout = TimeSpan.FromSeconds(10);
            options.CookieHttpOnly = true;
        });
    }

    services.AddMvc();
}

public void Configure(IApplicationBuilder app)
{
    app.UseSession();
    app.UseHttpContextItemsMiddleware();
    app.UseMvc(routes =>
    {
        routes.MapRoute(
            name: "default",
            template: "{controller=Home}/{action=Index}/{id?}");
    });
}
}

```

The order of middleware is important. In the preceding example, an `InvalidOperationException` exception occurs when `UseSession` is invoked after `UseMvc`. For more information, see [Middleware Ordering](#).

`HttpContext.Session` is available after session state is configured.

`HttpContext.Session` can't be accessed before `UseSession` has been called.

A new session with a new session cookie can't be created after the app has begun writing to the response stream. The exception is recorded in the web server log and not displayed in the browser.

### Load session state asynchronously

The default session provider in ASP.NET Core loads session records from the underlying `IDistributedCache` backing store asynchronously only if the `ISession.LoadAsync` method is explicitly called before the `TryGetValue`, `Set`, or `Remove` methods. If `LoadAsync` isn't called first, the underlying session record is loaded synchronously, which can incur a performance penalty at scale.

To have apps enforce this pattern, wrap the `DistributedSessionStore` and `DistributedSession` implementations with versions that throw an exception if the `LoadAsync` method isn't called before `TryGetValue`, `Set`, or `Remove`. Register the wrapped versions in the services container.

### Session options

To override session defaults, use `SessionOptions`.

OPTION	DESCRIPTION
<code>Cookie</code>	Determines the settings used to create the cookie. <code>Name</code> defaults to <code>SessionDefaults.CookieName</code> ( <code>.AspNetCore.Session</code> ). <code>Path</code> defaults to <code>SessionDefaults.CookiePath</code> ( <code>/</code> ). <code>SameSite</code> defaults to <code>SameSiteMode.Lax</code> ( <code>1</code> ). <code>HttpOnly</code> defaults to <code>true</code> . <code>IsEssential</code> defaults to <code>false</code> .

OPTION	DESCRIPTION
IdleTimeout	The <code>IdleTimeout</code> indicates how long the session can be idle before its contents are abandoned. Each session access resets the timeout. Note this only applies to the content of the session, not the cookie. The default is 20 minutes.
IOTimeout	The maximum amount of time allowed to load a session from the store or to commit it back to the store. Note this may only apply to asynchronous operations. This timeout can be disabled using <code>InfiniteTimeSpan</code> . The default is 1 minute.

Session uses a cookie to track and identify requests from a single browser. By default, this cookie is named `.AspNetCore.Session`, and it uses a path of `/`. Because the cookie default doesn't specify a domain, it isn't made available to the client-side script on the page (because `HttpOnly` defaults to `true`).

OPTION	DESCRIPTION
CookieDomain	Determines the domain used to create the cookie. <code>CookieDomain</code> isn't set by default.
CookieHttpOnly	Determines if the browser should allow the cookie to be accessed by client-side JavaScript. The default is <code>true</code> , which means the cookie is only passed to HTTP requests and isn't made available to script on the page.
CookieName	Determines the cookie name used to persist the session ID. The default is <code>SessionDefaults.CookieName</code> ( <code>.AspNetCore.Session</code> ).
CookiePath	Determines the path used to create the cookie. Defaults to <code>SessionDefaults.CookiePath</code> ( <code>/</code> ).
CookieSecure	Determines if the cookie should only be transmitted on HTTPS requests. The default is <code>CookieSecurePolicy.None</code> (2).
IdleTimeout	The <code>IdleTimeout</code> indicates how long the session can be idle before its contents are abandoned. Each session access resets the timeout. Note this only applies to the content of the session, not the cookie. The default is 20 minutes.

Session uses a cookie to track and identify requests from a single browser. By default, this cookie is named `.AspNet.Session`, and it uses a path of `/`.

To override cookie session defaults, use `SessionOptions`:

```

public void ConfigureServices(IServiceCollection services)
{
    services.Configure<CookiePolicyOptions>(options =>
    {
        options.CheckConsentNeeded = context => true;
        options.MinimumSameSitePolicy = SameSiteMode.None;
    });

    services.AddDistributedMemoryCache();

    services.AddMvc()
        .SetCompatibilityVersion(CompatibilityVersion.Version_2_1);

    services.AddSession(options =>
    {
        options.Cookie.Name = ".AdventureWorks.Session";
        options.IdleTimeout = TimeSpan.FromSeconds(10);
    });
}

```

```

public void ConfigureServices(IServiceCollection services)
{
    services.AddDistributedMemoryCache();

    services.AddSession(options =>
    {
        options.CookieName = ".AdventureWorks.Session";
        options.IdleTimeout = TimeSpan.FromSeconds(10);
    });

    services.AddMvc();
}

```

The app uses the [IdleTimeout](#) property to determine how long a session can be idle before its contents in the server's cache are abandoned. This property is independent of the cookie expiration. Each request that passes through the [Session Middleware](#) resets the timeout.

Session state is *non-locking*. If two requests simultaneously attempt to modify the contents of a session, the last request overrides the first. `Session` is implemented as a *coherent session*, which means that all the contents are stored together. When two requests seek to modify different session values, the last request may override session changes made by the first.

## Set and get Session values

Session state is accessed from a Razor Pages [PageModel](#) class or MVC [Controller](#) class with [HttpContext.Session](#). This property is an [ISession](#) implementation.

The `ISession` implementation provides several extension methods to set and retrieve integer and string values.

The extension methods are in the [Microsoft.AspNetCore.Http](#) namespace (add a

`using Microsoft.AspNetCore.Http;` statement to gain access to the extension methods) when the

[Microsoft.AspNetCore.Http.Extensions](#) package is referenced by the project. Both packages are included in the [Microsoft.AspNetCore.App](#) metapackage.

The `ISession` implementation provides several extension methods to set and retrieve integer and string values.

The extension methods are in the [Microsoft.AspNetCore.Http](#) namespace (add a

`using Microsoft.AspNetCore.Http;` statement to gain access to the extension methods) when the

[Microsoft.AspNetCore.Http.Extensions](#) package is referenced by the project.

`ISession` extension methods:

- [Get\(I Session, String\)](#)
- [GetInt32\(I Session, String\)](#)
- [GetString\(I Session, String\)](#)
- [SetInt32\(I Session, String, Int32\)](#)
- [SetString\(I Session, String, String\)](#)

The following example retrieves the session value for the `IndexModel.SessionKeyName` key (`_Name` in the sample app) in a Razor Pages page:

```
@page
@using Microsoft.AspNetCore.Http
@model IndexModel

...
Name: @HttpContext.Session.GetString(IndexModel.SessionKeyName)
```

The following example shows how to set and get an integer and a string:

```
public class IndexModel : PageModel
{
    public const string SessionKeyName = "_Name";
    public const string SessionKeyAge = "_Age";
    const string SessionKeyTime = "_Time";

    public string SessionInfo_Name { get; private set; }
    public string SessionInfo_Age { get; private set; }
    public string SessionInfo_CurrentTime { get; private set; }
    public string SessionInfo_SessionTime { get; private set; }
    public string SessionInfo_MiddlewareValue { get; private set; }

    public void OnGet()
    {
        // Requires: using Microsoft.AspNetCore.Http;
        if (string.IsNullOrEmpty(HttpContext.Session.GetString(SessionKeyName)))
        {
            HttpContext.Session.SetString(SessionKeyName, "The Doctor");
            HttpContext.Session.SetInt32(SessionKeyAge, 773);
        }
    }

    var name = HttpContext.Session.GetString(SessionKeyName);
    var age = HttpContext.Session.GetInt32(SessionKeyAge);
```

```

public class HomeController : Controller
{
    const string SessionKeyName = "_Name";
    const string SessionKeyYearsMember = "_YearsMember";
    const string SessionKeyDate = "_Date";

    public IActionResult Index()
    {
        // Requires using Microsoft.AspNetCore.Http;
        HttpContext.Session.SetString(SessionKeyName, "Rick");
        HttpContext.Session.SetInt32(SessionKeyYearsMember, 3);

        return RedirectToAction("SessionNameYears");
    }

    public IActionResult SessionNameYears()
    {
        var name = HttpContext.Session.GetString(SessionKeyName);
        var yearsMember = HttpContext.Session.GetInt32(SessionKeyYearsMember);

        return Content($"Name: \"{name}\", Membership years: \"{yearsMember}\"");
    }
}

```

All session data must be serialized to enable a distributed cache scenario, even when using the in-memory cache. Minimal string and number serializers are provided (see the methods and extension methods of [ISession](#)). Complex types must be serialized by the user using another mechanism, such as JSON.

Add the following extension methods to set and get serializable objects:

```

public static class SessionExtensions
{
    public static void Set<T>(this ISession session, string key, T value)
    {
        session.SetString(key, JsonConvert.SerializeObject(value));
    }

    public static T Get<T>(this ISession session, string key)
    {
        var value = session.GetString(key);

        return value == null ? default(T) :
            JsonConvert.DeserializeObject<T>(value);
    }
}

```

```

public static class SessionExtensions
{
    public static void Set<T>(this ISession session, string key, T value)
    {
        session.SetString(key, JsonConvert.SerializeObject(value));
    }

    public static T Get<T>(this ISession session, string key)
    {
        var value = session.GetString(key);
        return value == null ? default(T) :
            JsonConvert.DeserializeObject<T>(value);
    }
}

```

The following example shows how to set and get a serializable object with the extension methods:

```
// Requires you add the Set and Get extension method mentioned in the topic.  
if (HttpContext.Session.Get<DateTime>(SessionKeyTime) == default(DateTime))  
{  
    HttpContext.Session.Set<DateTime>(SessionKeyTime, currentTime);  
}
```

```
public IActionResult SetDate()  
{  
    // Requires you add the Set extension method mentioned in the topic.  
    HttpContext.Session.Set<DateTime>(SessionKeyDate, DateTime.Now);  
  
    return RedirectToAction("GetDate");  
}  
  
public IActionResult GetDate()  
{  
    // Requires you add the Get extension method mentioned in the topic.  
    var date = HttpContext.Session.Get<DateTime>(SessionKeyDate);  
    var sessionTime = date.TimeOfDay.ToString();  
    var currentTime = DateTime.Now.TimeOfDay.ToString();  
  
    return Content($"Current time: {currentTime} - "  
        + $"session time: {sessionTime}");  
}
```

## TempData

ASP.NET Core exposes the [TempData property of a Razor Pages page model](#) or [TempData of an MVC controller](#). This property stores data until it's read. The [Keep](#) and [Peek](#) methods can be used to examine the data without deletion. TempData is particularly useful for redirection when data is required for more than a single request. TempData is implemented by TempData providers using either cookies or session state.

### TempData providers

In ASP.NET Core 2.0 or later, the cookie-based TempData provider is used by default to store TempData in cookies.

The cookie data is encrypted using [IDataProtector](#), encoded with [Base64UrlTextEncoder](#), then chunked. Because the cookie is chunked, the single cookie size limit found in ASP.NET Core 1.x doesn't apply. The cookie data isn't compressed because compressing encrypted data can lead to security problems such as the [CRIME](#) and [BREACH](#) attacks. For more information on the cookie-based TempData provider, see [CookieTempDataProvider](#).

In ASP.NET Core 1.0 and 1.1, the session state TempData provider is the default provider.

### Choose a TempData provider

Choosing a TempData provider involves several considerations, such as:

1. Does the app already use session state? If so, using the session state TempData provider has no additional cost to the app (aside from the size of the data).
2. Does the app use TempData only sparingly for relatively small amounts of data (up to 500 bytes)? If so, the cookie TempData provider adds a small cost to each request that carries TempData. If not, the session state TempData provider can be beneficial to avoid round-tripping a large amount of data in each request until the TempData is consumed.
3. Does the app run in a server farm on multiple servers? If so, there's no additional configuration required to use the cookie TempData provider outside of Data Protection (see [Data Protection](#) and [Key storage providers](#)).

#### NOTE

Most web clients (such as web browsers) enforce limits on the maximum size of each cookie, the total number of cookies, or both. When using the cookie TempData provider, verify the app won't exceed these limits. Consider the total size of the data. Account for increases in cookie size due to encryption and chunking.

## Configure the TempData provider

The cookie-based TempData provider is enabled by default.

To enable the session-based TempData provider, use the [AddSessionStateTempDataProvider](#) extension method:

```
public void ConfigureServices(IServiceCollection services)
{
    services.Configure<CookiePolicyOptions>(options =>
    {
        options.CheckConsentNeeded = context => true;
        options.MinimumSameSitePolicy = SameSiteMode.None;
    });

    services.AddMvc()
        .SetCompatibilityVersion(CompatibilityVersion.Version_2_1)
        .AddSessionStateTempDataProvider();

    services.AddSession();
}

public void Configure(IApplicationBuilder app, IHostingEnvironment env)
{
    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
        app.UseDatabaseErrorPage();
    }
    else
    {
        app.UseExceptionHandler("/Error");
        app.UseHsts();
    }

    app.UseHttpsRedirection();
    app.UseStaticFiles();
    app.UseCookiePolicy();
    app.UseSession();
    app.UseMvc();
}
```

The following `Startup` class code configures the session-based TempData provider:

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddMvc();
    services.AddSession();
}

public void Configure(IApplicationBuilder app, IHostingEnvironment env, ILoggerFactory loggerFactory)
{
    app.UseSession();
    app.UseMvc(routes =>
    {
        routes.MapRoute(
            name: "default",
            template: "{controller=Home}/{action=Index}/{id?}");
    });
}
```

The order of middleware is important. In the preceding example, an `InvalidOperationException` exception occurs when `UseSession` is invoked after `UseMvc`. For more information, see [Middleware Ordering](#).

#### IMPORTANT

If targeting .NET Framework and using the session-based `TempData` provider, add the [Microsoft.AspNetCore.Session](#) package to the project.

## Query strings

A limited amount of data can be passed from one request to another by adding it to the new request's query string. This is useful for capturing state in a persistent manner that allows links with embedded state to be shared through email or social networks. Because URL query strings are public, never use query strings for sensitive data.

In addition to unintended sharing, including data in query strings can create opportunities for [Cross-Site Request Forgery \(CSRF\)](#) attacks, which can trick users into visiting malicious sites while authenticated. Attackers can then steal user data from the app or take malicious actions on behalf of the user. Any preserved app or session state must protect against CSRF attacks. For more information, see [Prevent Cross-Site Request Forgery \(XSRF/CSRF\) attacks](#).

## Hidden fields

Data can be saved in hidden form fields and posted back on the next request. This is common in multi-page forms. Because the client can potentially tamper with the data, the app must always revalidate the data stored in hidden fields.

## HttpContext.Items

The `HttpContext.Items` collection is used to store data while processing a single request. The collection's contents are discarded after a request is processed. The `Items` collection is often used to allow components or middleware to communicate when they operate at different points in time during a request and have no direct way to pass parameters.

In the following example, `middleware` adds `isVerified` to the `Items` collection.

```
app.Use(async (context, next) =>
{
    // perform some verification
    context.Items["isVerified"] = true;
    await next.Invoke();
});
```

Later in the pipeline, another middleware can access the value of `isVerified`:

```
app.Run(async (context) =>
{
    await context.Response.WriteAsync($"Verified: {context.Items["isVerified"]}");
});
```

For middleware that's only used by a single app, `string` keys are acceptable. Middleware shared between app instances should use unique object keys to avoid key collisions. The following example shows how to use a unique object key defined in a middleware class:

```
public class HttpContextItemsMiddleware
{
    private readonly RequestDelegate _next;
    public static readonly object HttpContextItemsMiddlewareKey = new Object();

    public HttpContextItemsMiddleware(RequestDelegate next)
    {
        _next = next;
    }

    public async Task Invoke(HttpContext httpContext)
    {
        httpContext.Items[HttpContextItemsMiddlewareKey] = "K-9";

        await _next(httpContext);
    }
}

public static class HttpContextItemsMiddlewareExtensions
{
    public static IApplicationBuilder
        UseHttpContextItemsMiddleware(this IApplicationBuilder builder)
    {
        return builder.UseMiddleware<HttpContextItemsMiddleware>();
    }
}
```

```
// You may need to install the Microsoft.AspNetCore.Http.Abstractions package
public class HttpContextItemsMiddleware
{
    private readonly RequestDelegate _next;
    public static readonly object HttpContextItemsMiddlewareKey = new Object();

    public HttpContextItemsMiddleware(RequestDelegate next)
    {
        _next = next;
    }

    public async Task Invoke(HttpContext httpContext)
    {
        httpContext.Items[HttpContextItemsMiddlewareKey] = "K-9";

        await _next(httpContext);
    }
}

public static class HttpContextItemsMiddlewareExtensions
{
    public static IApplicationBuilder
        UseHttpContextItemsMiddleware(this IApplicationBuilder builder)
    {
        return builder.UseMiddleware<HttpContextItemsMiddleware>();
    }
}
```

Other code can access the value stored in `HttpContext.Items` using the key exposed by the middleware class:

```
HttpContext.Items
    .TryGetValue(HttpContextItemsMiddleware.HttpContextItemsMiddlewareKey,
        out var middlewareSetValue);
SessionInfo_MiddlewareValue =
    middlewareSetValue?.ToString() ?? "Middleware value not set!";
```

```
public IActionResult GetMiddlewareValue()
{
    var middlewareSetValue =
        HttpContext.Items[HttpContextItemsMiddleware.HttpContextItemsMiddlewareKey];

    return Content($"Value: {middlewareSetValue}");
}
```

This approach also has the advantage of eliminating the use of key strings in the code.

## Cache

Caching is an efficient way to store and retrieve data. The app can control the lifetime of cached items.

Cached data isn't associated with a specific request, user, or session. **Be careful not to cache user-specific data that may be retrieved by other users' requests.**

For more information, see the [Cache responses](#) topic.

## Dependency Injection

Use [Dependency Injection](#) to make data available to all users:

1. Define a service containing the data. For example, a class named `MyAppData` is defined:

```
public class MyAppData
{
    // Declare properties and methods
}
```

2. Add the service class to `Startup.ConfigureServices`:

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddSingleton<MyAppData>();
}
```

3. Consume the data service class:

```
public class IndexModel : PageModel
{
    public IndexModel(MyAppData myService)
    {
        // Do something with the service
        // Examples: Read data, store in a field or property
    }
}
```

```
public class HomeController : Controller
{
    public HomeController(MyAppData myService)
    {
        // Do something with the service
        // Examples: Read data, store in a field or property
    }
}
```

## Common errors

- "Unable to resolve service for type 'Microsoft.Extensions.Caching.Distributed.IDistributedCache' while attempting to activate 'Microsoft.AspNetCore.Session.DistributedSessionStore'."

This is usually caused by failing to configure at least one `IDistributedCache` implementation. For more information, see [Work with a distributed cache](#) and [Cache in-memory](#).

- In the event that the session middleware fails to persist a session (for example, if the backing store isn't available), the middleware logs the exception and the request continues normally. This leads to unpredictable behavior.

For example, a user stores a shopping cart in session. The user adds an item to the cart but the commit fails. The app doesn't know about the failure so it reports to the user that the item was added to their cart, which isn't true.

The recommended approach to check for errors is to call `await feature.Session.CommitAsync();` from app code when the app is done writing to the session. `CommitAsync` throws an exception if the backing store is unavailable. If `CommitAsync` fails, the app can process the exception. `LoadAsync` throws under the same conditions where the data store is unavailable.

# Web server implementations in ASP.NET Core

6/21/2018 • 4 minutes to read • [Edit Online](#)

By [Tom Dykstra](#), [Steve Smith](#), [Stephen Halter](#), and [Chris Ross](#)

An ASP.NET Core app runs with an in-process HTTP server implementation. The server implementation listens for HTTP requests and surfaces them to the app as sets of [request features](#) composed into an [HttpContext](#).

ASP.NET Core ships two server implementations:

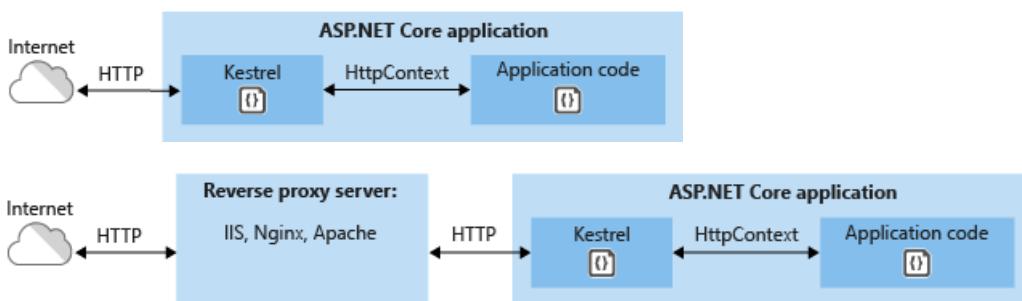

- [Kestrel](#) is the default, cross-platform HTTP server for ASP.NET Core.
- [HTTP.sys](#) is a Windows-only HTTP server based on the [HTTP.sys kernel driver](#) and [HTTP Server API](#).  
(HTTP.sys is called [WebListener](#) in ASP.NET Core 1.x.)

## Kestrel

Kestrel is the default web server included in ASP.NET Core project templates.

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

Kestrel can be used by itself or with a *reverse proxy server*, such as IIS, Nginx, or Apache. A reverse proxy server receives HTTP requests from the Internet and forwards them to Kestrel after some preliminary handling.

Either configuration—with or without a reverse proxy server—is a valid and supported hosting configuration for ASP.NET Core 2.0 or later apps. For more information, see [When to use Kestrel with a reverse proxy](#).

IIS, Nginx, and Apache can't be used without Kestrel or a [custom server implementation](#). ASP.NET Core was designed to run in its own process so that it can behave consistently across platforms. IIS, Nginx, and Apache dictate their own startup procedure and environment. To use these server technologies directly, ASP.NET Core would need to adapt to the requirements of each server. Using a web server implementation, such as Kestrel, ASP.NET Core has control over the startup process and environment when hosted on different server technologies.

### IIS with Kestrel

When using [IIS](#) or [IIS Express](#) as a reverse proxy for ASP.NET Core, the ASP.NET Core app runs in a process separate from the IIS worker process. In the IIS process, the [ASP.NET Core Module](#) coordinates the reverse proxy relationship. The primary functions of the ASP.NET Core Module are to start the ASP.NET Core app, restart the app when it crashes, and forward HTTP traffic to the app. For more information, see [ASP.NET Core Module](#).

### Nginx with Kestrel

For information on how to use Nginx on Linux as a reverse proxy server for Kestrel, see [Host on Linux with Nginx](#).

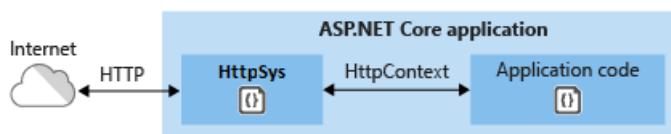

## Apache with Kestrel

For information on how to use Apache on Linux as a reverse proxy server for Kestrel, see [Host on Linux with Apache](#).

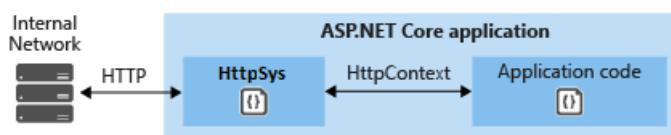

## HTTP.sys

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

If ASP.NET Core apps are run on Windows, HTTP.sys is an alternative to Kestrel. Kestrel is generally recommended for best performance. HTTP.sys can be used in scenarios where the app is exposed to the Internet and required features are supported by HTTP.sys but not Kestrel. For information on HTTP.sys features, see [HTTP.sys](#).

HTTP.sys can also be used for apps that are only exposed to an internal network.

## ASP.NET Core server infrastructure

The [IApplicationBuilder](#) available in the `Startup.Configure` method exposes the [ServerFeatures](#) property of type [IFeatureCollection](#). Kestrel and HTTP.sys (WebListener in ASP.NET Core 1.x) only expose a single feature each, [IServerAddressesFeature](#), but different server implementations may expose additional functionality.

[IServerAddressesFeature](#) can be used to find out which port the server implementation has bound at runtime.

## Custom servers

If the built-in servers don't meet the app's requirements, a custom server implementation can be created. The [Open Web Interface for .NET \(OWIN\) guide](#) demonstrates how to write a [Nowin](#)-based [IServer](#) implementation. Only the feature interfaces that the app uses require implementation, though at a minimum [IHttpRequestFeature](#) and [IHttpResponseFeature](#) must be supported.

## Server startup

When using [Visual Studio](#), [Visual Studio for Mac](#), or [Visual Studio Code](#), the server is launched when the app is started by the Integrated Development Environment (IDE). In Visual Studio on Windows, launch profiles can be used to start the app and server with either [IIS Express/ASP.NET Core Module](#) or the console. In Visual Studio Code, the app and server are started by [Omnisharp](#), which activates the CoreCLR debugger. Using Visual Studio for Mac, the app and server are started by the [Mono Soft-Mode Debugger](#).

When launching an app from a command prompt in the project's folder, `dotnet run` launches the app and server (Kestrel and HTTP.sys only). The configuration is specified by the `-c|--configuration` option, which is set to either `Debug` (default) or `Release`. If launch profiles are present in a `launchSettings.json` file, use the `--launch-profile <NAME>` option to set the launch profile (for example, `Development` or `Production`). For more information, see the [dotnet run](#) and [.NET Core distribution packaging](#) topics.

## Additional resources

- [Kestrel](#)
- [Kestrel with IIS](#)
- [Host on Linux with Nginx](#)
- [Host on Linux with Apache](#)
- [HTTP.sys](#) (for ASP.NET Core 1.x, see [WebListener](#))

# Kestrel web server implementation in ASP.NET Core

6/21/2018 • 22 minutes to read • [Edit Online](#)

By Tom Dykstra, Chris Ross, and Stephen Halter

Kestrel is a cross-platform [web server for ASP.NET Core](#). Kestrel is the web server that's included by default in ASP.NET Core project templates.

Kestrel supports the following features:

- HTTPS
- Opaque upgrade used to enable [WebSockets](#)
- Unix sockets for high performance behind Nginx

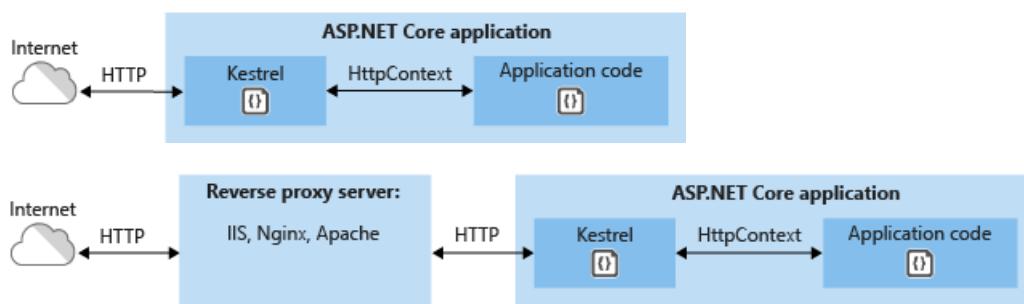

Kestrel is supported on all platforms and versions that .NET Core supports.

[View or download sample code \(how to download\)](#)

## When to use Kestrel with a reverse proxy

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

You can use Kestrel by itself or with a *reverse proxy server*, such as IIS, Nginx, or Apache. A reverse proxy server receives HTTP requests from the Internet and forwards them to Kestrel after some preliminary handling.

Either configuration—with or without a reverse proxy server—is a valid and supported hosting configuration for ASP.NET Core 2.0 or later apps.

A reverse proxy scenario exists when there are multiple apps that share the same IP and port running on a single server. Kestrel doesn't support this scenario because Kestrel doesn't support sharing the same IP and port among multiple processes. When Kestrel is configured to listen on a port, Kestrel handles all of the traffic for that port regardless of requests' host header. A reverse proxy that can share ports has the ability to forward requests to Kestrel on a unique IP and port.

Even if a reverse proxy server isn't required, using a reverse proxy server might be a good choice:

- It can limit the exposed public surface area of the apps that it hosts.
- It provides an additional layer of configuration and defense.
- It might integrate better with existing infrastructure.
- It simplifies load balancing and SSL configuration. Only the reverse proxy server requires an SSL certificate, and that server can communicate with your app servers on the internal network using plain HTTP.

## WARNING

If not using a reverse proxy with host filtering enabled, [host filtering](#) must be enabled.

# How to use Kestrel in ASP.NET Core apps

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

The [Microsoft.AspNetCore.Server.Kestrel](#) package is included in the [Microsoft.AspNetCore.App metapackage] (xref:fundamentals/metapackage-app) (ASP.NET Core 2.1 or later).

ASP.NET Core project templates use Kestrel by default. In *Program.cs*, the template code calls [CreateDefaultBuilder](#), which calls [UseKestrel](#) behind the scenes.

```
public static void Main(string[] args)
{
    CreateWebHostBuilder(args).Build().Run();
}

public static IWebHostBuilder CreateWebHostBuilder(string[] args) =>
    WebHost.CreateDefaultBuilder(args)
        .UseStartup<Startup>();
```

## Kestrel options

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

The Kestrel web server has constraint configuration options that are especially useful in Internet-facing deployments. A few important limits that can be customized:

- Maximum client connections
- Maximum request body size
- Minimum request body data rate

Set these and other constraints on the [Limits](#) property of the [KestrelServerOptions](#) class. The `Limits` property holds an instance of the [KestrelServerLimits](#) class.

### Maximum client connections

[MaxConcurrentConnections](#)

[MaxConcurrentUpgradedConnections](#)

The maximum number of concurrent open TCP connections can be set for the entire app with the following code:

```
.UseKestrel(options =>
{
    options.Limits.MaxConcurrentConnections = 100;
    options.Limits.MaxConcurrentUpgradedConnections = 100;
    options.Limits.MaxRequestBodySize = 10 * 1024;
    options.Limits.MinRequestBodyDataRate =
        new MinDataRate(bytesPerSecond: 100, gracePeriod: TimeSpan.FromSeconds(10));
    options.Limits.MinResponseDataRate =
        new MinDataRate(bytesPerSecond: 100, gracePeriod: TimeSpan.FromSeconds(10));
    options.Listen(IPAddress.Loopback, 5000);
    options.Listen(IPAddress.Loopback, 5001, listenOptions =>
    {
        listenOptions.UseHttps("testCert.pfx", "testPassword");
    });
});
```

There's a separate limit for connections that have been upgraded from HTTP or HTTPS to another protocol (for example, on a WebSockets request). After a connection is upgraded, it isn't counted against the `MaxConcurrentConnections` limit.

```
.UseKestrel(options =>
{
    options.Limits.MaxConcurrentConnections = 100;
    options.Limits.MaxConcurrentUpgradedConnections = 100;
    options.Limits.MaxRequestBodySize = 10 * 1024;
    options.Limits.MinRequestBodyDataRate =
        new MinDataRate(bytesPerSecond: 100, gracePeriod: TimeSpan.FromSeconds(10));
    options.Limits.MinResponseDataRate =
        new MinDataRate(bytesPerSecond: 100, gracePeriod: TimeSpan.FromSeconds(10));
    options.Listen(IPAddress.Loopback, 5000);
    options.Listen(IPAddress.Loopback, 5001, listenOptions =>
    {
        listenOptions.UseHttps("testCert.pfx", "testPassword");
    });
});
```

The maximum number of connections is unlimited (null) by default.

## Maximum request body size

### MaxRequestBodySize

The default maximum request body size is 30,000,000 bytes, which is approximately 28.6 MB.

The recommended approach to override the limit in an ASP.NET Core MVC app is to use the [RequestSizeLimit](#) attribute on an action method:

```
[RequestSizeLimit(100000000)]
public IActionResult MyActionMethod()
```

Here's an example that shows how to configure the constraint for the app on every request:

```

.UseKestrel(options =>
{
    options.Limits.MaxConcurrentConnections = 100;
    options.Limits.MaxConcurrentUpgradedConnections = 100;
    options.Limits.MaxRequestBodySize = 10 * 1024;
    options.Limits.MinRequestBodyDataRate =
        new MinDataRate(bytesPerSecond: 100, gracePeriod: TimeSpan.FromSeconds(10));
    options.Limits.MinResponseDataRate =
        new MinDataRate(bytesPerSecond: 100, gracePeriod: TimeSpan.FromSeconds(10));
    options.Listen(IPAddress.Loopback, 5000);
    options.Listen(IPAddress.Loopback, 5001, listenOptions =>
    {
        listenOptions.UseHttps("testCert.pfx", "testPassword");
    });
});

```

You can override the setting on a specific request in middleware:

```

app.Run(async (context) =>
{
    context.Features.Get< IHttpMaxRequestBodySizeFeature>()
        .MaxRequestBodySize = 10 * 1024;
    context.Features.Get< IHttpMinRequestBodyDataRateFeature>()
        .MinDataRate = new MinDataRate(bytesPerSecond: 100,
            gracePeriod: TimeSpan.FromSeconds(10));
    context.Features.Get< IHttpMinResponseDataRateFeature>()
        .MinDataRate = new MinDataRate(bytesPerSecond: 100,
            gracePeriod: TimeSpan.FromSeconds(10));
}

```

An exception is thrown if you attempt to configure the limit on a request after the app has started to read the request. There's an `IsReadOnly` property that indicates if the `MaxRequestBodySize` property is in read-only state, meaning it's too late to configure the limit.

## Minimum request body data rate

[MinRequestBodyDataRate](#)

[MinResponseDataRate](#)

Kestrel checks every second if data is arriving at the specified rate in bytes/second. If the rate drops below the minimum, the connection is timed out. The grace period is the amount of time that Kestrel gives the client to increase its send rate up to the minimum; the rate isn't checked during that time. The grace period helps avoid dropping connections that are initially sending data at a slow rate due to TCP slow-start.

The default minimum rate is 240 bytes/second with a 5 second grace period.

A minimum rate also applies to the response. The code to set the request limit and the response limit is the same except for having `RequestBody` or `Response` in the property and interface names.

Here's an example that shows how to configure the minimum data rates in *Program.cs*:

```

.UseKestrel(options =>
{
    options.Limits.MaxConcurrentConnections = 100;
    options.Limits.MaxConcurrentUpgradedConnections = 100;
    options.Limits.MaxRequestBodySize = 10 * 1024;
    options.Limits.MinRequestBodyDataRate =
        new MinDataRate(bytesPerSecond: 100, gracePeriod: TimeSpan.FromSeconds(10));
    options.Limits.MinResponseDataRate =
        new MinDataRate(bytesPerSecond: 100, gracePeriod: TimeSpan.FromSeconds(10));
    options.Listen(IPAddress.Loopback, 5000);
    options.Listen(IPAddress.Loopback, 5001, listenOptions =>
    {
        listenOptions.UseHttps("testCert.pfx", "testPassword");
    });
});

```

You can configure the rates per request in middleware:

```

app.Run(async (context) =>
{
    context.Features.Get< IHttpMaxRequestBodySizeFeature>()
        .MaxRequestBodySize = 10 * 1024;
    context.Features.Get< IHttpMinRequestBodyDataRateFeature>()
        .MinDataRate = new MinDataRate(bytesPerSecond: 100,
            gracePeriod: TimeSpan.FromSeconds(10));
    context.Features.Get< IHttpMinResponseDataRateFeature>()
        .MinDataRate = new MinDataRate(bytesPerSecond: 100,
            gracePeriod: TimeSpan.FromSeconds(10));
}

```

For information about other Kestrel options and limits, see:

- [KestrelServerOptions](#)
- [KestrelServerLimits](#)
- [ListenOptions](#)

## Endpoint configuration

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

By default, ASP.NET Core binds to `http://localhost:5000`. Call [Listen](#) or [ListenUnixSocket](#) methods on [KestrelServerOptions](#) to configure URL prefixes and ports for Kestrel. `useUrls`, the `--urls` command-line argument, `urls` host configuration key, and the `ASPNETCORE_URLS` environment variable also work but have the limitations noted later in this section.

The `urls` host configuration key must come from the host configuration, not the app configuration. Adding a `urls` key and value to `appsettings.json` doesn't affect host configuration because the host is completely initialized by the time the configuration is read from the configuration file. However, a `urls` key in `appsettings.json` can be used with [UseConfiguration](#) on the host builder to configure the host:

```

var config = new ConfigurationBuilder()
    .SetBasePath(Directory.GetCurrentDirectory())
    .AddJsonFile("appSettings.json", optional: true, reloadOnChange: true)
    .Build();

var host = new WebHostBuilder()
    .UseKestrel()
    .UseConfiguration(config)
    .UseContentRoot(Directory.GetCurrentDirectory())
    .UseStartup<Startup>()
    .Build();

```

By default, ASP.NET Core binds to:

- `http://localhost:5000`
- `https://localhost:5001` (when a local development certificate is present)

A development certificate is created:

- When the [.NET Core SDK](#) is installed.
- The [dev-certs tool](#) is used to create a certificate.

Some browsers require that you grant explicit permission to the browser to trust the local development certificate.

ASP.NET Core 2.1 and later project templates configure apps to run on HTTPS by default and include [HTTPS redirection and HSTS support](#).

Call [Listen](#) or [ListenUnixSocket](#) methods on [KestrelServerOptions](#) to configure URL prefixes and ports for Kestrel.

`UseUrls`, the `--urls` command-line argument, `urls` host configuration key, and the `ASPNETCORE_URLS` environment variable also work but have the limitations noted later in this section (a default certificate must be available for HTTPS endpoint configuration).

ASP.NET Core 2.1 `KestrelServerOptions` configuration:

#### **ConfigureEndpointDefaults(Action<ListenOptions>)**

Specifies a configuration `Action` to run for each specified endpoint. Calling `ConfigureEndpointDefaults` multiple times replaces prior `Action`s with the last `Action` specified.

#### **ConfigureHttpsDefaults(Action<HttpsConnectionAdapterOptions>)**

Specifies a configuration `Action` to run for each HTTPS endpoint. Calling `ConfigureHttpsDefaults` multiple times replaces prior `Action`s with the last `Action` specified.

#### **Configure(IConfiguration)**

Creates a configuration loader for setting up Kestrel that takes an [IConfiguration](#) as input. The configuration must be scoped to the configuration section for Kestrel.

#### **ListenOptions.UseHttps**

Configure Kestrel to use HTTPS.

`ListenOptions.UseHttps` extensions:

- `UseHttps` – Configure Kestrel to use HTTPS with the default certificate. Throws an exception if no default certificate is configured.
- `UseHttps(string fileName)`
- `UseHttps(string fileName, string password)`

- `UseHttps(string fileName, string password, Action<HttpsConnectionAdapterOptions> configureOptions)`
- `UseHttps(StoreName storeName, string subject)`
- `UseHttps(StoreName storeName, string subject, bool allowInvalid)`
- `UseHttps(StoreName storeName, string subject, bool allowInvalid, StoreLocation location)`
- `UseHttps(StoreName storeName, string subject, bool allowInvalid, StoreLocation location, Action<HttpsConnectionAdapterOptions> configureOptions)`
- `UseHttps(X509Certificate2 serverCertificate)`
- `UseHttps(X509Certificate2 serverCertificate, Action<HttpsConnectionAdapterOptions> configureOptions)`
- `UseHttps(Action<HttpsConnectionAdapterOptions> configureOptions)`

`ListenOptions.UseHttps` parameters:

- `filename` is the path and file name of a certificate file, relative to the directory that contains the app's content files.
- `password` is the password required to access the X.509 certificate data.
- `configureOptions` is an `Action` to configure the `HttpsConnectionAdapterOptions`. Returns the `ListenOptions`.
- `storeName` is the certificate store from which to load the certificate.
- `subject` is the subject name for the certificate.
- `allowInvalid` indicates if invalid certificates should be considered, such as self-signed certificates.
- `location` is the store location to load the certificate from.
- `serverCertificate` is the X.509 certificate.

In production, HTTPS must be explicitly configured. At a minimum, a default certificate must be provided.

Supported configurations described next:

- No configuration
- Replace the default certificate from configuration
- Change the defaults in code

*No configuration*

Kestrel listens on `http://localhost:5000` and `https://localhost:5001` (if a default cert is available).

Specify URLs using the:

- `ASPNETCORE_URLS` environment variable.
- `--urls` command-line argument.
- `urls` host configuration key.
- `UseUrls` extension method.

For more information, see [Server URLs](#) and [Override configuration](#).

The value provided using these approaches can be one or more HTTP and HTTPS endpoints (HTTPS if a default cert is available). Configure the value as a semicolon-separated list (for example,

```
"Urls": "http://localhost:8000;http://localhost:8001" ).
```

*Replace the default certificate from configuration*

`WebHost.CreateDefaultBuilder` calls `serverOptions.Configure(context.Configuration.GetSection("Kestrel"))` by default to load Kestrel configuration. A default HTTPS app settings configuration schema is available for Kestrel. Configure multiple endpoints, including the URLs and the certificates to use, either from a file on disk or from a certificate store.

In the following *appsettings.json* example:

- Set **AllowInvalid** to `true` to permit the use of invalid certificates (for example, self-signed certificates).
- Any HTTPS endpoint that doesn't specify a certificate (**HttpsDefaultCert** in the example that follows) falls back to the cert defined under **Certificates > Default** or the development certificate.

```
{  
  "Kestrel": {  
    "EndPoints": {  
      "Http": {  
        "Url": "http://localhost:5000"  
      },  
  
      "HttpsInlineCertFile": {  
        "Url": "https://localhost:5001",  
        "Certificate": {  
          "Path": "<path to .pfx file>",  
          "Password": "<certificate password>"  
        }  
      },  
  
      "HttpsInlineCertStore": {  
        "Url": "https://localhost:5002",  
        "Certificate": {  
          "Subject": "<subject; required>",  
          "Store": "<certificate store; defaults to My>",  
          "Location": "<location; defaults to CurrentUser>",  
          "AllowInvalid": "<true or false; defaults to false>"  
        }  
      },  
  
      "HttpsDefaultCert": {  
        "Url": "https://localhost:5003"  
      },  
  
      "Https": {  
        "Url": "https://*:5004",  
        "Certificate": {  
          "Path": "<path to .pfx file>",  
          "Password": "<certificate password>"  
        }  
      }  
    },  
    "Certificates": {  
      "Default": {  
        "Path": "<path to .pfx file>",  
        "Password": "<certificate password>"  
      }  
    }  
  }  
}
```

An alternative to using **Path** and **Password** for any certificate node is to specify the certificate using certificate store fields. For example, the **Certificates > Default** certificate can be specified as:

```
"Default": {  
  "Subject": "<subject; required>",  
  "Store": "<cert store; defaults to My>",  
  "Location": "<location; defaults to CurrentUser>",  
  "AllowInvalid": "<true or false; defaults to false>"  
}
```

Schema notes:

- Endpoints names are case-insensitive. For example, `HTTPS` and `Https` are valid.
- The `Url` parameter is required for each endpoint. The format for this parameter is the same as the top-level `Urls` configuration parameter except that it's limited to a single value.
- These endpoints replace those defined in the top-level `Urls` configuration rather than adding to them. Endpoints defined in code via `Listen` are cumulative with the endpoints defined in the configuration section.
- The `Certificate` section is optional. If the `Certificate` section isn't specified, the defaults defined in earlier scenarios are used. If no defaults are available, the server throws an exception and fails to start.
- The `Certificate` section supports both **Path–Password** and **Subject–Store** certificates.
- Any number of endpoints may be defined in this way so long as they don't cause port conflicts.
- `serverOptions.Configure(context.Configuration.GetSection("Kestrel"))` returns a `KestrelConfigurationLoader` with an `.Endpoint(string name, options => { })` method that can be used to supplement a configured endpoint's settings:

```
serverOptions.Configure(context.Configuration.GetSection("Kestrel"))
    .Endpoint("HTTPS", opt =>
{
    opt.HttpsOptions.SslProtocols = SslProtocols.Tls12;
});
```

You can also directly access `KestrelServerOptions.ConfigurationLoader` to keep iterating on the existing loader, such as the one provided by [WebHost.CreateDefaultBuilder](#).

- The configuration section for each endpoint is available on the options in the `Endpoint` method so that custom settings may be read.
- Multiple configurations may be loaded by calling `serverOptions.Configure(context.Configuration.GetSection("Kestrel"))` again with another section. Only the last configuration is used, unless `Load` is explicitly called on prior instances. The metapackage doesn't call `Load` so that its default configuration section may be replaced.
- `KestrelConfigurationLoader` mirrors the `Listen` family of APIs from `KestrelServerOptions` as `Endpoint` overloads, so code and config endpoints may be configured in the same place. These overloads don't use names and only consume default settings from configuration.

*Change the defaults in code*

`ConfigureEndpointDefaults` and `ConfigureHttpsDefaults` can be used to change default settings for `ListenOptions` and `HttpsConnectionAdapterOptions`, including overriding the default certificate specified in the prior scenario. `ConfigureEndpointDefaults` and `ConfigureHttpsDefaults` should be called before any endpoints are configured.

```
options.ConfigureEndpointDefaults(opt =>
{
    opt.NoDelay = true;
});

options.ConfigureHttpsDefaults(httpsOptions =>
{
    httpsOptions.SslProtocols = SslProtocols.Tls12;
});
```

*Kestrel support for SNI*

[Server Name Indication \(SNI\)](#) can be used to host multiple domains on the same IP address and port. For SNI to function, the client sends the host name for the secure session to the server during the TLS handshake so

that the server can provide the correct certificate. The client uses the furnished certificate for encrypted communication with the server during the secure session that follows the TLS handshake.

Kestrel supports SNI via the `ServerCertificateSelector` callback. The callback is invoked once per connection to allow the app to inspect the host name and select the appropriate certificate.

SNI support requires:

- Running on target framework `netcoreapp2.1`. On `netcoreapp2.0` and `net461`, the callback is invoked but the `name` is always `null`. The `name` is also `null` if the client doesn't provide the host name parameter in the TLS handshake.
- All websites run on the same Kestrel instance. Kestrel doesn't support sharing an IP address and port across multiple instances without a reverse proxy.

```
WebHost.CreateDefaultBuilder()
    .UseKestrel((context, options) =>
{
    options.ListenAnyIP(5005, listenOptions =>
{
    listenOptions.UseHttps(httpsOptions =>
{
    var localhostCert = CertificateLoader.LoadFromStoreCert(
        "localhost", "My", StoreLocation.CurrentUser,
        allowInvalid: true);
    var exampleCert = CertificateLoader.LoadFromStoreCert(
        "example.com", "My", StoreLocation.CurrentUser,
        allowInvalid: true);
    var subExampleCert = CertificateLoader.LoadFromStoreCert(
        "sub.example.com", "My", StoreLocation.CurrentUser,
        allowInvalid: true);
    var certs = new Dictionary(StringComparer.OrdinalIgnoreCase);
    certs["localhost"] = localhostCert;
    certs["example.com"] = exampleCert;
    certs["sub.example.com"] = subExampleCert;

    httpsOptions.ServerCertificateSelector = (connectionContext, name) =>
{
    if (name != null && certs.TryGetValue(name, out var cert))
    {
        return cert;
    }

    return exampleCert;
};
});
});
});
});
```

## Bind to a TCP socket

The [Listen](#) method binds to a TCP socket, and an options lambda permits SSL certificate configuration:

```
public static void Main(string[] args)
{
    CreateWebHostBuilder(args).Build().Run();
}

public static IWebHostBuilder CreateWebHostBuilder(string[] args) =>
    WebHost.CreateDefaultBuilder(args)
        .UseStartup<Startup>()
        .UseKestrel(options =>
    {
        options.Listen(IPAddress.Loopback, 8000);
        options.Listen(IPAddress.Loopback, 8001, listenOptions =>
        {
            listenOptions.UseHttps("testCert.pfx", "testPassword");
        });
    });
}
```

The example configures SSL for an endpoint with [ListenOptions](#). Use the same API to configure other Kestrel settings for specific endpoints.

On Windows, self-signed certificates can be created using the [New-SelfSignedCertificate PowerShell cmdlet](#). For an unsupported example, see [UpdateIISExpressSSLForChrome.ps1](#).

On macOS, Linux, and Windows, certificates can be created using [OpenSSL](#).

## Bind to a Unix socket

Listen on a Unix socket with [ListenUnixSocket](#) for improved performance with Nginx, as shown in this example:

```
.UseKestrel(options =>
{
    options.ListenUnixSocket("/tmp/kestrel-test.sock");
    options.ListenUnixSocket("/tmp/kestrel-test.sock", listenOptions =>
    {
        listenOptions.UseHttps("testCert.pfx", "testpassword");
    });
});
```

## Port 0

When the port number `0` is specified, Kestrel dynamically binds to an available port. The following example shows how to determine which port Kestrel actually bound at runtime:

```

public void Configure(IApplicationBuilder app)
{
    var serverAddressesFeature =
        app.ServerFeatures.Get<IServerAddressesFeature>();

    app.UseStaticFiles();

    app.Run(async (context) =>
    {
        context.Response.ContentType = "text/html";
        await context.Response
            .WriteAsync("<!DOCTYPE html><html lang=\"en\"><head>" +
            "<title></title></head><body><p>Hosted by Kestrel</p>");

        if (serverAddressesFeature != null)
        {
            await context.Response
                .WriteAsync("<p>Listening on the following addresses: " +
                    string.Join(", ", serverAddressesFeature.Addresses) +
                    "</p>");
        }

        await context.Response.WriteAsync("<p>Request URL: " +
            $"{context.Request.GetDisplayUrl()}</p>");
    });
}

```

When the app is run, the console window output indicates the dynamic port where the app can be reached:

```
Listening on the following addresses: http://127.0.0.1:48508
```

## **UseUrls, --urls command-line argument, urls host configuration key, and ASPNETCORE\_URLS environment variable limitations**

Configure endpoints with the following approaches:

- `UseUrls`
- `--urls` command-line argument
- `urls` host configuration key
- `ASPNETCORE_URLS` environment variable

These methods are useful for making code work with servers other than Kestrel. However, be aware of these limitations:

- SSL can't be used with these approaches unless a default certificate is provided in the HTTPS endpoint configuration (for example, using `KestrelServerOptions` configuration or a configuration file as shown earlier in this topic).
- When both the `Listen` and `useUrls` approaches are used simultaneously, the `Listen` endpoints override the `useUrls` endpoints.

### **IIS endpoint configuration**

When using IIS, the URL bindings for IIS override bindings are set by either `Listen` or `UseUrls`. For more information, see the [ASP.NET Core Module](#) topic.

## **Transport configuration**

With the release of ASP.NET Core 2.1, Kestrel's default transport is no longer based on Libuv but instead based on managed sockets. This is a breaking change for ASP.NET Core 2.0 apps upgrading to 2.1 that call

`WebHostBuilderExtensions.UseLibuv` and depend on either of the following packages:

- `Microsoft.AspNetCore.Server.Kestrel` (direct package reference)
- `Microsoft.AspNetCore.App`

For ASP.NET Core 2.1 or later projects that use the `Microsoft.AspNetCore.App metapackage` and require the use of Libuv:

- Add a dependency for the `Microsoft.AspNetCore.Server.Kestrel.Transport.Libuv` package to the app's project file:

```
<PackageReference Include="Microsoft.AspNetCore.Server.Kestrel.Transport.Libuv"
Version="2.1.0" />
```

- Call `WebHostBuilderExtensions.UseLibuv`:

```
public class Program
{
    public static void Main(string[] args)
    {
        CreateWebHostBuilder(args).Build().Run();
    }

    public static IWebHostBuilder CreateWebHostBuilder(string[] args) =>
        WebHost.CreateDefaultBuilder(args)
            .UseLibuv()
            .UseStartup<Startup>();
}
```

## URL prefixes

When using `UseUrls`, `--urls` command-line argument, `urls` host configuration key, or `ASPNETCORE_URLS` environment variable, the URL prefixes can be in any of the following formats.

- [ASP.NET Core 2.x](#)
- [ASP.NET Core 1.x](#)

Only HTTP URL prefixes are valid. Kestrel doesn't support SSL when configuring URL bindings using `UseUrls`.

- IPv4 address with port number

```
http://65.55.39.10:80/
```

`0.0.0.0` is a special case that binds to all IPv4 addresses.

- IPv6 address with port number

```
http://[0:0:0:0:0:ffff:4137:270a]:80/
```

`[::]` is the IPv6 equivalent of IPv4 `0.0.0.0`.

- Host name with port number

```
http://contoso.com:80/
http://*:80/
```

Host names, `*`, and `+`, aren't special. Anything not recognized as a valid IP address or `localhost` binds to all IPv4 and IPv6 IPs. To bind different host names to different ASP.NET Core apps on the same port, use [HTTP.sys](#) or a reverse proxy server, such as IIS, Nginx, or Apache.

#### WARNING

If not using a reverse proxy with host filtering enabled, enable [host filtering](#).

- Host `localhost` name with port number or loopback IP with port number

```
http://localhost:5000/  
http://127.0.0.1:5000/  
http://[::1]:5000/
```

When `localhost` is specified, Kestrel attempts to bind to both IPv4 and IPv6 loopback interfaces. If the requested port is in use by another service on either loopback interface, Kestrel fails to start. If either loopback interface is unavailable for any other reason (most commonly because IPv6 isn't supported), Kestrel logs a warning.

## Host filtering

While Kestrel supports configuration based on prefixes such as `http://example.com:5000`, Kestrel largely ignores the host name. Host `localhost` is a special case used for binding to loopback addresses. Any host other than an explicit IP address binds to all public IP addresses. None of this information is used to validate request `Host` headers.

As a workaround, host behind a reverse proxy with host header filtering. This is the only supported scenario for Kestrel in ASP.NET Core 1.x.

As a workaround, use middleware to filter requests by the `Host` header:

```
using Microsoft.AspNetCore.Http;  
using Microsoft.Extensions.Configuration;  
using Microsoft.Extensions.Logging;  
using Microsoft.Extensions.Primitives;  
using Microsoft.Net.Http.Headers;  
using System;  
using System.Collections.Generic;  
using System.Threading.Tasks;  
  
// A normal middleware would provide an options type, config binding, extension methods, etc..  
// This intentionally does all of the work inside of the middleware so it can be  
// easily copy-pasted into docs and other projects.  
public class HostFilteringMiddleware  
{  
    private readonly RequestDelegate _next;  
    private readonly IList<string> _hosts;  
    private readonly ILogger<HostFilteringMiddleware> _logger;  
  
    public HostFilteringMiddleware(RequestDelegate next, IConfiguration config,  
        ILogger<HostFilteringMiddleware> logger)  
    {  
        if (config == null)  
        {  
            throw new ArgumentNullException(nameof(config));  
        }  
  
        _next = next ?? throw new ArgumentNullException(nameof(next));  
        _logger = logger ?? throw new ArgumentNullException(nameof(logger));  
    }
```

```

// A semicolon separated list of host names without the port numbers.
// IPv6 addresses must use the bounding brackets and be in their normalized form.
_hosts = config["AllowedHosts"]?.Split(new[] { ';' }, StringSplitOptions.RemoveEmptyEntries);
if (_hosts == null || _hosts.Count == 0)
{
    throw new InvalidOperationException("No configuration entry found for AllowedHosts.");
}

public Task Invoke(HttpContext context)
{
    if (!ValidateHost(context))
    {
        context.Response.StatusCode = 400;
        _logger.LogDebug("Request rejected due to incorrect Host header.");
        return Task.CompletedTask;
    }

    return _next(context);
}

// This does not duplicate format validations that are expected to be performed by the host.
private bool ValidateHost(HttpContext context)
{
    StringSegment host = context.Request.Headers[HeaderNames.Host].ToString().Trim();

    if (StringSegment.IsNullOrEmpty(host))
    {
        // Http/1.0 does not require the Host header.
        // Http/1.1 requires the header but the value may be empty.
        return true;
    }

    // Drop the port

    var colonIndex = host.LastIndexOf(':');

    // IPv6 special case
    if (host.StartsWith("[", StringComparison.OrdinalIgnoreCase))
    {
        var endBracketIndex = host.IndexOf(']');
        if (endBracketIndex < 0)
        {
            // Invalid format
            return false;
        }
        if (colonIndex < endBracketIndex)
        {
            // No port, just the IPv6 Host
            colonIndex = -1;
        }
    }

    if (colonIndex > 0)
    {
        host = host.Subsegment(0, colonIndex);
    }

    foreach (var allowedHost in _hosts)
    {
        if (StringSegment.Equals(allowedHost, host, StringComparison.OrdinalIgnoreCase))
        {
            return true;
        }
    }

    // Sub-domain wildcards: *.example.com
    if (allowedHost.StartsWith("*.", StringComparison.OrdinalIgnoreCase) && host.Length >= allowedHost.Length)
    {
        return true;
    }
}

```

```
// .example.com
var allowedRoot = new StringSegment(allowedHost, 1, allowedHost.Length - 1);

var hostRoot = host.Subsegment(host.Length - allowedRoot.Length, allowedRoot.Length);
if (hostRoot.Equals(allowedRoot, StringComparison.OrdinalIgnoreCase))
{
    return true;
}
}

return false;
}
}
```

Register the preceding `HostFilteringMiddleware` in `Startup.Configure`. Note that the [ordering of middleware registration](#) is important. Registration should occur immediately after Diagnostic Middleware registration (for example, `app.UseExceptionHandler`).

```
public void Configure(IApplicationBuilder app, IHostingEnvironment env)
{
    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
        app.UseBrowserLink();
    }
    else
    {
        app.UseExceptionHandler("/Home/Error");
    }

    app.UseMiddleware<HostFilteringMiddleware>();

    app.UseMvcWithDefaultRoute();
}
```

The middleware expects an `AllowedHosts` key in `appsettings.json/appsettings.<EnvironmentName>.json`. The value is a semicolon-delimited list of host names without port numbers:

As a workaround, use Host Filtering Middleware. Host Filtering Middleware is provided by the [Microsoft.AspNetCore.HostFiltering](#) package, which is included in the [Microsoft.AspNetCore.App](#) metapackage (ASP.NET Core 2.1 or later). The middleware is added by `CreateDefaultBuilder`, which calls `AddHostFiltering`:

```
public class Program
{
    public static void Main(string[] args)
    {
        CreateWebHostBuilder(args).Build().Run();
    }

    public static IWebHostBuilder CreateWebHostBuilder(string[] args) =>
        WebHost.CreateDefaultBuilder(args)
            .UseStartup<Startup>();
}
```

Host Filtering Middleware is disabled by default. To enable the middleware, define an `AllowedHosts` key in `appsettings.json/appsettings.<EnvironmentName>.json`. The value is a semicolon-delimited list of host names without port numbers:

`appsettings.json`:

```
{  
  "AllowedHosts": "example.com;localhost"  
}
```

#### NOTE

Forwarded Headers Middleware also has an `ForwardedHeadersOptions.AllowedHosts` option. Forwarded Headers Middleware and Host Filtering Middleware have similar functionality for different scenarios. Setting `AllowedHosts` with Forwarded Headers Middleware is appropriate when the Host header isn't preserved while forwarding requests with a reverse proxy server or load balancer. Setting `AllowedHosts` with Host Filtering Middleware is appropriate when Kestrel is used as an edge server or when the Host header is directly forwarded.

For more information on Forwarded Headers Middleware, see [Configure ASP.NET Core to work with proxy servers and load balancers](#).

# ASP.NET Core Module

6/21/2018 • 2 minutes to read • [Edit Online](#)

By [Tom Dykstra](#), [Rick Strahl](#), and [Chris Ross](#)

The ASP.NET Core Module allows ASP.NET Core apps to run behind IIS in a reverse proxy configuration. IIS provides advanced web app security and manageability features.

Supported Windows versions:

- Windows 7 or later
- Windows Server 2008 R2 or later

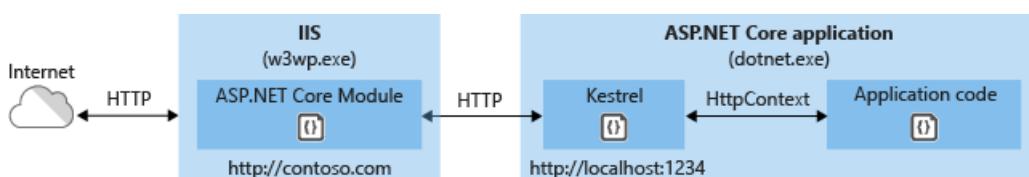

The ASP.NET Core Module only works with Kestrel. The module is incompatible with [HTTP.sys](#) (formerly called [WebListener](#)).

## ASP.NET Core Module description

The ASP.NET Core Module is a native IIS module that plugs into the IIS pipeline to redirect web requests to backend ASP.NET Core apps. Many native modules, such as Windows Authentication, remain active. To learn more about IIS modules active with the module, see [IIS modules](#).

Because ASP.NET Core apps run in a process separate from the IIS worker process, the module also handles process management. The module starts the process for the ASP.NET Core app when the first request arrives and restarts the app if it crashes. This is essentially the same behavior as seen with ASP.NET 4.x apps that run in-process in IIS that are managed by the [Windows Process Activation Service \(WAS\)](#).

The following diagram illustrates the relationship between IIS, the ASP.NET Core Module, and ASP.NET Core apps:

Requests arrive from the web to the kernel-mode HTTP.sys driver. The driver routes the requests to IIS on the website's configured port, usually 80 (HTTP) or 443 (HTTPS). The module forwards the requests to Kestrel on a random port for the app, which isn't port 80/443.

The module specifies the port via an environment variable at startup, and the IIS Integration Middleware configures the server to listen on `http://localhost:{port}`. Additional checks are performed, and requests that don't originate from the module are rejected. The module doesn't support HTTPS forwarding, so requests are forwarded over HTTP even if received by IIS over HTTPS.

After Kestrel picks up a request from the module, the request is pushed into the ASP.NET Core middleware pipeline. The middleware pipeline handles the request and passes it on as an `HttpContext` instance to the app's logic. The app's response is passed back to IIS, which pushes it back out to the HTTP client that initiated the request.

The ASP.NET Core Module has a few other functions. The module can:

- Set environment variables for the worker process.
- Log stdout output to file storage for troubleshooting startup issues.

- Forward Windows authentication tokens.

## How to install and use the ASP.NET Core Module

For detailed instructions on how to install and use the ASP.NET Core Module, see [Host on Windows with IIS](#).

For information on configuring the module, see the [ASP.NET Core Module configuration reference](#).

# HTTP.sys web server implementation in ASP.NET Core

6/21/2018 • 6 minutes to read • [Edit Online](#)

By [Tom Dykstra](#), [Chris Ross](#), and [Luke Latham](#)

## NOTE

This topic applies to ASP.NET Core 2.0 or later. In earlier versions of ASP.NET Core, HTTP.sys is named [WebListener](#).

HTTP.sys is a [web server for ASP.NET Core](#) that only runs on Windows. HTTP.sys is an alternative to [Kestrel](#) and offers some features that Kestrel doesn't provide.

## IMPORTANT

HTTP.sys is incompatible with the [ASP.NET Core Module](#) and can't be used with IIS or IIS Express.

HTTP.sys supports the following features:

- [Windows Authentication](#)
- Port sharing
- HTTPS with SNI
- HTTP/2 over TLS (Windows 10 or later)
- Direct file transmission
- Response caching
- WebSockets (Windows 8 or later)

Supported Windows versions:

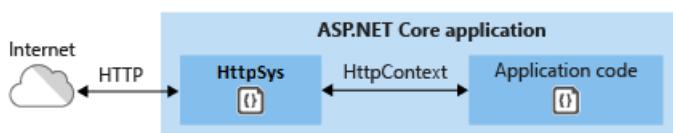

- Windows 7 or later
- Windows Server 2008 R2 or later

[View or download sample code \(how to download\)](#)

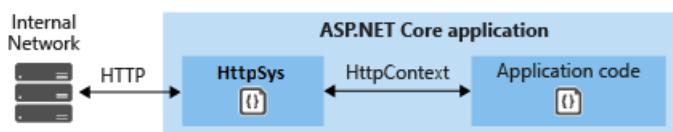

## When to use HTTP.sys

HTTP.sys is useful for deployments where:

- There's a need to expose the server directly to the Internet without using IIS.

- An internal deployment requires a feature not available in Kestrel, such as [Windows Authentication](#).

HTTP.sys is a mature technology that protects against many types of attacks and provides the robustness, security, and scalability of a full-featured web server. IIS itself runs as an HTTP listener on top of HTTP.sys.

## How to use HTTP.sys

### Configure the ASP.NET Core app to use HTTP.sys

1. A package reference in the project file isn't required when using the [Microsoft.AspNetCore.App metapackage \(nuget.org\)](#) (ASP.NET Core 2.1 or later). When not using the [Microsoft.AspNetCore.App](#) metapackage, add a package reference to [Microsoft.AspNetCore.Server.HttpSys](#).
2. Call the [UseHttpSys](#) extension method when building the web host, specifying any required [HTTP.sys options](#):

```
public static IWebHostBuilder CreateWebHostBuilder(string[] args) =>
    WebHost.CreateDefaultBuilder(args)
        .UseStartup<Startup]()
        .UseHttpSys(options =>
    {
        // The following options are set to default values.
        options.Authentication.Schemes = AuthenticationSchemes.None;
        options.Authentication.AllowAnonymous = true;
        options.MaxConnections = null;
        options.MaxRequestBodySize = 30000000;
        options.UrlPrefixes.Add("http://localhost:5000");
    });
}
```

Additional HTTP.sys configuration is handled through [registry settings](#).

### HTTP.sys options

PROPERTY	DESCRIPTION	DEFAULT
AllowSynchronousIO	Control whether synchronous input/output is allowed for the <a href="#">HttpContext.Request.Body</a> and <a href="#">HttpContext.Response.Body</a> .	true
Authentication.AllowAnonymous	Allow anonymous requests.	true
Authentication.Schemes	Specify the allowed authentication schemes. May be modified at any time prior to disposing the listener. Values are provided by the <a href="#">AuthenticationSchemes enum</a> : <a href="#">Basic</a> , <a href="#">Kerberos</a> , <a href="#">Negotiate</a> , <a href="#">None</a> , and <a href="#">NTLM</a> .	None
EnableResponseCaching	Attempt <a href="#">kernel-mode</a> caching for responses with eligible headers. The response may not include <a href="#">Set-Cookie</a> , <a href="#">Vary</a> , or <a href="#">Pragma</a> headers. It must include a <a href="#">Cache-Control</a> header that's <a href="#">public</a> and either a <a href="#">shared-max-age</a> or <a href="#">max-age</a> value, or an <a href="#">Expires</a> header.	true

PROPERTY	DESCRIPTION	DEFAULT
MaxAccepts	The maximum number of concurrent accepts.	5 × <a href="#">Environment.ProcessorCount</a>
MaxConnections	The maximum number of concurrent connections to accept. Use <code>-1</code> for infinite. Use <code>null</code> to use the registry's machine-wide setting.	<code>null</code> (unlimited)
MaxRequestBodySize	See the <a href="#">MaxRequestBodySize</a> section.	30000000 bytes (~28.6 MB)
RequestQueueLimit	The maximum number of requests that can be queued.	1000
ThrowWriteExceptions	Indicate if response body writes that fail due to client disconnects should throw exceptions or complete normally.	<code>false</code> (complete normally)
Timeouts	<p>Expose the HTTP.sys <a href="#">TimeoutManager</a> configuration, which may also be configured in the registry. Follow the API links to learn more about each setting, including default values:</p> <ul style="list-style-type: none"> <li>• <a href="#">Timeouts.DrainEntityBody</a> – Time allowed for the HTTP Server API to drain the entity body on a Keep-Alive connection.</li> <li>• <a href="#">Timeouts.EntityBody</a> – Time allowed for the request entity body to arrive.</li> <li>• <a href="#">Timeouts.HeaderWait</a> – Time allowed for the HTTP Server API to parse the request header.</li> <li>• <a href="#">Timeouts.IdleConnection</a> – Time allowed for an idle connection.</li> <li>• <a href="#">Timeouts.MinSendBytesPerSecond</a> – The minimum send rate for the response.</li> <li>• <a href="#">Timeouts.RequestQueue</a> – Time allowed for the request to remain in the request queue before the app picks it up.</li> </ul>	
UrlPrefixes	Specify the <a href="#">UrlPrefixCollection</a> to register with HTTP.sys. The most useful is <a href="#">UrlPrefixCollection.Add</a> , which is used to add a prefix to the collection. These may be modified at any time prior to disposing the listener.	

## MaxRequestBodySize

The maximum allowed size of any request body in bytes. When set to `null`, the maximum request body size is unlimited. This limit has no effect on upgraded connections, which are always unlimited.

The recommended method to override the limit in an ASP.NET Core MVC app for a single `IActionResult` is to use the [RequestSizeLimitAttribute](#) attribute on an action method:

```
[RequestSizeLimit(100000000)]
public IActionResult MyActionMethod()
```

An exception is thrown if the app attempts to configure the limit on a request after the app has started reading the request. An `IsReadOnly` property can be used to indicate if the `MaxRequestBodySize` property is in a read-only state, meaning it's too late to configure the limit.

If the app should override `MaxRequestBodySize` per-request, use the [IHttpMaxRequestBodySizeFeature](#):

```
public void Configure(IApplicationBuilder app, IHostingEnvironment env,
    ILogger<Startup> logger)
{
    app.Use(async (context, next) =>
    {
        context.Features.Get< IHttpMaxRequestBodySizeFeature >()
            .MaxRequestBodySize = 10 * 1024;

        var serverAddressesFeature = app.ServerFeatures.Get< IServerAddressesFeature >();
        var addresses = string.Join(", ", serverAddressesFeature?.Addresses);

        logger.LogInformation($"Addresses: {addresses}");

        await next.Invoke();
    });

    if (env.IsDevelopment())
    {
        app.UseDeveloperExceptionPage();
        app.UseDatabaseErrorPage();
    }
    else
    {
        app.UseExceptionHandler("/Error");
        app.UseHsts();
    }

    // Enable HTTPS Redirection Middleware when hosting the app securely.
    //app.UseHttpsRedirection();
    app.UseStaticFiles();
    app.UseCookiePolicy();
    app.UseMvc();
}
```

3. If using Visual Studio, make sure the app isn't configured to run IIS or IIS Express.

In Visual Studio, the default launch profile is for IIS Express. To run the project as a console app, manually change the selected profile, as shown in the following screen shot:

## Configure Windows Server

1. If the app is a [framework-dependent deployment](#), install .NET Core, .NET Framework, or both (if the app is a .NET Core app targeting the .NET Framework).
  - **.NET Core** – If the app requires .NET Core, obtain and run the .NET Core installer from [.NET All Downloads](#).
  - **.NET Framework** – If the app requires .NET Framework, see [.NET Framework: Installation guide](#) to find installation instructions. Install the required .NET Framework. The installer for the latest .NET Framework can be found at [.NET All Downloads](#).
2. Configure URLs and ports for the app.

By default, ASP.NET Core binds to `http://localhost:5000`. To configure URL prefixes and ports, options include using:

- `UseUrls`
- `urls` command-line argument
- `ASPNETCORE_URLS` environment variable
- [UrlPrefixes](#)

The following code example shows how to use [UrlPrefixes](#):

```
public static IWebHostBuilder CreateWebHostBuilder(string[] args) =>
    WebHost.CreateDefaultBuilder(args)
        .UseStartup<Startup>()
        .UseHttpSys(options =>
    {
        // The following options are set to default values.
        options.Authentication.Schemes = AuthenticationSchemes.None;
        options.Authentication.AllowAnonymous = true;
        options.MaxConnections = null;
        options.MaxRequestBodySize = 30000000;
        options.UrlPrefixes.Add("http://localhost:5000");
    });
}
```

An advantage of `UrlPrefixes` is that an error message is generated immediately for improperly formatted prefixes.

The settings in `UrlPrefixes` override `UseUrls` / `urls` / `ASPNETCORE_URLS` settings. Therefore, an advantage of `UseUrls`, `urls`, and the `ASPNETCORE_URLS` environment variable is that it's easier to switch between Kestrel and HTTP.sys. For more information on `UseUrls`, `urls`, and `ASPNETCORE_URLS`, see the [Host in ASP.NET Core](#) topic.

HTTP.sys uses the [HTTP Server API UrlPrefix string formats](#).

#### WARNING

Top-level wildcard bindings (`http://*:80/` and `http://+:80`) should **not** be used. Top-level wildcard bindings can open up your app to security vulnerabilities. This applies to both strong and weak wildcards. Use explicit host names rather than wildcards. Subdomain wildcard binding (for example, `*.mysub.com`) doesn't have this security risk if you control the entire parent domain (as opposed to `.com`, which is vulnerable). See [rfc7230 section-5.4](#) for more information.

### 3. Preregister URL prefixes to bind to HTTP.sys and set up X.509 certificates.

If URL prefixes aren't preregistered in Windows, run the app with administrator privileges. The only exception is when binding to localhost using HTTP (not HTTPS) with a port number greater than 1024. In that case, administrator privileges aren't required.

- a. The built-in tool for configuring HTTP.sys is `netsh.exe`. `netsh.exe` is used to reserve URL prefixes and assign X.509 certificates. The tool requires administrator privileges.

The following example shows the commands to reserve URL prefixes for ports 80 and 443:

```
netsh http add urlacl url=http://+:80/ user=Users  
netsh http add urlacl url=https://+:443/ user=Users
```

The following example shows how to assign an X.509 certificate:

```
netsh http add sslcert ipport=0.0.0.0:443 certhash=MyCertHash_Here appid="{00000000-0000-0000-  
0000-000000000000}"
```

Reference documentation for `netsh.exe`:

- [Netsh Commands for Hypertext Transfer Protocol \(HTTP\)](#)
- [UrlPrefix Strings](#)

- b. Create self-signed X.509 certificates, if required.

On Windows, self-signed certificates can be created using the [New-SelfSignedCertificate PowerShell cmdlet](#). For an unsupported example, see [UpdateIISExpressSSLForChrome.ps1](#).

On macOS, Linux, and Windows, certificates can be created using [OpenSSL](#).

### 4. Open firewall ports to allow traffic to reach HTTP.sys. Use `netsh.exe` or [PowerShell cmdlets](#).

## Proxy server and load balancer scenarios

For apps hosted by HTTP.sys that interact with requests from the Internet or a corporate network, additional configuration might be required when hosting behind proxy servers and load balancers. For more information, see [Configure ASP.NET Core to work with proxy servers and load balancers](#).

# Globalization and localization in ASP.NET Core

7/3/2018 • 16 minutes to read • [Edit Online](#)

By [Rick Anderson](#), [Damien Bowden](#), [Bart Calixto](#), [Nadeem Afana](#), and [Hisham Bin Ateya](#)

Creating a multilingual website with ASP.NET Core will allow your site to reach a wider audience. ASP.NET Core provides services and middleware for localizing into different languages and cultures.

Internationalization involves [Globalization](#) and [Localization](#). Globalization is the process of designing apps that support different cultures. Globalization adds support for input, display, and output of a defined set of language scripts that relate to specific geographic areas.

Localization is the process of adapting a globalized app, which you have already processed for localizability, to a particular culture/locale. For more information see **Globalization and localization terms** near the end of this document.

App localization involves the following:

1. Make the app's content localizable
2. Provide localized resources for the languages and cultures you support
3. Implement a strategy to select the language/culture for each request

## Make the app's content localizable

Introduced in ASP.NET Core, `IStringLocalizer` and `IStringLocalizer<T>` were architected to improve productivity when developing localized apps. `IStringLocalizer` uses the [ResourceManager](#) and [ResourceReader](#) to provide culture-specific resources at run time. The simple interface has an indexer and an `IEnumerable` for returning localized strings. `IStringLocalizer` doesn't require you to store the default language strings in a resource file. You can develop an app targeted for localization and not need to create resource files early in development. The code below shows how to wrap the string "About Title" for localization.

```
using Microsoft.AspNetCore.Mvc;
using Microsoft.Extensions.Localization;

namespace Localization.StarterWeb.Controllers
{
    [Route("api/[controller]")]
    public class AboutController : Controller
    {
        private readonly IStringLocalizer<AboutController> _localizer;

        public AboutController(IStringLocalizer<AboutController> localizer)
        {
            _localizer = localizer;
        }

        [HttpGet]
        public string Get()
        {
            return _localizer["About Title"];
        }
    }
}
```

In the code above, the `IStringLocalizer<T>` implementation comes from [Dependency Injection](#). If the localized value of "About Title" isn't found, then the indexer key is returned, that is, the string "About Title". You can leave the default language literal strings in the app and wrap them in the localizer, so that you can focus on developing the app. You develop your app with your default language and prepare it for the localization step without first creating a default resource file. Alternatively, you can use the traditional approach and provide a key to retrieve the default language string. For many developers the new workflow of not having a default language .resx file and simply wrapping the string literals can reduce the overhead of localizing an app. Other developers will prefer the traditional work flow as it can make it easier to work with longer string literals and make it easier to update localized strings.

Use the `IHtmlLocalizer<T>` implementation for resources that contain HTML. `IHtmlLocalizer` HTML encodes arguments that are formatted in the resource string, but doesn't HTML encode the resource string itself. In the sample highlighted below, only the value of `name` parameter is HTML encoded.

```
using System;
using Microsoft.AspNetCore.Http;
using Microsoft.AspNetCore.Localization;
using Microsoft.AspNetCore.Mvc;
using Microsoft.AspNetCore.Mvc.Localization;

namespace Localization.StarterWeb.Controllers
{
    public class BookController : Controller
    {
        private readonly IHtmlLocalizer<BookController> _localizer;

        public BookController(IHtmlLocalizer<BookController> localizer)
        {
            _localizer = localizer;
        }

        public IActionResult Hello(string name)
        {
            ViewData["Message"] = _localizer["<b>Hello</b><i> {0}</i>", name];

            return View();
        }
    }
}
```

**Note:** You generally want to only localize text and not HTML.

At the lowest level, you can get `IStringLocalizerFactory` out of [Dependency Injection](#):

```
{
    public class TestController : Controller
    {
        private readonly IStringLocalizer _localizer;
        private readonly IStringLocalizer _localizer2;

        public TestController(IStringLocalizerFactory factory)
        {
            var type = typeof(SharedResource);
            var assemblyName = new AssemblyName(type.GetTypeInfo().Assembly.FullName);
            _localizer = factory.Create(type);
            _localizer2 = factory.Create("SharedResource", assemblyName.Name);
        }

        public IActionResult About()
        {
            ViewData["Message"] = _localizer["Your application description page."]
                + " loc 2: " + _localizer2["Your application description page."];
        }
    }
}
```

The code above demonstrates each of the two factory create methods.

You can partition your localized strings by controller, area, or have just one container. In the sample app, a dummy class named `SharedResource` is used for shared resources.

```
// Dummy class to group shared resources

namespace Localization.StarterWeb
{
    public class SharedResource
    {
    }
}
```

Some developers use the `Startup` class to contain global or shared strings. In the sample below, the `InfoController` and the `SharedResource` localizers are used:

```
public class InfoController : Controller
{
    private readonly IStringLocalizer<InfoController> _localizer;
    private readonly IStringLocalizer<SharedResource> _sharedLocalizer;

    public InfoController(IStringLocalizer<InfoController> localizer,
                          IStringLocalizer<SharedResource> sharedLocalizer)
    {
        _localizer = localizer;
        _sharedLocalizer = sharedLocalizer;
    }

    public string TestLoc()
    {
        string msg = "Shared resx: " + _sharedLocalizer["Hello!"] +
                    " Info resx " + _localizer["Hello!"];
        return msg;
    }
}
```

## View localization

The `IViewLocalizer` service provides localized strings for a `view`. The `ViewLocalizer` class implements this interface and finds the resource location from the view file path. The following code shows how to use the default implementation of `IViewLocalizer`:

```
@using Microsoft.AspNetCore.Mvc.Localization

@inject IViewLocalizer Localizer

@{
    ViewData["Title"] = Localizer["About"];
}
<h2>@ViewData["Title"].</h2>
<h3>@ViewData["Message"]</h3>

<p>@Localizer["Use this area to provide additional information."]</p>
```

The default implementation of `IViewLocalizer` finds the resource file based on the view's file name. There's no option to use a global shared resource file. `ViewLocalizer` implements the localizer using `IHtmlLocalizer`, so Razor doesn't HTML encode the localized string. You can parameterize resource strings and `IViewLocalizer` will HTML encode the parameters, but not the resource string. Consider the following Razor markup:

```
@Localizer["<i>Hello</i> <b>{0}</b>", UserManager.GetUserName(User)]
```

A French resource file could contain the following:

KEY	VALUE
<i>Hello</i> <b>{0}</b>	<i>Bonjour</i> <b>{0}</b>

The rendered view would contain the HTML markup from the resource file.

**Note:** You generally want to only localize text and not HTML.

To use a shared resource file in a view, inject `IHtmlLocalizer<T>`:

```
@using Microsoft.AspNetCore.Mvc.Localization
@using Localization.StarterWeb.Services

@inject IViewLocalizer Localizer
@inject IHtmlLocalizer<SharedResource> SharedLocalizer

@{
    ViewData["Title"] = Localizer["About"];
}

<h2>@ViewData["Title"].</h2>

<h1>@SharedLocalizer["Hello!"]</h1>
```

## DataAnnotations localization

DataAnnotations error messages are localized with `IStringLocalizer<T>`. Using the option

`ResourcesPath = "Resources"`, the error messages in `RegisterViewModel` can be stored in either of the following paths:

- `Resources/ViewModels/Account/RegisterViewModel.fr.resx`
- `Resources/ViewModels/Account/RegisterViewModel.fr.resx`

```
public class RegisterViewModel
{
    [Required(ErrorMessage = "The Email field is required.")]
    [EmailAddress(ErrorMessage = "The Email field is not a valid email address.")]
    [Display(Name = "Email")]
    public string Email { get; set; }

    [Required(ErrorMessage = "The Password field is required.")]
    [StringLength(8, ErrorMessage = "The {0} must be at least {2} characters long.", MinimumLength = 6)]
    [DataType(DataType.Password)]
    [Display(Name = "Password")]
    public string Password { get; set; }

    [DataType(DataType.Password)]
    [Display(Name = "Confirm password")]
    [Compare("Password", ErrorMessage = "The password and confirmation password do not match.")]
    public string ConfirmPassword { get; set; }
}
```

In ASP.NET Core MVC 1.1.0 and higher, non-validation attributes are localized. ASP.NET Core MVC 1.0 does **not** look up localized strings for non-validation attributes.

## Using one resource string for multiple classes

The following code shows how to use one resource string for validation attributes with multiple classes:

```
public void ConfigureServices(IServiceCollection services)
{
    services.AddMvc()
        .AddDataAnnotationsLocalization(options => {
            options.DataAnnotationLocalizerProvider = (type, factory) =>
                factory.Create(typeof(SharedResource));
        });
}
```

In the preceding code, `SharedResource` is the class corresponding to the resx where your validation messages are stored. With this approach, DataAnnotations will only use `sharedResource`, rather than the resource for each class.

## Provide localized resources for the languages and cultures you support

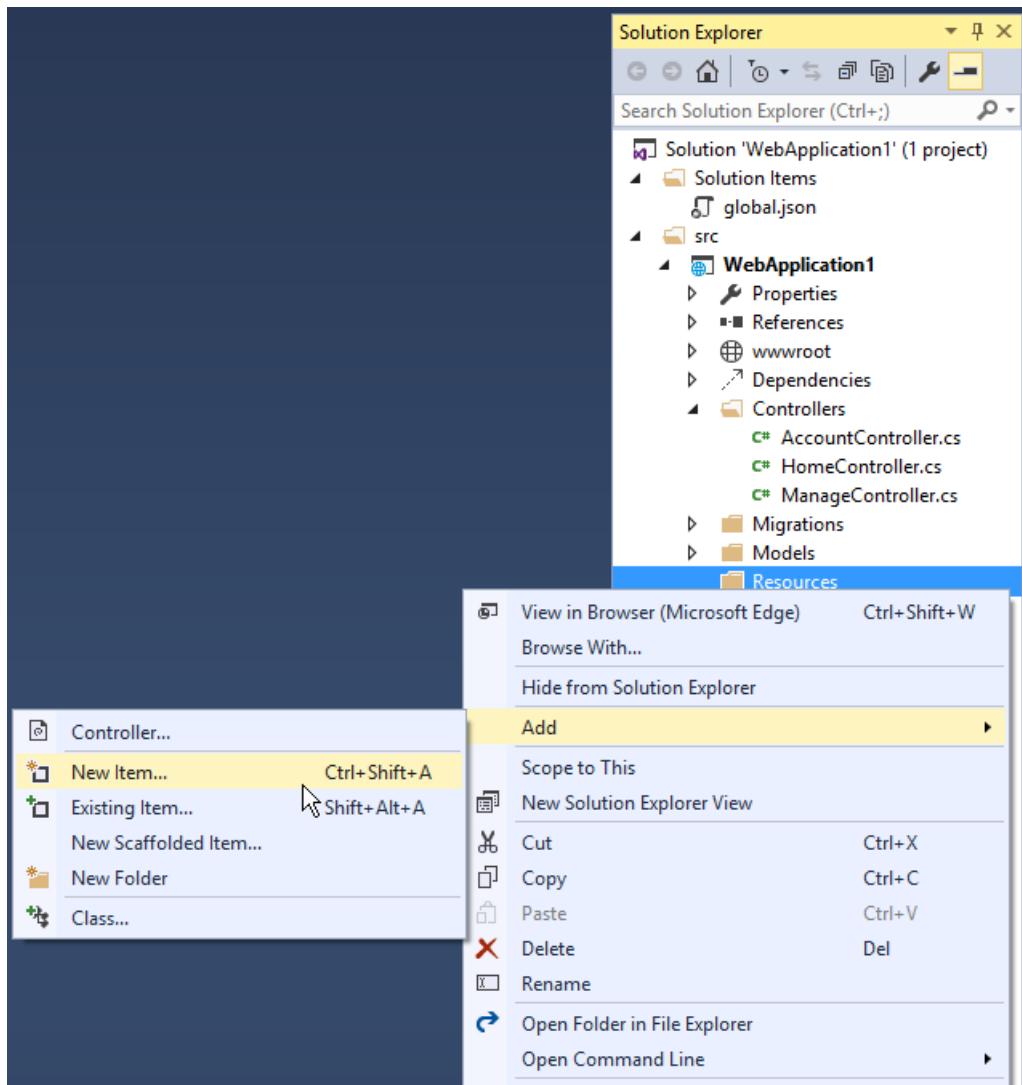

### SupportedCultures and SupportedUICultures

ASP.NET Core allows you to specify two culture values, `SupportedCultures` and `SupportedUICultures`. The `CultureInfo` object for `SupportedCultures` determines the results of culture-dependent functions, such as date, time, number, and currency formatting. `SupportedCultures` also determines the sorting order of text, casing conventions, and string comparisons. See [CultureInfo.CurrentCulture](#) for more info on how the server gets the Culture. The `SupportedUICultures` determines which translates strings (from .resx files) are looked up by the `ResourceManager`. The `ResourceManager` simply looks up culture-specific strings that's determined by `CurrentUICulture`. Every thread in .NET has `CurrentCulture` and `CurrentUICulture` objects. ASP.NET Core inspects these values when rendering culture-dependent functions. For example, if the current thread's culture is set to "en-US" (English, United States), `DateTime.Now.ToString("dddd, dd MMMM yyyy")` displays "Thursday, February 18, 2016", but if `CurrentCulture` is set to "es-ES" (Spanish, Spain) the output will be "jueves, 18 de febrero de 2016".

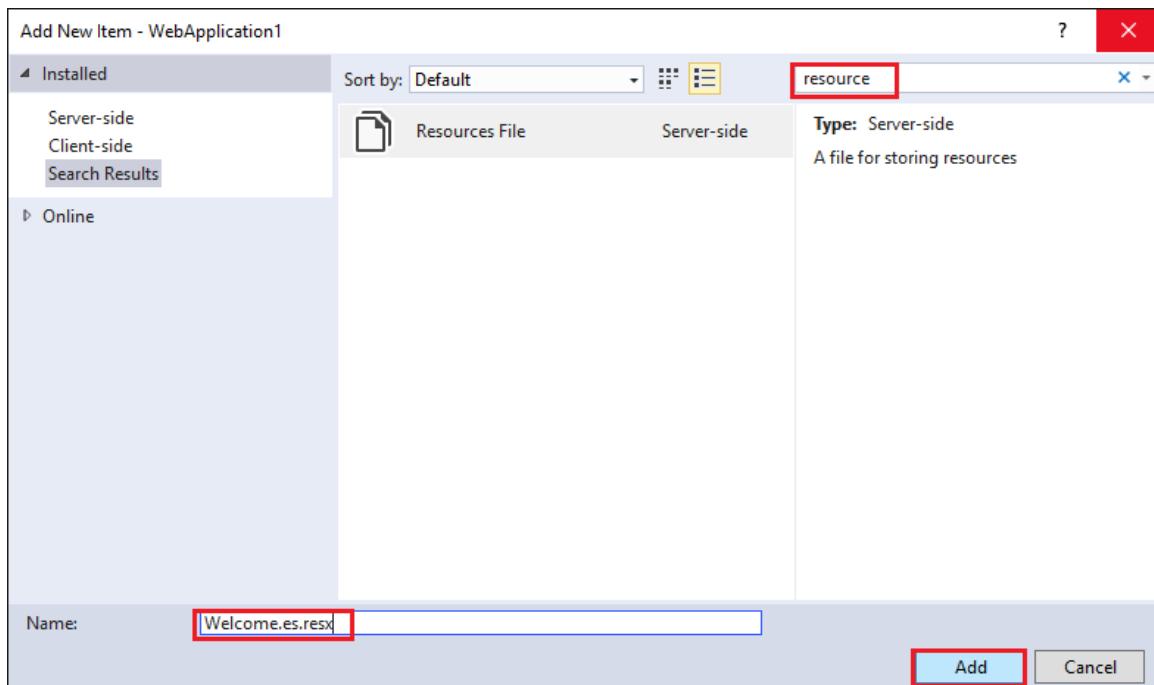

## Resource files

A resource file is a useful mechanism for separating localizable strings from code. Translated strings for the non-default language are isolated .resx resource files. For example, you might want to create Spanish resource file named *Welcome.es.resx* containing translated strings. "es" is the language code for Spanish. To create this resource file in Visual Studio:

1. In **Solution Explorer**, right click on the folder which will contain the resource file > **Add** > **New Item**.

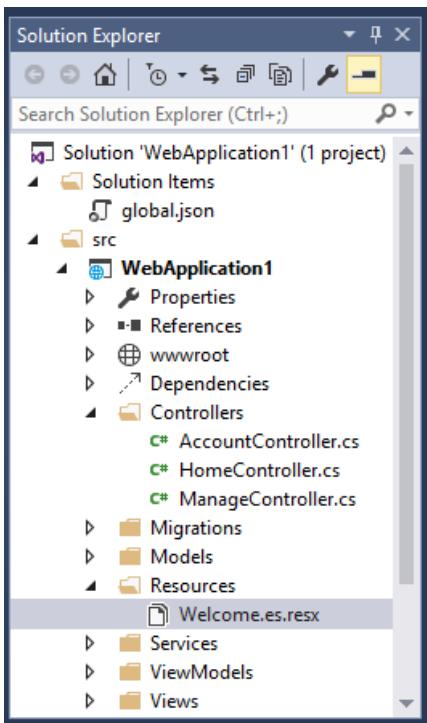

2. In the **Search installed templates** box, enter "resource" and name the file.

3. Enter the key value (native string) in the **Name** column and the translated string in the **Value** column.

	Name	Value	Comment
*	Hello	Hola	

Visual Studio shows the *Welcome.es.resx* file.

## Resource file naming

Resources are named for the full type name of their class minus the assembly name. For example, a French resource in a project whose main assembly is `LocalizationWebsite.Web.dll` for the class `LocalizationWebsite.Web.Startup` would be named `Startup.fr.resx`. A resource for the class `LocalizationWebsite.Web.Controllers.HomeController` would be named `Controllers.HomeControllerfr.resx`. If your targeted class's namespace isn't the same as the assembly name you will need the full type name. For example, in the sample project a resource for the type `ExtraNamespace.Tools` would be named `ExtraNamespace.Tools.fr.resx`.

In the sample project, the `ConfigureServices` method sets the `ResourcesPath` to "Resources", so the project relative path for the home controller's French resource file is `Resources/Controllers/HomeControllerfr.resx`. Alternatively, you can use folders to organize resource files. For the home controller, the path would be `Resources/Controllers/HomeControllerfr.resx`. If you don't use the `ResourcesPath` option, the `.resx` file would go in the project base directory. The resource file for `HomeController` would be named `Controllers.HomeControllerfr.resx`. The choice of using the dot or path naming convention depends on how you want to organize your resource files.

RESOURCE NAME	DOT OR PATH NAMING
Resources/Controllers.HomeController.fr.resx	Dot
Resources/Controllers/HomeController.fr.resx	Path

Resource files using `@inject IViewLocalizer` in Razor views follow a similar pattern. The resource file for a view can be named using either dot naming or path naming. Razor view resource files mimic the path of their associated view file. Assuming we set the `ResourcesPath` to "Resources", the French resource file associated with the `Views/Home/About.cshtml` view could be either of the following:

- Resources/Views/Home/About.fr.resx
- Resources/Views.Home.About.fr.resx

If you don't use the `ResourcesPath` option, the `.resx` file for a view would be located in the same folder as the view.

### RootNamespaceAttribute

The `RootNamespace` attribute provides the root namespace of an assembly when the root namespace of an assembly is different than the assembly name.

If the root namespace of an assembly is different than the assembly name:

- Localization does not work by default.
- Localization fails due to the way resources are searched for within the assembly. `RootNamespace` is a build-time value which is not available to the executing process.

If the `RootNamespace` is different from the `AssemblyName`, include the following in `AssemblyInfo.cs` (with parameter values replaced with the actual values):

```
using System.Reflection;
using Microsoft.Extensions.Localization;

[assembly: ResourceLocation("Resource Folder Name")]
[assembly: RootNamespace("App Root Namespace")]
```

The preceding code enables the successful resolution of resx files.

## Culture fallback behavior

When searching for a resource, localization engages in "culture fallback". Starting from the requested culture, if not found, it reverts to the parent culture of that culture. As an aside, the `CultureInfo.Parent` property represents the parent culture. This usually (but not always) means removing the national signifier from the ISO. For example, the dialect of Spanish spoken in Mexico is "es-MX". It has the parent "es"—Spanish non-specific to any country.

Imagine your site receives a request for a "Welcome" resource using culture "fr-CA". The localization system looks for the following resources, in order, and selects the first match:

- `Welcome.fr-CA.resx`
- `Welcome.fr.resx`
- `Welcome.resx` (if the `NeutralResourcesLanguage` is "fr-CA")

As an example, if you remove the ".fr" culture designator and you have the culture set to French, the default

resource file is read and strings are localized. The Resource manager designates a default or fallback resource for when nothing meets your requested culture. If you want to just return the key when missing a resource for the requested culture you must not have a default resource file.

### Generate resource files with Visual Studio

If you create a resource file in Visual Studio without a culture in the file name (for example, `Welcome.resx`), Visual Studio will create a C# class with a property for each string. That's usually not what you want with ASP.NET Core. You typically don't have a default `.resx` resource file (a `.resx` file without the culture name). We suggest you create the `.resx` file with a culture name (for example `Welcome.fr.resx`). When you create a `.resx` file with a culture name, Visual Studio won't generate the class file. We anticipate that many developers won't create a default language resource file.

### Add other cultures

Each language and culture combination (other than the default language) requires a unique resource file. You create resource files for different cultures and locales by creating new resource files in which the ISO language codes are part of the file name (for example, `en-us`, `fr-ca`, and `en-gb`). These ISO codes are placed between the file name and the `.resx` file extension, as in `Welcome.es-MX.resx` (Spanish/Mexico).

## Implement a strategy to select the language/culture for each request

### Configure localization

Localization is configured in the `ConfigureServices` method:

```
services.AddLocalization(options => options.ResourcesPath = "Resources");

services.AddMvc()
    .AddViewLocalization(LanguageViewLocationExpanderFormat.Suffix)
    .AddDataAnnotationsLocalization();
```

- `AddLocalization` Adds the localization services to the services container. The code above also sets the resources path to "Resources".
- `AddViewLocalization` Adds support for localized view files. In this sample view localization is based on the view file suffix. For example "fr" in the `Index.fr.cshtml` file.
- `AddDataAnnotationsLocalization` Adds support for localized `DataAnnotations` validation messages through `IStringLocalizer` abstractions.

### Localization middleware

The current culture on a request is set in the localization [Middleware](#). The localization middleware is enabled in the `Configure` method. The localization middleware must be configured before any middleware which might check the request culture (for example, `app.UseMvcWithDefaultRoute()` ).

```

var supportedCultures = new[]
{
    new CultureInfo(enUSCulture),
    new CultureInfo("en-AU"),
    new CultureInfo("en-GB"),
    new CultureInfo("en"),
    new CultureInfo("es-ES"),
    new CultureInfo("es-MX"),
    new CultureInfo("es"),
    new CultureInfo("fr-FR"),
    new CultureInfo("fr"),
};

app.UseRequestLocalization(new RequestLocalizationOptions
{
    DefaultRequestCulture = new RequestCulture(enUSCulture),
    // Formatting numbers, dates, etc.
    SupportedCultures = supportedCultures,
    // UI strings that we have localized.
    SupportedUITcultures = supportedCultures
});

app.UseStaticFiles();
// To configure external authentication,
// see: http://go.microsoft.com/fwlink/?LinkID=532715
app.UseAuthentication();
app.UseMvcWithDefaultRoute();

```

`UseRequestLocalization` initializes a `RequestLocalizationOptions` object. On every request the list of `RequestCultureProvider` in the `RequestLocalizationOptions` is enumerated and the first provider that can successfully determine the request culture is used. The default providers come from the `RequestLocalizationOptions` class:

1. `QueryStringRequestCultureProvider`
2. `CookieRequestCultureProvider`
3. `AcceptLanguageHeaderRequestCultureProvider`

The default list goes from most specific to least specific. Later in the article we'll see how you can change the order and even add a custom culture provider. If none of the providers can determine the request culture, the `DefaultRequestCulture` is used.

## QueryStringRequestCultureProvider

Some apps will use a query string to set the [culture and UI culture](#). For apps that use the cookie or Accept-Language header approach, adding a query string to the URL is useful for debugging and testing code. By default, the `queryStringRequestCultureProvider` is registered as the first localization provider in the `RequestCultureProvider` list. You pass the query string parameters `culture` and `ui-culture`. The following example sets the specific culture (language and region) to Spanish/Mexico:

```
http://localhost:5000/?culture=es-MX&ui-culture=es-MX
```

If you only pass in one of the two (`culture` or `ui-culture`), the query string provider will set both values using the one you passed in. For example, setting just the culture will set both the `Culture` and the `UICulture`:

```
http://localhost:5000/?culture=es-MX
```

## CookieRequestCultureProvider

Production apps will often provide a mechanism to set the culture with the ASP.NET Core culture cookie. Use the `MakeCookieValue` method to create a cookie.

The `CookieRequestCultureProvider` `DefaultCookieName` returns the default cookie name used to track the user's preferred culture information. The default cookie name is `.AspNetCore.Culture`.

The cookie format is `c=%LANGCODE%|uic=%LANGCODE%`, where `c` is `Culture` and `uic` is `UICulture`, for example:

```
c=en-UK|uic=en-US
```

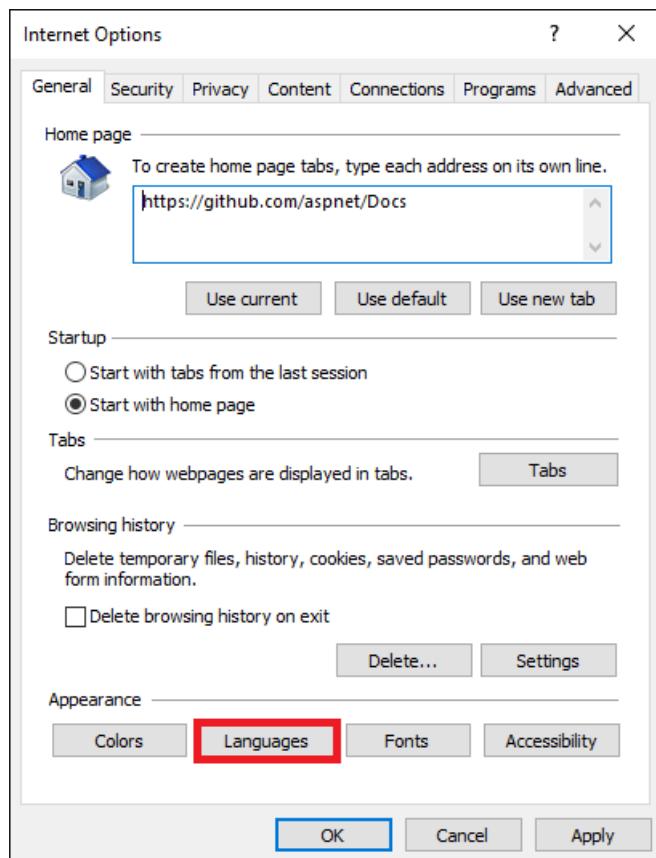

If you only specify one of culture info and UI culture, the specified culture will be used for both culture info and UI culture.

### The Accept-Language HTTP header

The [Accept-Language header](#) is settable in most browsers and was originally intended to specify the user's language. This setting indicates what the browser has been set to send or has inherited from the underlying operating system. The Accept-Language HTTP header from a browser request isn't an infallible way to detect the user's preferred language (see [Setting language preferences in a browser](#)). A production app should include a way for a user to customize their choice of culture.

### Set the Accept-Language HTTP header in IE

1. From the gear icon, tap **Internet Options**.
2. Tap **Languages**.

3. Tap **Set Language Preferences**.
4. Tap **Add a language**.
5. Add the language.
6. Tap the language, then tap **Move Up**.

### Use a custom provider

Suppose you want to let your customers store their language and culture in your databases. You could write a provider to look up these values for the user. The following code shows how to add a custom provider:

```

private const string enUSCulture = "en-US";

services.Configure<RequestLocalizationOptions>(options =>
{
    var supportedCultures = new[]
    {
        new CultureInfo(enUSCulture),
        new CultureInfo("fr")
    };

    options.DefaultRequestCulture = new RequestCulture(culture: enUSCulture, uiCulture: enUSCulture);
    options.SupportedCultures = supportedCultures;
    options.SupportedUICultures = supportedCultures;

    options.RequestCultureProviders.Insert(0, new CustomRequestCultureProvider(async context =>
    {
        // My custom request culture logic
        return new ProviderCultureResult("en");
    }));
});

```

Use `RequestLocalizationOptions` to add or remove localization providers.

## Set the culture programmatically

This sample **Localization.StarterWeb** project on [GitHub](#) contains UI to set the `Culture`. The `Views/Shared/_SelectLanguagePartial.cshtml` file allows you to select the culture from the list of supported cultures:

```

@using Microsoft.AspNetCore.Builder
@using Microsoft.AspNetCore.Http.Features
@using Microsoft.AspNetCore.Localization
@using Microsoft.AspNetCore.Mvc.Localization
@using Microsoft.Extensions.Options

@inject IViewLocalizer Localizer
@inject IOptions<RequestLocalizationOptions> LocOptions

 @{
    var requestCulture = Context.Features.Get<IRRequestCultureFeature>();
    var cultureItems = LocOptions.Value.SupportedUICultures
        .Select(c => new SelectListItem { Value = c.Name, Text = c.DisplayName })
        .ToList();
    var returnUrl = string.IsNullOrEmpty(Context.Request.Path) ? "~/" : $"~{Context.Request.Path.Value}";
}

<div title="@Localizer["Request culture provider:"] @requestCulture?.Provider?.GetType().Name">
    <form id="selectLanguage" asp-controller="Home"
        asp-action="SetLanguage" asp-route-returnUrl="@returnUrl"
        method="post" class="form-horizontal" role="form">
        <label asp-for="@requestCulture.RequestCulture.UICulture.Name">@Localizer["Language:"]</label>
        <select name="culture"
            onchange="this.form.submit();"
            asp-for="@requestCulture.RequestCulture.UICulture.Name" asp-items="cultureItems">
        </select>
    </form>
</div>

```

The `Views/Shared/_SelectLanguagePartial.cshtml` file is added to the `footer` section of the layout file so it will be available to all views:

```

<div class="container body-content" style="margin-top:60px">
    @RenderBody()
    <hr>
    <footer>
        <div class="row">
            <div class="col-md-6">
                <p>&copy; @System.DateTime.Now.Year - Localization.StarterWeb</p>
            </div>
            <div class="col-md-6 text-right">
                @await Html.PartialAsync("_SelectLanguagePartial")
            </div>
        </div>
    </footer>
</div>

```

The `SetLanguage` method sets the culture cookie.

```

[HttpPost]
public IActionResult SetLanguage(string culture, string returnUrl)
{
    Response.Cookies.Append(
        CookieRequestCultureProvider.DefaultCookieName,
        CookieRequestCultureProvider.MakeCookieValue(new RequestCulture(culture)),
        new CookieOptions { Expires = DateTimeOffset.UtcNow.AddYears(1) }
    );

    return LocalRedirect(returnUrl);
}

```

You can't plug in the `_SelectLanguagePartial.cshtml` to sample code for this project. The **Localization.StarterWeb** project on [GitHub](#) has code to flow the `RequestLocalizationOptions` to a Razor partial through the [Dependency Injection](#) container.

## Globalization and localization terms

The process of localizing your app also requires a basic understanding of relevant character sets commonly used in modern software development and an understanding of the issues associated with them. Although all computers store text as numbers (codes), different systems store the same text using different numbers. The localization process refers to translating the app user interface (UI) for a specific culture/locale.

[Localizability](#) is an intermediate process for verifying that a globalized app is ready for localization.
